THE DYNAMIC QUANTIZATION of GRAVITY 
and the COSMOLOGICAL CONSTANT PROBLEM

S.N. Vergeles

Landau Institute for Theoretical Physics, Russian Academy of Sciences, Chernogolovka, Moskow region, 142432 Russia

After a brief outlook of the dynamic quantization method and application of the method to gravity the idea of natural solution of cosmological constant problem in inflating Universe is presented.
PACS: 04.60.-m, 03.70.+k.

1. Introduction

A new Dynamic Method for quantizing generally covariant theories has been proposed in a series of work [1-2]. The study of two-dimensional models, such as the two-dimensional bosonic string [3] and two-dimensional gravity interacting with matter [4], from the standpoint of this method has led, in the first place, to anomaly-free quantization of these models \(^2\) and, in the second place, to further elaboration of the Dynamic quantization method itself. Here we present the dynamic quantization method and its application to four-dimensional gravity. This is done in Sections 2 and 3. The main purpose of the present paper is an attempt to solve the cosmological constant problem in the framework of the theory of gravity quantized by the dynamic method in an inflating Universe. We show in Section 4 that since the number of physical degrees of freedom is finite under Dynamic quantization (in a closed model), the quantum fluctuations in quantum Einstein equation ”die out” with time in the inflating Universe. This result is valid to all orders in the Planck scale \(l_P\).

Let’s outline shortly the cosmological constant problem \(^3\).

Consider Einstein equation with \(\Lambda\)-term (\(\hbar = c = 1\)):

\[
R_{\mu\nu} - \frac{1}{2}g_{\mu\nu}R = 8\pi G T_{\mu\nu} + \Lambda g_{\mu\nu}.
\]

Here \(T_{\mu\nu}\) is energy-momentum tensor of the matter and \(\Lambda\) is some constant parameter having the dimension \([cm^{-2}]\). In the used unit system the Newtonian gravitational constant

\[G \sim l_P^2 \sim 2,5\cdot10^{-66} cm^2,\]

and according to experimental data the mean energy density today is of the order

\[T_{\mu\nu} \sim \rho_1 \sim 10^8 cm^{-4} \longrightarrow 8\pi G T_{\mu\nu} \sim 5\cdot10^{-57} cm^{-2},\]

\(^{1}\text{e-mail:vergeles@itp.ac.ru}\)
\(^{2}\text{See [5] for a discussion of anomaly-free quantization of two-dimensional gravity from a standpoint close to that of the present author.}\)
\(^{3}\text{The reader can find the review of the problem in [6]}\)
\[ \Lambda \sim 10^{-56} \text{cm}^{-2}. \]  \hspace{1cm} (4)

Thus, if Einstein equation (1) is used for description of the today dynamics of Universe, the quantities in its right hand side are of the same order indicated in (3) and (4).

Now let us estimate the possible value of the right hand side of Eq. (1) in the framework of canonical quantum field theory. For simplicity consider energy-momentum tensor in quantum electrodynamics in flat spacetime:

\[ T_{\mu \nu} = \frac{1}{4\pi} \left( F_{\mu \lambda} F^\lambda_{\nu} - \frac{1}{4} \eta_{\mu \nu} F^2 \right) + i \frac{e}{2} \left( \bar{\psi} \gamma_{(\mu} \nabla_{\nu)} \psi - \nabla_{\nu} \bar{\psi} \gamma_{\mu} \psi \right). \]  \hspace{1cm} (5)

Casimir effect, predicted in [7] and experimentally verified in [8], shows for reality of zero-point energies. Moreover, the attempts to drop out zero-point energies by appropriate normal ordering of creating and annihilating operators in energy-momentum tensor fail for many of reasons (the discussion of this problem see, for example, in [9]). Thus, at estimating vacuum expectation value of energy-momentum tensor (5), it should not be performed normal ordering of creating and annihilating operators in (5). Thus we obtain for vacuum expectation value of tensor (5) in free theory:

\[ \langle T_{\mu \nu} \rangle_0 = \frac{d^{(3)}k}{(2\pi)^3} \frac{k_\mu k_\nu}{k^0 = |k|} \left( \frac{2k_\mu k_\nu}{k^0} |_{k^0 = \sqrt{m^2 + k^2}} \right). \]  \hspace{1cm} (6)

Here \( m \) is the electron mass. The first item in (6) gives the positive contribution but the second item gives the negative contribution since these items give the boson and fermion contributions to vacuum energy, respectively. If integration in (6) is restricted by Planck scale, \( k_{\text{max}} \sim l_P^{-1} \), then from (6) and (2) it follows:

\[ 8\pi G \langle T_{\mu \nu} \rangle_0 \sim l_P^{-2} \sim 10^{66} \text{cm}^{-2}. \]  \hspace{1cm} (7)

It is clear that the interaction of fields doesn’t changes qualitatively the estimation (7). From (7) and (3) we see that the contribution to the righthand side of Eq. (1) estimated in the framework of canonical quantum field theory is larger about 10^{120} times in comparison with the experimental estimations.

It is known that in globally supersimmetric field theories the vacuum energy is equal to zero [10]. Indeed, in flat spacetime the anticommutation relations

\[ \{ Q_\alpha, Q_\beta^\dagger \} = (\sigma_\mu)_{\alpha \beta} P^\mu. \]  \hspace{1cm} (8)

take place. Here \( Q_\alpha \) are supersimmetry generators, \( \alpha, \beta \) are spinor indexes, \( \sigma_1, \sigma_2 \) and \( \sigma_3 \) are the Pauli matrices, \( \sigma_0 = 1 \), and \( P^\mu \) is the energy-momentum 4-vector operator. If supersimmetry is unbroken, then the vacuum state \( |0\rangle \) satisfies

\[ Q_\alpha |0\rangle = Q_\alpha^\dagger |0\rangle = 0, \]  \hspace{1cm} (9)

and (8) and (9) imply

\[ \langle P^\mu \rangle_0 = 0. \]  \hspace{1cm} (10)

The equality (10) means that the total sum of zero-point energies in unbroken globally supersimmetric field theories is rigorously equal to zero.
However, even if supersymmetry takes place on fundamental level, it is broken on experimentally tested scales. If one assumes that supersymmetry is unbroken on the scales greater than \( k_{SS} \sim 10^{17} \text{ cm}^{-1} (\sim 10^3 \text{ GeV}) \), then even in this case the contribution to the right hand side of Eq. (1) from zero-point energies of all normal modes with energies less then \( k_{SS} \) will exceed experimentally known value about \( 10^{58} \) times.

It follows from the said above that any calculation in the framework of canonical quantum field theory leads to unacceptable large vacuum expectation value of energy momentum tensor. The considered catastrophe isn’t solved at present in superstring theory.

It should be noted here that the problem of cosmological constant is solved in original theory of G. Volovik [11]. In this theory the gravitons and other excitations are the quasiparticles in a more fundamental quantum system — quantum fluid of the type \(^3\text{He}\) in superfluid phase. Another approach to the problem of cosmological constant in the frame of M-theory is developed in works [14]. Interesting idea about solution of the problem is presented in [15].

Specific results of the application of the Dynamic quantization method to the above mentioned two-dimensional theories [3, 4], obtained by explicit constructions and direct calculations, justify the abstract assumptions and axioms on which this method is based.

We shall explain the ideology and logical scheme of the Dynamic method taking account of the experience in quantizing two-dimensional gravity.

The key point in the quantization of two-dimensional gravity was the construction of a complete set of such operators \( \{A_n, B_n, \ldots\} \), designated below as \( \{A_N, A^\dagger_N\} \), which possess the following properties:

1) The operators \( A_N \) and \( A^\dagger_N \) are Hermithian conjugates of one another and

\[
[A_N, A_M] = 0, \quad [A_N, A^\dagger_M] = \delta_{NM}.
\] (11)

2) The set of operators \( \{A_N, A^\dagger_N\} \) describes all physical dynamical degrees of freedom of a system.

3) Each operator from the set \( \{A_N, A^\dagger_N\} \) commutes weakly with all first class constraints or with the complete Hamiltonian of the theory.

Quantization is performed directly using the operators \( \{A_N, A^\dagger_N\} \). It means that the space of physical states is created using the operators \( \{A_N, A^\dagger_N\} \) from the ground state and all operators are expressed in terms of the operators \( \{A_N, A^\dagger_N\} \), as well as in terms of the operators describing the gauge degrees of freedom. However, in the theory of two-dimensional gravity the operators \( \{A_N, A^\dagger_N\} \) were constructed explicitly (i.e., they were expressed explicitly in terms of the fundamental dynamical variables), in more realistic theories this problem is hardly solvable. Therefore, the set of operators \( \{A_N, A^\dagger_N\} \) with properties 1)–3) must be introduced axiomatically. Conversely, the properties 1)–3) make it possible, in principle, to express the initial variables in terms of the convenient operators \( \{A_N, A^\dagger_N\} \).

However, in contrast to the two-dimensional theory of gravity, regularization is necessary in real models of gravity. In the Dynamic quantization method, regularization is carried out precisely in terms of the operators \( \{A_N, A^\dagger_N\} \). As will be shown below, such regularization is natural in generally covariant theories, since it preserves the form of the Heisenberg equations and thereby also the general covariance of the theory.
As a result we have the regularized general covariant theory describing quantum gravity, the main property of which is the finiteness of physical degrees of freedom contained in each finite volume. Evidently, the theory of discrete quantum gravity defined on the lattice (simplicial complexes) possess the same properties (see, for example, [12] and references here). Therefore, one can think that the theory of gravity quantized by dynamic quantization method is the continuous limit of discrete quantum gravity discussed in [12].

2. Method of dynamic quantization

Let’s consider a generally covariant field theory. Let us assume that in this theory the Hamiltonian in the classical limit is an arbitrary linear combination of the first class constraints and there are no the second class constraints.

Let \( \{ \Phi^{(i)}(x), P^{(i)}(x) \} \) be a complete set of fundamental fields of the theory and their canonically conjugate momenta, in terms of which all other physical quantities and fields of the theory are expressed. Here the index \( (i) \) enumerates the type of fields. For example, for some \( (i) \) these can be either 6 spatial components of the metric tensor \( g_{ij}(x) \) or the scalar field \( \phi(x) \) or the Dirac field \( \psi(x) \) etc. The set of fields \( \{ \Phi^{(i)}(x) \} \) is a complete set of the mutually commuting (at least in formal unregularized theory) fundamental fields of the theory.

Next, to simplify the notation the index \( i \) will be omitted. It can be assumed that the variable \( x \) includes, besides the spatial coordinates, the index \( i \) also.

The construction of a quantum theory by the Dynamic method is based on the following natural assumptions relative to the structure of the space \( F \) of the physical states of the theory.

1. All states of the theory having physical sense are obtained from the ground state \( |0\rangle \) using the creation operators \( A_{N}^{\dagger} \):

\[
| n_1, N_1; \ldots; n_s, N_s \rangle = (n_1! \cdots n_s!)^{-\frac{1}{2}} \cdot (A_{N_1}^{\dagger})^{n_1} \cdots (A_{N_s}^{\dagger})^{n_s} |0\rangle ,
\]

\[
A_{N} |0\rangle = 0 .
\] (12)

States (12) form an orthonormal basis of the space \( F \) of physical states of the theory.

The numbers \( n_1, \ldots, n_s \) assume integer values and are called occupation numbers.

2. The set of states \( \Phi(x) | n_1, N_1; \ldots; n_s, N_s \rangle \), where the set of numbers \( n_1, N_1; \ldots; n_s, N_s \) is fixed, contains a superposition of all states of the theory, for which one of the occupation number differs in modulus by one and all other occupation numbers equal to the occupation numbers of state (12).

Here the operators \( A_{N}^{\dagger} \) and their conjugates \( A_{N} \) possess the standard commutation properties (11). The operators \( \{ A_{N}, A_{N}^{\dagger} \} \), generally speaking, can be bosonic or fermionic. If the creation and annihilation operators follow the Fermi statistics, then the anticommutator is taken in (11). For the case of compact spaces which is interesting for us, we can assume without loss of generality that the index \( N \), enumerating the creation and
annihilation operators, belongs to a discrete finite-dimensional lattice. A norm can be easily introduced in the space of indexes \( N \).

Since states (12) are physical, they satisfy the relations

\[
\mathcal{H}_T | n_1, N_1; \ldots; n_s, N_s \rangle = 0 ,
\]

where \( \mathcal{H}_T \) is the complete Hamiltonian of the theory. We assume that \( \mathcal{H}_T = \sum \varepsilon \chi_{\varepsilon} \), where \( \{ \chi_{\varepsilon} \} \) is the complete set of the first class constraints and \( \{ v_{\varepsilon} \} \) is arbitrary set of Lagrange multipliers.

Equations (12) and (13) are compatible if and only if the following relations are valid:

\[
[A_N, \chi_{\varepsilon}] = \sum_{\Pi} c_{N\Pi} \chi_{\Pi} ,
\]

\[
[A_N^\dagger, \chi_{\varepsilon}] = -\sum_{\Pi} \chi_{\Pi} c_{N\Pi}^\dagger = \sum_{\Pi} \tilde{c}_{N\Pi} \chi_{\Pi} ,
\]

where the coefficients \( c_{N\Pi} \), \( \tilde{c}_{N\Pi} \) in Eq. (14) generally are operators, the arrangement of the multiplies in the right hand sides of Eqs. (14) is important.

Let \( (A_N^\dagger, A_N) \) be a pair of bose or fermi creation and annihilation operators creating or annihilating the state with the wave function \( \psi_N(x) \). According to (14) we have:

\[
[A_N, \mathcal{H}_T] = \sum_{\Xi, \Pi} r_{N\Xi\Pi} v_{\Xi} \chi_{\Pi} \longleftrightarrow [A_N^\dagger, \mathcal{H}_T] = -\sum_{\Xi, \Pi} \chi_{\Pi} v_{\Xi}^* r_{N\Xi\Pi} .
\]

Let an arbitrary operator \( \Phi \) be represented as a normal ordered power series in operators \( (A_N^\dagger, A_N) \):

\[
\Phi = \Phi' + \phi_N A_N + A_N^\dagger \tilde{\phi}_N ,
\]

By definition here the operator \( \Phi' \) does not depend on the operators \( (A_N^\dagger, A_N) \):

\[
[\Phi', A_N^\dagger] = [\Phi', A_N] = 0 .
\]

It follows from Eqs. (15)-(17) that

\[
[\Phi, \mathcal{H}_T] = [\Phi', \mathcal{H}_T'] + \sum_{\Xi} (q_{\Xi} \chi_{\Xi} + \chi_{\Xi} q_{\Xi}) + (p_N A_N + A_N^\dagger \tilde{p}_N) .
\]

Here the total Hamiltonian \( \mathcal{H}_T \) is represented according to (16), so that \( \mathcal{H}_T' \) does not depend on the operators \( (A_N^\dagger, A_N) \). To verify Eq. (18) let’s write out the following chain of equalities:

\[
[\Phi, \mathcal{H}_T] = [\Phi', \mathcal{H}_T] + \left( \phi_N [A_N, \mathcal{H}_T] + [A_N^\dagger, \mathcal{H}_T] \tilde{\phi}_N \right) + \left( [\phi_N, \mathcal{H}_T] A_N + A_N^\dagger [\tilde{\phi}_N, \mathcal{H}_T] \right) .
\]

(19)

As a consequence of Eqs. (15) the second item in the right hand side of Eq. (19) has the same structure as the second item in the right hand side of Eq. (18). Evidently, the last items in the right hand side of Eq. (19) has the same structure as the last items in the right hand side of Eq. (18). Now let’s write out the following identity:

\[
[\Phi', \mathcal{H}_T] \equiv [\Phi', \mathcal{H}_T'] + [\Phi', \mathcal{H}_T - \mathcal{H}_T'] .
\]

(20)

By definition

\[
\mathcal{H}_T - \mathcal{H}_T' = h_N A_N + A_N^\dagger \tilde{h}_N .
\]

(21)
It follows from (17) and (21) that
\[
[\Phi', \mathcal{H}_T - \mathcal{H}'_T] = [\Phi', h_N] A_N + A_N^\dagger [\Phi', \tilde{h}_N].
\] (22)

Combining Eqs. (19), (20) and (22) we come to the Eq. (18).

Now let’s impose an additional pair of second class constraints
\[
A_N = 0, \quad A_N^\dagger = 0.
\] (23)

By definition under the constraints (23) any operator \(\Phi\) is reduced to the operator \(\Phi'\) in (16). The Dirac bracket arising under the constraints (23) is defined according to the following equality:
\[
[\Phi, \mathcal{F}]^* \equiv [\Phi', \mathcal{F}'].
\] (24)

The remarkable property of the considered theory is the fact that
\[
[\Phi, \mathcal{H}_T]^* \approx [\Phi, \mathcal{H}_T].
\] (25)

Here the approximate equality means that after the imposition of all first and second class constraints the operators in the both sides of Eq. (25) coincide, that is the weak equality (25) reduces to the strong one. Relation (25) follows immediately from Eqs. (15) and (24). Eq. (25) means that the Heisenberg equation
\[
i\dot{\Phi} = [\Phi, \mathcal{H}_T]^*
\]
for any field in reduced theory coincides weakly with corresponding Heisenberg equation in nonreduced theory. Evidently, this remarkable conclusion retains true under imposition of any number of pairs of the second class constraints of type (23)4.

The above-stated bring to the following idea of ultraviolet regularization of quantum theory of gravity. Let a local field \(\Phi(x)\) create and annihilate particles in the states with wave functions \(\{\phi_N(x)\}\) by creation and annihilation operators \(\{A_N^\dagger, A_N\}\) (for simplicity the field \(\Phi\) is assumed to be real). The physical space of states is invariant relative to the action of creation and annihilation operators. Therefore there is the possibility of imposing the second class constraints of the type (23) for any number of pairs of these operators without changing Heisenberg equations of motion. Let the high-frequency (in some sense) wave functions \(\{\phi_N(x)\}_{|N| > N_0}\) have the value of index \(|N| > N_0\). The ultraviolet regularization of the theory is performed by imposing the constraints of the type (23) for all \(|N| > N_0\). It is very important that under the constraints the regularized equations of motion and first class constraints preserve their canonical form. Hence the equations of regularized theory are general covariant, i.e. they conserve their form under the general coordinate transformations and local frame transformations.

Since unregularized theory of quantum gravity is mathematically meaningless, so it seems correct the direct definition of regularized theory by means of introduction of natural axioms.

\textbf{Axiom 1.} All states of the theory which are physically meaningful are obtained from the ground state \(|0\rangle\) using the creation operators \(A_N^\dagger\) with \(|N| < N_0\) :\

\[
|n_1, N_1; \ldots ; n_s, N_s\rangle = (n_1! \times \cdots \times n_s!)^{-\frac{1}{2}} \cdot (A_{N_1}^\dagger)^{n_1} \times \cdots \times (A_{N_s}^\dagger)^{n_s} |0\rangle,
\]

\(^4\)In Appendix we give the simple example in which the imposition of second class constraints of type (23) does not change equations of motion.
\[ A_N |0\rangle = 0. \quad (26) \]

States (26) form an orthonormal basis of the space $F$ of physical states of the theory.

**Axiom 2.** The dynamical variables $\Phi(x)$ transfer state (26) with fixed values of numbers $(n_1, N_1; \ldots; n_s, N_s)$ into a superposition of the states of the theory of form (26), containing all states in which one of the occupation numbers is different in modulus by one and all other occupation numbers are identical to those of state (26).

**Axiom 3.** The equations of motion and constraints for the physical fields $\{\Phi(x), P(x)\}$ have the same form, to within the arrangement of the operators, as the corresponding classical equations and constraints.

Further we suppose that the momentum variables $P(x)$ are expressed through the fundamental field variables $\Phi(x)$ and their time derivatives $\dot{\Phi}(x)$, so that the Lagrange equations instead of Hamilton equations are used.

Let’s assume, further, that the ground state $|0\rangle$ is a coherent state with respect to the gauge degrees of freedom. It means that the quantum fluctuations of the gauge degrees of freedom are not significant and their dynamics in fact is classical.

Let’s emphasize that this assumption is related with the fact of noncompactness of the gauge group. (Since the group of general linear transformations is noncompact, so the gauge group in the theory of gravity is noncompact.) In this relation it is interesting to demonstrate the transformation of quantum particle to classical one in the course of time in the case of noncompact dynamics. Let $x$ and $p$ be Heisenberg coordinate and momentum operators of a free nonrelativistic particle with mass $m$ moving in noncompact flat space. Then

\[ p = p_0, \quad x = x_0 + \frac{p_0}{m} t, \]

where $t$ is the time, and $x_0$ and $p_0$ are constant operators, satisfying the commutation relation $[x_0, p_0] = i\hbar$. It is obvious that if $\langle p_0 \rangle \neq 0$, then as $t \to \infty$

\[ \frac{\langle x \rangle \langle p \rangle}{\langle [x, p] \rangle} \to \infty, \]

which means that the dynamics of the free particle in the course of time becomes quasi-classical.

The quasiclassical character of dynamics of gauge degrees of freedom seems true only for noncompact gauge groups. On the contrary, the motion in compact gauge group (such as in Yang-Mills theory) can not be regarded as classical.

Let’s consider, for example, the quantized electrodynamic field in noncovariant Coulomb gauge. In this gauge only the degrees of freedom describing photons fluctuate, but the gauge (longitudinal) degrees of freedom are defined unambiguously through the electric current. Thus, the gauge degrees of freedom in QED does not fluctuate, effectively they are classical. On the other hand, in high-temperature confinement phase in QED on a lattice the high-temperature expansion is valid. In this case the gauge degrees of freedom can not be regarded as classical. So our assumption about classical behavior of gauge degrees of freedom in quantum gravity is equivalent to the assumption that quantum gravity is in noncompact phase.
Consider any fundamental field:
\[
\Phi(x) = \Phi_{(cl)}(x) + \sum_{|N|<N_0} [\phi_N(x) A_N + \phi_N^*(x) A_N^d] + \ldots . \tag{27}
\]

On the right-hand side of Eq. (27) all functions \( \Phi_{(cl)}(x) \), \( \phi_N(x) \), and so on are c-number functions.

This follows from the assumption about the quasiclassical character of the dynamics of gauge degrees of freedom.

Now we can supplement our system of axioms by the following supposition: field (27) is used in axioms 1-3. The fields \( \Phi_{(cl)}(x) \), \( \phi_N(x) \), and so on satisfy certain equations which can be obtained uniquely from the Lagrange equations of motion, if the expansion of the field \( \Phi(x) \) in form (27) is substituted into them and then, after normal ordering of the operators \( \{ A_N, A_N^d \} \), the coefficients of the various powers of the generators of the Heisenberg algebra \( \{ A_N, A_N^d \} \) are equated to zero. As a result of the indicated normal ordering, the relations arise between the higher order coefficient functions and the lower order coefficient functions in expansion (27). We obtain an infinite chain of equations for the coefficient functions \( \{ \Phi_{(cl)}(x), \phi_N(x), \psi_N(x), \ldots \} \). The latter conjecture can be introduced with the aid of the following axiom, replacing axiom 3.

**Axiom 3’.** The equations of motion for the quantized fields (26), up to the ordering of the quantized fields, have the same form as the corresponding classical equations of motion.

### 3. Dynamic quantization of gravity

We shall now apply the quantization scheme developed above to the theory of gravity.

Let’s consider the theory of gravity with a \( \Lambda \) term which is coupled minimally with the Dirac field. The action of such a theory has the form
\[
S = -\frac{1}{l_P^2} \int d^4 x \sqrt{-g} \left( R + 2\Lambda \right) + \int d^4 x \sqrt{-g} \left\{ \frac{i}{2} e^\mu_a \left( \bar{\psi} \gamma^a D_\mu \psi - D_\mu \bar{\psi} \gamma^a \psi \right) - m \bar{\psi} \psi \right\} \tag{28}
\]

Here \( \{ e^\mu_a \} \) is an orthonormalized basis, \( g_{\mu\nu} \) is the metric tensor, and \( \eta_{ab} = diag(1, -1, -1, -1) \) so that
\[
g_{\mu\nu} e^\mu_a e^\nu_b = \eta_{ab}, \quad R = e^\mu_a e^\nu_b R^{ab}_{\mu\nu},
\]
the 2-form of the curvature is given by
\[
d\omega^{ab} + \omega^a_c \wedge \omega^c_b = \frac{1}{2} R^{ab}_{\mu\nu} dx^\mu \wedge dx^\nu,
\]
where the 1-form \( \omega^a_b = \omega^a_{\mu b} dx^\mu \) is the connection in the orthonormal basis \( \{ e^\mu_a \} \). The spinor covariant derivative is given by the formula
\[
D_\mu \psi = \left( \frac{\partial}{\partial x^\mu} + \frac{1}{2} \omega_{\mu b}^a \sigma^{ab} \right) \psi, \quad \sigma^{ab} = \frac{1}{4} [\gamma^a, \gamma^b],
\]
\( \gamma^a \) are the Dirac matrices:

\[ \gamma^a \gamma^b + \gamma^b \gamma^a = 2 \eta^{ab}. \]

Let’s write out the equations of motion for system (28).

The variation of action (28) relative to the connection gives the equation

\[ \nabla_\mu e^a_\nu - \nabla_\nu e^a_\mu = -\frac{1}{4} l_P^2 e^a_{bcd} e^c_\mu \bar{\psi} \gamma^5 \gamma^d \psi \equiv T^a_{\mu \nu}. \tag{29} \]

In deriving the last equation, we employed the equality

\[ \gamma^a \sigma^{bc} + \sigma^{bc} \gamma^a = -i \varepsilon_{abcd} \gamma^5 \gamma^d \tag{30} \]

Here \( \varepsilon_{abcd} \) is the absolutely antisymmetric tensor, and \( \varepsilon_{0123} = 1 \). The right-hand side of Eq. (29) is the torsion tensor.

We note that torsion (29) possesses the property

\[ T^a_{\nu \mu} \equiv e^a_\nu T^a_{\mu \nu} \equiv 0 \tag{31} \]

Consequently, even though torsion exists in the considered theory, the torsion tensor is not present in the Dirac equation:

\[ (i e^a_\mu \gamma^a D_\mu - m) \psi = 0 \tag{32} \]

The variation of action (28) relative to the orthonormal basis gives the Einstein equation, which we write in the form

\[ R_{\mu \nu} + \Lambda g_{\mu \nu} = \frac{1}{2} l_P^2 \left\{ \frac{i}{2} \left( \bar{\psi} \gamma^c e_{c(\mu} D_{\nu)} \psi - e_{c(\mu} \bar{D}_{\nu)} \psi \gamma^c \psi \right) - \frac{1}{2} m \bar{\psi} \psi g_{\mu \nu} \right\} \tag{33} \]

Here the expression in braces is \((T_{\mu \nu} - 1/2 g_{\mu \nu} T)\), where \( T_{\mu \nu} \) is the energy-momentum tensor on the mass shell (i.e., taking account of the equations of motion of matter — in our case, the Dirac equation (31)).

Equations (29), (30-33), together with the relations

\[ g_{\mu \nu} = \eta_{ab} e^a_\mu e^b_\nu, \quad e^a_\mu e^b_\mu = \delta^b_a \]

form a complete system of classical equations of motion and constraints for system (28).

We now represent the fields as the sum of classical and quantum components:

\[ g_{\mu \nu} = g(\text{cl})_{\mu \nu} + h_{\mu \nu}, \quad e^a_\mu = e^a_{(\text{cl})\mu} + f^a_\mu \tag{34} \]

Assume that the fermion field has no classical component, so that

\[ \psi(x) = \sum_{|N| < N_F} \left( a_N \psi^+_N(x) + b^+_N \psi^-_N(x) \right) + \ldots, \tag{35} \]

where the Fermi creation and annihilation operators satisfy the following anticommutation relations (as usual, only the nonzero relations are written out):

\[ \{ a_M, a^\dagger_N \} = \{ b_M, b^\dagger_N \} = \delta_{M,N}, \quad a_N |0\rangle = b_N |0\rangle = 0. \tag{36} \]
The complete orthonormal set of fermion modes \( \{ \psi_N^{(\pm)}(x) \} \) can be naturally determined as follows. Denote by \( \Sigma^{(3)} \) the spacelike hypersurface, defined by the equation \( t = \text{Const} \), and by \( \Sigma_0^{(3)} \) the hypersurface at \( t = t_0 \). Let the metric in space-time be given by means of the tensor \( g_{\mu\nu} \). This metric induces a metric on \( \Sigma_0^{(3)} \), which in the local coordinates \( x^i, i = 1, 2, 3 \), is represented by the metric tensor \( g_{ij} \). Using the equations

\[
\begin{align*}
3g_{ij,k} &= \gamma_{ik}^l 3g_{lj} + \gamma_{jk}^l 3g_{il}, \\
g_{ij} &= -\sum_{\alpha=1}^{3} e_\alpha^i e_\alpha^j, \\
3\omega_{\alpha\beta i} &= 3g_{ij}^k, \\
\partial_i 3e_\alpha^i + \gamma_{ki}^j 3e_\alpha^j + 3\omega_{\alpha\beta i}^j 3e_\beta^j = 0, \\
3\omega_{\alpha\beta i} &= -3\omega_{\beta\alpha i},
\end{align*}
\]

the connection (without torsion) \( \gamma_{jk}^i \) in local coordinates and a spin connection \( 3\omega_{\alpha\beta i} \) are determined on \( \Sigma_0^{(3)} \). For a Dirac single-particle Hamiltonian we have:

\[
\mathcal{H}_D = -i 3e_\alpha^i \alpha^\alpha (\partial_i + \frac{1}{2} 3\omega_{\beta\gamma i} \frac{1}{4} [\alpha^\beta, \alpha^\gamma]) + m \gamma^0,
\]

\[
\alpha^\beta = \gamma^0 \gamma^\beta
\]

It is easy to check that in the metric

\[
\langle \psi_M, \psi_N \rangle = \int_{\Sigma_0^{(3)}} d^3x \sqrt{-3g} \psi_M^\dagger \psi_N
\]

the operator \( \mathcal{H}_D \) is self-conjugated. Consequently, the solution of the problem for the eigenvalues on \( \Sigma_0^{(3)} \)

\[
\mathcal{H}_D^{(0)}(x) = \pm \varepsilon_N \psi_N^{(\pm)}(x), \quad \varepsilon_N > 0
\]

has a complete set of orthonormal modes in metric (37). The index (0) everywhere means that in the corresponding quantity the fields are taken in the zero approximation with respect to quantum fluctuations.

Note that a one-to-one relation can be established between the positive- and negative-frequency modes by means of the equation

\[
\gamma^0 \gamma^5 \psi_M^{(\pm)} = \psi_M^{(\mp)}
\]

We call the attention to the fact that the scalar product

\[
\langle \psi_M, \psi_N \rangle = \int_{\Sigma^{(3)}} d^3x \sqrt{-g^{(0)}} \psi_M^\dagger \psi_N
\]

is not always the same as the scalar product (37). These scalar products coincide, if the path function \( N = 1 \), which happens, for example, for the metric

\[
g_{0i}^{(0)} = 0, \quad g_{00}^{(0)} = 1.
\]

The scalar product (39) has the advantage over the scalar product (37) that if the modes \( \{ \psi_N^{(\pm)}(x) \} \) satisfy the Dirac equation in the zero approximation with respect to quantum fluctuations (which, according to the exposition below, does indeed happen), then the scalar product (39) is conserved in time.
The field $h_{\mu\nu}$ in Eq.(34) can be expanded as follows:

\[
h_{\mu\nu} = l_P \sum_{|N|<N_0} \left( h_{N\mu\nu} c_N + h^*_{N\mu\nu} c_N^\dagger \right) +
\]

\[+l_P^2 \left\{ \sum_{|N_1|,|N_2|<N_0} \left( h_{N_1N_2\mu\nu} c_{N_1} c_{N_2} + h^*_{N_1N_2\mu\nu} c_{N_1}^\dagger c_{N_2}^\dagger + h_{N_1N_2\mu\nu} c_{N_1}^\dagger c_{N_2} + h^*_{N_1N_2\mu\nu} c_{N_1} c_{N_2}^\dagger \right) +
\]

\[+ \sum_{|N_1|,|N_2|<N_P} \left( h_{N_1N_2\mu\nu} F_{(+)} a_{N_1}^\dagger a_{N_2} + h_{N_1N_2\mu\nu} F_{(-)} b_{N_1}^\dagger b_{N_2} +
\]

\[+ h_{N_1N_2\mu\nu} F_{(+)}^* a_{N_1}^\dagger b_{N_2} + h_{N_1N_2\mu\nu} F_{(-)}^* b_{N_1}^\dagger a_{N_2} \right \} + \ldots \]  

(40)

In Eqs.(34), (35), and (40) the $c$-number coefficient fields $\psi_N^{(+)}$, $g_{(d)\mu\nu}$, $h_{N\mu\nu}$ and so on can be expanded in powers of the Planck scale, for example

\[g_{(d)\mu\nu} = g^{(0)}_{\mu\nu} + l_P^2 g^{(2)}_{(d)\mu\nu} + \ldots \]

Since fields (40) are real, we have

\[h_{N_1N_2\mu\nu} = h_{N_2N_1\mu\nu}, \quad h^*_{N_1N_2\mu\nu} = h^*_{N_2N_1\mu\nu}, \quad h_{N_1N_2\mu\nu} = h_{N_2N_1\mu\nu} \]

(41)

The operators \(\{c_N, c_N^\dagger\}\) satisfy the Bose commutation relations (31). A method for choosing the set of functions \(\{h_{N\mu\nu}\}\) will be discussed below.

According to the dynamic quantization scheme, we must substitute fields (34-35) and (40) into Eqs. (29) and (32-33), after which the operators \(\{A_N, A_N^\dagger\}\) must be normal-ordered and all coefficients of the various powers of these operators and the Planck scale must be set equal to zero.

Thus, we obtain the first of these equations:

\[\nabla_\mu e^{(0)}_\nu a - \nabla_\nu e^{(0)}_\mu a = 0, \quad R^{(0)}_{\mu\nu} + \Lambda g^{(0)}_{\mu\nu} = 0 \]  

(42)

Here and below all raising and lowering of indices are done with the tensors $g^{(0)}_{\mu\nu}$ and $g^{(0)\mu\nu}$. Thus, in the lowest approximation the fields satisfy the classical equations of motion. In the zeroth approximation we also have a series of equations for the fermion modes:

\[(i \gamma^a \lambda^a D^{(0)}_{\mu} - m) \psi^{(0)}_N(\pm) = 0 \]  

(43)

We now introduce the notation

\[K^{(0)\lambda}_\mu \delta^\rho = \left[ -\frac{1}{2} \nabla^{(0)}_\sigma \nabla^{(0)}_{\nu} \delta^\lambda_\mu \delta^\rho_\nu - R^{(0)\lambda}_\mu \delta^\rho_\nu + R^{(0)\rho}_\nu \delta^\lambda_\mu +
\]

\[+ \nabla^{(0)}_\mu \left( \nabla^{(0)\lambda}_\delta \delta^\rho_\nu - \frac{1}{2} \nabla^{(0)}_\nu g^{(0)\lambda\rho} \right) \right] + \left[ \mu \leftrightarrow \nu \right] + 2 \Lambda \delta^\lambda_{[\mu} \delta^\rho_{\nu]}, \]

(44)

\[R^{(0)(2)}_{\mu\nu}(h, h') = \frac{1}{2} \left[ R^{(0)(2)}_{\mu\nu}(h + h', h + h') - R^{(0)(2)}_{\mu\nu}(h, h) - R^{(0)(2)}_{\mu\nu}(h', h') \right] \]  

(45)

It is easily checked that

\[\frac{1}{2} K^{(0)\lambda}_\mu \delta^\rho = \delta(R_{\mu\nu} + \Lambda g_{\mu\nu}) \bigg|_{g_{\mu\nu}=g^{(0)}_{\mu\nu}} \]
where $R_{\mu\nu}^{(0)(2)}(h, h)$ is a quadratic form of the tensor field $h_{\lambda\rho}$ which can be constructed in terms of the second variation of $R_{\mu\nu}$ relative to the metric tensor at the point $g_{\mu\nu}^{(0)}$. Let’s write out the complete form:

$$R_{\mu\nu}^{(0)(2)}(h, h) = \frac{1}{2} \left( h_{\lambda\rho}^{\mu} h_{\lambda\rho}^{\nu} \right) - \frac{1}{2} \left[ h_{\lambda\rho}^{\sigma} \left( h_{\mu\nu}^{\sigma} + h_{\nu\mu}^{\sigma} - h_{\mu\nu}^{\sigma} \right) \right] + \frac{1}{4} \left( \frac{1}{2} h_{\lambda\rho}^{\lambda} \left( h_{\rho\mu}^{\mu} + h_{\rho\nu}^{\mu} - h_{\rho\mu}^{\nu} \right) - \frac{1}{2} \left( h_{\rho\nu}^{\lambda} + h_{\rho\mu}^{\lambda} \right) \left( h_{\lambda\mu}^{\lambda} - h_{\mu\lambda}^{\lambda} \right) \right)$$

Thus, $R_{\mu\nu}^{(0)(2)}(h, h')$ is a symmetric bilinear form with respect to its arguments $h_{\mu\nu}$ and $h'_{\lambda\rho}$, which in what follows are operator fields (40). Thus, here the problem of ordering the operator fields to lowest order has been solved.

Now we can write out the following relations, which follow from the exact quantum equations with the expansion indicated above. To first order in $l_P$ we have

$$\frac{1}{2} K_{\mu\nu}^{(0)} h_{\lambda\rho} = 0 \quad (46)$$

We note that, using Eqs. (42), the operator (44) vanishes on the quantity $(\xi_{\mu\nu} + \xi_{\nu\mu})$. Consequently, the value of the operator (44) on the fields $h_{\mu\nu}$ and $h'_{\mu\nu} = h_{\mu\nu} + \xi_{\mu\nu} + \xi_{\nu\mu}$ coincide for any vector field $\xi_{\mu\nu}$. This fact is a consequence of the gauge invariance of the theory. Using the indicated gauge invariance, any solution of Eq. (46) can be put into the form

$$\nabla_{\nu}^{(0)} h_{\mu} = -\frac{1}{2} \nabla_{\mu}^{(0)} h_{\nu} = 0 \quad (48)$$

In what follows, we shall assume that the field satisfies the gauge condition (48), which is convenient in a number of problems. It is obvious that taking account of the gauge condition (48) the terms in round brackets in operator (44) vanishes.

To clarify the question of the normalization of the gravitational modes, we shall employ the following technique. The equation of motion (46) can be obtained with the help of the action

$$S^{(2)} = \int d^4 x \sqrt{-g^{(0)}} h_{\mu\nu} K_{\mu\nu}^{(0)} h_{\lambda\rho}$$

Hence follows the canonically-conjugate momentum for the field $h_{\mu\nu}$ and the simultaneous commutation relations:

$$\pi^{\mu\nu} = \sqrt{-g^{(0)}} \nabla^{(0)} h_{\mu\nu}$$

$$[h_{\mu\nu}(x), \pi^{\lambda\rho}(y)] = i \delta^{(3)}(x-y) \delta_{(\mu}^{\lambda} \delta_{\nu)}^{\rho}$$

Evidently, in Eq. (50) the fields are free of constraints (48). Let’s represent the field $h_{\mu\nu}$ in the form (compare with the first term in Eq. (40))

$$h_{\mu\nu}(x) = \sum_N \left( h_{N,\mu\nu}(x) c_N + h_{N,\mu\nu}^*(x) c_N^{\dagger} \right) \quad (51)$$

The set of operators $\{c_N, c_N^{\dagger}\}$ form a Heisenberg algebra (1), and the functions $\{h_{N,\mu\nu}\}$ satisfy Eq. (46). Equations (50) and (51) lead to the following relations reflecting the orthonormal nature of the set of the modes:

$$i \int_{\Sigma^{(3)}} d^3 x \sqrt{-g^{(0)}} \left[ h_{M,\mu\nu}^{\ast} \nabla^{(0)} h_{N,\mu\nu} - (\nabla^{(0)} h_{M,\mu\nu}) h_{N,\mu\nu} \right] = \delta_{M,N} \quad (52)$$
In the latter equations the integration extends over any spacelike hypersurface $\Sigma^{(3)}$. As a result of Eqs. (46), integrals (52) indeed do not depend on the hypersurface. It is natural to assume that the gravitational modes satisfy conditions (52). The significance of Eqs. (52) is that the normalization of the coefficient functions in expansion (40) is given with its help.

In the second order in $l_P$, we obtain the following equations:

\[
\frac{1}{2} K^{(0)}_{\mu\nu} \lambda \rho h_{N_1 N_2} = -R^{(0)(2)}_{\mu\nu} \left( h_{N_1}, h_{N_2} \right), \tag{53}
\]

\[
\frac{1}{2} K^{(0)}_{\mu\nu} \lambda \rho h_{N_1 N_2} = -2 R^{(0)(2)}_{\mu\nu} \left( h_{N_1}, h_{N_2} \right), \tag{54}
\]

\[
\frac{1}{2} K^{(0)}_{\mu\nu} \lambda \rho h^{F(\pm)}_{N_1 N_2} = \pm \frac{i}{4} \left( \overline{\psi}^{(0)(\pm)}_{N_1} \gamma^e e^{(0)} c_{(\mu} D^{(0)}_{\nu)} \psi^{(0)(\pm)}_{N_2} - e^{(0)} c_{(\mu} D^{(0)}_{\nu)} \overline{\psi}^{(0)(\pm)}_{N_1} \gamma^e \psi^{(0)(\pm)}_{N_2} \right), \tag{55}
\]

\[
\frac{1}{2} K^{(0)}_{\mu\nu} \lambda \rho h^{F(+)}_{N_1 N_2} = \frac{i}{4} \left( \overline{\psi}^{(0)(+)}_{N_1} \gamma^e e^{(0)} c_{(\mu} D^{(0)}_{\nu)} \psi^{(0)(-)}_{N_2} - e^{(0)} c_{(\mu} D^{(0)}_{\nu)} \overline{\psi}^{(0)(+)}_{N_1} \gamma^e \psi^{(0)(-)}_{N_2} \right), \tag{56}
\]

\[
\frac{1}{2} K^{(0)}_{\mu\nu} \gamma^e g^{(2)}_{(cl)} \lambda \rho = - \sum_{|N|<N_0} R^{(0)(2)}_{\mu\nu} \left( h_{N_1}, h_{N_2} \right) + \frac{i}{4} \sum_{|N|<N_0} \left( \overline{\psi}^{(0)(-)}_{N} \gamma^e e^{(0)} c_{(\mu} D^{(0)}_{\nu)} \psi^{(0)(-)}_{N} - e^{(0)} c_{(\mu} D^{(0)}_{\nu)} \overline{\psi}^{(0)(-)}_{N} \gamma^e \psi^{(0)(-)}_{N} \right). \tag{57}
\]

It is evident from Eq. (29) that torsion appears in the same order $\sim l_P^2$. Here, however, we do not write out the corresponding corrections for the connection.

We shall now briefly summarize the results obtained.

According to the dynamic quantization method, the quantization of gravity starts with finding a solution of the classical microscopic field equations of motion (for example, the solution of Eqs. (42) in the example considered above). The classical solution is determined by (or determines) the topology of space-time. Then, using the classical approach, Eqs. (43) and (46), which determine the single-particle modes $\{ \psi^{(\pm)}_N, h_{N\mu\nu} \}$, are solved. To solve Eq. (46) the gauge must be fixed, since the operator (44) is degenerate because of the gauge invariance of the theory. At the first step these modes are determined in the zeroth approximation according to the Planck scale, and their normalization is fixed using Eqs. (39) and (52). Given the set of modes $\{ \psi^{(0)(\pm)}_N, h_{N\mu\nu} \}$, we can explicitly write out the right-hand sides of Eqs. (53)-(57) and then solve them for the two-particle modes $h_{N_1 N_2 \mu\nu}, h_{N_1 |N_2 \mu\nu}$, and so on, and find the correction $g^{(2)}_{(cl)\mu\nu}$ which is of second order in $l_P$ to the classical component of the metric tensor. We call attention to the fact that the right-hand side of Eq. (57) arises because the operators must be normal-ordered. The solution of Eq. (57) can be interpreted as a single-loop contribution to the average of the metric tensor with respect to the ground state.

We note that if a nonsymmetric bilinear form were used on the right-hand sides of Eqs. (53)-(57), then the condition that the metric tensor be real would be violated. Consequently, the condition that the metric tensor is real determines the ordering of the
operator fields in the equations of motion at least in second order with respect to the operator fields.

It is important that all Eqs. (42), (46), and so on which arise are generally covariant, since they are expansions of generally covariant equations. Thus, the dynamic quantization method leads to a regularized gauge-invariant theory of gravity, which contains an arbitrary number of physical degrees of freedom.

We shall now make a remark about the compatibility of Eqs. (53)-(57) and the analogous equations arising in higher orders. Let $h_{\mu\nu}$ be an arbitrary symmetric tensor field and $K^{(0)}$ the operator (44), acting on this tensor field. It is easily verified that, using Eqs. (42), we obtain the identity (compare with Eq. (48))

$$\nabla^{(0)}_{\nu}(K^{(0)}h)^{\nu}_{\mu} - \frac{1}{2}\nabla^{(0)}_{\mu}(K^{(0)}h)^{\nu}_{\nu} = 0. \tag{58}$$

Consequently, in order for Eqs. (53)-(57) to be compatible the right-hand sides of these equations must satisfy the same identity. It is easy to see that this is indeed the case in lowest order. Indeed, Eqs. (53)-(56) are identical to the analogous classical equations arising when nonuniform modes (higher order harmonics) and the subsequent expansion of the classical Einstein equation in powers of the nonlinearity or the Planck length are added to the uniform fields. Hence it follows that each term on the right-hand sides of the "loop" equations of the type (57) likewise satisfy the necessary identity, since these terms have the same form as the right-hand sides of the "nonloop" Eqs. (53)-(56).

In highest orders in creation and annihilation operators the compatibility of arising equations follows from the gauge invariance of the regularized Einstein equation. Indeed, the identity (58) is the consequence of gauge invariance (invariance relative to the general coordinate transformations) of the equation. To clarify the question let’s rewrite the action (28) (for simplicity with $m = 0$, $\Lambda = 0$) in the following form:

$$S = S_g + S_\psi, \tag{59}$$

$$S_g = -\frac{1}{4l^2_P} \int d^4x \varepsilon_{abcd}\varepsilon^{\mu\nu\lambda\rho}e^a_{\mu}R^{bc}_{\nu\lambda}e^d_{\rho}, \tag{59a}$$

$$S_\psi = \frac{1}{6} \int d^4x \varepsilon_{abcd}\varepsilon^{\mu\nu\lambda\rho}\left[\frac{i}{2}\psi e^b_{\nu}e^c_{\rho}\gamma^a D_\mu\psi + h.c.\right] \equiv \int d^4x \bar{\psi} \overleftrightarrow{\mathcal{D}} \psi. \tag{59b}$$

Here $\overleftrightarrow{\mathcal{D}}$ is Dirac hermitian operator, depending on other operator fields. The Heisenberg–Dirac equations are written in the form

$$\overleftrightarrow{\mathcal{D}} \psi = 0, \quad \bar{\psi} \overleftrightarrow{\mathcal{D}} = 0. \tag{60}$$

In Eqs. (60) the disposition of creation and annihilation operators is the same as in the action (59). Einstein equation is the condition of stationarity of the action (59) relative to variations of metric or tetrad. Evidently, the action (59) is invariant under the general coordinate transformation even if the fields are quantized. This follows from the facts that under the coordinate transformations all fundamental fields transform linearly and that the action (59) is a polynomial relative to the fundamental fields. Therefore, if the material fields are on mass shell (in our case this means that Eqs. (60) hold), the action (59) is stationary under infinitesimal gauge transformation of tetrad field only. This means that the quantum energy-momentum tensor on mass shell satisfies to some
identity which in classical limit transforms to the well known identity $T^\mu_{\nu\mu} = 0$. From this quantum identity it follows that if some quantum tetrad field satisfies Einstein equation, then the field transformed by infinitesimal gauge transformation also satisfies Einstein equation. From here the compatibility of quantum Einstein equation follows, as well as the compatibility of the chain of equations described above. However, this conclusion is true only if quantum Dirac equations (60) hold, and the operators in the action and energy-momentum tensor are placed so as in Eq. (59). In other words, the creation and annihilation operators in Eqs. (59) and (60) must be placed identically. This is the guarantee of self-consistency of the chain of equations arising from exact quantum Einstein and motion equations.

We also call attention to the fact that in the dynamic quantization method it is implicitly assumed that the quantum anomaly is absent in the algebra of the first class constraints operators. Consequently, the dynamic quantization method must be justified in each specific case by concrete calculations, which must be not only mathematically correct but also physically meaningful.

4. The possible solution of cosmological constant problem

It follows from Eqs. (43) that in lowest order the Dirac field

$$\psi^{(1)}(x) = \sum_{|N|<N_0} \left( a_N \psi_N^{(0)(+)}(x) + b_N^{\dagger} \psi_N^{(0)(-)}(x) \right)$$

(61)

satisfies the Dirac equation

$$(ie^{(0)}_a \gamma^a D^{(0)} - m)\psi^{(1)}(x) = 0.$$  \hspace{1cm} (62)

Here $D^{(0)}_\mu$ is the covariant derivative operator in zeroth order:

$$D^{(0)}_\mu = \partial/\partial x^\mu + (1/2)\omega^{(0)}_{ab\mu} \sigma^{ab} + ieA^{(0)}_\mu,$$  \hspace{1cm} (63)

and $A_\mu$ is the gauge field.

It follows from Eq. (62) that the charge

$$Q = \int d^3x \sqrt{-g^{(0)}} e^{a(0)}_a (\bar{\psi}^{(1)} \gamma^a \psi^{(1)}).$$

(64)

conserves (compare with (39)).

According to (33) the contribution of the Dirac field to the energy-momentum tensor in lowest order is equal to

$$T^{(2)}_{\psi\mu\nu} = \text{Re} \left[ \bar{\psi}^{(1)} \gamma^a e^{(0)}_a D^{(0)}_{\nu} \psi^{(1)} \right].$$

(65)

Using Eqs. (36) it is easy to find vacuum expectation value of the quantity (65):

$$\langle T^{(2)}_{\psi\mu\nu} \rangle_0 = \text{Re} \left[ i \sum_{|N|<N_0} \bar{\psi}^{(0)(-)}_N \gamma^a e^{(0)}_a D^{(0)}_{\nu} \psi^{(0)(-)}_N \right].$$

(66)
Now let us take into account that the scenario described by the inflation theory is realized in Universe. It follows from here in conjunction with the used quantization method that in zeroth approximation the metric is expressed as

\[ ds^{(0)}^2 = dt^2 - a^2(t) \, d\Omega^2, \]  

(67)

where \( d\Omega^2 \) is the metric on unite sphere \( S^3 \), and \( a(t) \) is the scale factor of Universe at the running moment of time \( t \). It follows from (67) that \( \epsilon_a^{(0)} = \delta_a^0 \) and \( \sqrt{-g^{(0)}} \, d^3 x = dV^{(0)}(t) \), where \( dV^{(0)}(t) \) is the volume element of 3-space in the running moment of time. From conservation of operator (54) the conservation of the set of integrals

\[ \int dV^{(0)}(t) \, \psi_N^{(0)(\pm)} \psi_M^{(0)(\pm)} = \delta_{NM}. \]  

(68)

follows. The equality to unity of integrals (68) means that the wave functions \( \psi_M^{(0)(\pm)} \) are normalized relative to the volume of all Universe, so that the charge operator has the form

\[ Q = \sum_{|N|<N_0} (a_N^\dagger a_N + b_N b_N^\dagger). \]  

(69)

The idea how the vacuum expectation value of the matter energy-momentum tensor becomes enough small at present is demonstrated by the following estimation.

According to (68) we have:

\[ \left| \bar{\psi}_{N}^{(0)(\pm)} \psi_{N}^{(0)(\pm)} \right| \sim \frac{1}{a^3(t)}. \]  

(70)

Therefore the estimation for the value (66) is the following:

\[ \langle T_{\psi,\mu\nu}^{(2)} \rangle_0 \sim \frac{N_0 k_{\text{max}}}{a^3(t)}, \]  

(71)

where \( k_{\text{max}} \) is the value of the order of maximal momentum of the modes \( \{\psi_N^{(0)(\pm)}\} \). It is naturally to suppose that

\[ k_{\text{max}} \sim l_P^{-1} \sim G^{-1/2} \sim 10^{33} \text{ cm}^{-1}. \]  

(72)

Since the numerator in the right hand side of relation (71) is finite and the denominator is proportional to the volume of Universe which swells up approximately \( 10^{100} \) times more according to inflation scenario, the quantity (71) can be found enough small at present.

On the other hand, it is seen from the estimation (71) that at early stages of Universe evolution the quantum fluctuations played decisive role because the scale of the Universe were small.

One should pay the attention to the fact that the dynamics of the system creates two opposite tendencies for mode frequencies changing.

According to the first tendency the frequencies \( \omega \) of all one-particles modes change in time according to the low

\[ \omega \sim \frac{1}{a(t)}. \]  

(73)

The low (73) is valid in relativistic case. So, all frequencies decrees with expansion of Universe.
Now let us write out the first items of formal solution of Dirac equation (32) or (60) neglecting gravity degrees of freedom (i.e. in the case of flat space-time) but in the presence of gauge field:

\[ \psi(x) = \psi^{(1)}(x) + e \int d^4 y S_{\text{ret}}(x - y) A^{(1)}_{\mu}(y) \gamma^\mu \psi^{(1)}(y) + \]

\[ + 4\pi e^2 \int \frac{d^4 y d^4 z}{2 \pi} \mathcal{S}_{\text{ret}}(x - y - z) \left( \bar{\psi}^{(1)}(z) \gamma^\mu \psi^{(1)}(z) \right) \gamma^\mu \psi^{(1)}(y) + \ldots , \]  

(74)

\[ (i\gamma^\mu \partial_\mu - m) S_{\text{ret}}(x) = \delta^{(4)}(x), \]  

(75)

\[ \partial_\mu \partial^\mu D_{\text{ret}}(x) = \delta^{(4)}(x). \]  

(76)

Here \( S_{\text{ret}}(x) \) and \( D_{\text{ret}}(x) \) are the retarded Green functions satisfying Eqs. (75) and (76). It is seen from the solution (74) that the exact field \( \psi(x) \) have much more nonzero Fourier components than the field \( \psi^{(1)} \). Hence, the exact solution of quantum Dirac equation has all Fourier components only with finite momenta. From here we see the opposite dynamic tendency: the frequencies of modes effectively increases as a consequence of interaction. If the fact of strict conservation of the charge is taken into account, the conclusion about noncompact "packing" of modes in momentum space should be made. Indeed, let’s calculate the mean value of charge operator relative to a state \( |\rangle \). We have:

\[ \int d^3 x \langle \psi^\dagger(x) \psi(x) |\rangle = \int \frac{d^3 k}{(2 \pi)^3} \langle \psi^\dagger_k \psi_k |\rangle = \text{const} , \]

\[ \psi_k |\rangle = \int d^3 x e^{-ikx} \psi(x) . \]

The last relation means also that the integral

\[ \int d^3 x \text{tr} \langle \psi(x) \psi^\dagger(y) |\rangle \gamma^0 , \]

\[ y \rightarrow x , \quad y^0 > x^0 \]

constructed with the help of correlator \( \langle \psi(x) \psi^\dagger(y) |\rangle \) is conserved in time. But the mean value of energy-momentum tensor is constructed with the help of the same correlator. From here it is seen the effect of "loosening of mode packing" in momentum space. This effect is absent in the theory with dense packing of modes in all diapason of momenta since all states in momentum space are filled by the corresponding modes.

To solve the problem of "loosening of mode packing" in momentum space one must solve quantum kinetic equation for state density in momentum space. This problem is not solved in this work. But the fact of noncompact "packing" of modes in momentum space plays an important role in our consideration. Thus, the noncompact "packing" of modes in momentum space is taken here as an assumption.

At a dense "packing" of modes in momentum space the neighbouring momenta differ by the quantity of the order of \( \Delta k_{\text{min}} \sim 1/a(t) \). Therefore

\[ dN \sim \frac{a^3(t) d^3 k}{(2 \pi)^3} . \]  

(77)

\footnote{It means strict conservation of quantum charge operator which in lowest order transforms into expression (64).}
At noncompact "packing" of modes in momentum space the neighbouring momenta differ by the greater quantity. Assume that at small momenta this difference at present is of the order of $\Delta k_{\min} \sim 1/\lambda_{\text{max}}$. Furthermore, we shall use Lorentz-invariant measure in momentum space $[d^3 k/|k|]$. Thus we obtain instead of (77) the following estimation for the total number of physical degrees of freedom:

$$ N_0 \sim \lambda_{\text{max}}^3 \int k_{\text{max}}^3 \frac{d^3 k}{(2\pi)^3 |k|} \sim (\lambda_{\text{max}} k_{\text{max}})^2. \quad (78) $$

Now using (71) and (78) we find:

$$ 16\pi G \langle T_{\mu\nu} \rangle_0 \sim \frac{l_P^2 \lambda_{\text{max}}^2 k_{\text{max}}^3}{a^3(t)} \leq \Lambda; \quad (79) $$

and from here

$$ a(t_0) \geq \frac{(l_P \lambda_{\text{max}})^{2/3} k_{\text{max}}}{\Lambda^{1/3}}. \quad (80) $$

If one assume that

$$ \lambda_{\text{max}} \sim 10^{24}\text{cm} \sim 10^{-4}L, \quad (81) $$

where $L = 10^{28}\text{cm}$ (the dimension of observed part of Universe), then with the help of relations (2), (4), (81) and (80) we find the following estimation for the present dimension of Universe:

$$ a(t_0) \geq 10^{17}L. \quad (82) $$

At obtaining the estimation (82) it was assumed that the fundamental field theory is not supersymmetric. If one assume that the fundamental theory is supersymmetric, but the spontaneous breaking of supersymmetry occurs on the momentum $\sim k_{\text{SS}}$, then the estimation of the dimension of Universe is changed. Indeed, in this case instead of (72) we have

$$ k_{\text{max}} \sim k_{\text{SS}}, \quad (83) $$

since according to (9) and (10) the boson and fermion contributions to the vacuum expectation value of energy-momentum tensor with momenta greater than $k_{\text{SS}}$ are mutually cancelled. Therefore instead of (80) we obtain:

$$ a(t_0) \geq \frac{(l_P \lambda_{\text{max}})^{2/3} k_{\text{SS}}}{\Lambda^{1/3}} \sim 10^{29}\text{cm} \sim 10L. \quad (84) $$

At obtaining the numerical estimation of right hand side Eq. (84) we used assumptions (81) and the popular assumption in particle physics that $k_{\text{SS}} \sim 10^3\text{GeV} \sim 10^{17}\text{cm}^{-1}$.

The inclusion of quantum fluctuations of others fields into our estimations does not changes the result. This is clear already from dimensional considerations.

The inclusion of higher order corrections by perturbation theory also does not changes the obtained estimations. Indeed, all known fundamental interactions except for gravitational are renormalizable and thus can be considered by perturbation theory without changing fundamental properties of the vacuum. But the gravitational quantum corrections are obtained by expanding in Planck scale $l_P$. Again from dimensional considerations it is clear that such corrections at passing to the following order in our theory have the comparative value

$$ \sim \left(\frac{l_P}{a(t_0)}\right)^2 N_0 \sim \left(\frac{l_P}{a(t_0)}\right)^2 (\lambda_{\text{max}} k_{\text{max}})^2 \leq \left(\frac{\lambda_{\text{max}}}{a(t_0)}\right)^2 \ll 1. \quad (85) $$
5. Discussion

Does the Casimir effect survives in proposed theory? The answer to this question is positive. Indeed, the attraction force between plates of condenser which is caused by Casimir effect is the derivative of sum of photon zero-point energies with respect to distance between plates. But only modes with wavelength commensurable with the distance between plates \( d \) really give the contribution in this derivative. And since \( d \ll \lambda_{\text{max}} \) the distortion of Casimir effect does not occurs.

One should pay attention to the fact that in presented theory with noncompact packing of modes the gravitational and gauge interaction forces does not become weaker. It is seen from quantum equations of motion which have the canonical form with usual interaction constants. Thus the interaction between any modes has the usual strength.

Further, one can assume that in considered theory the stochastization of phases of modes takes place on distances less than \( \lambda_{\text{max}} \). Under the phase stochastization we mean that any correlation between phases of wave packets spaced by an enough distance can not take place. Such stochastization must occur if considered theory is the long-wavelength limit of discrete quantum theory of gravity discussed in [12]. The point is that in long-wavelength limit the lattice action \( S \) transforms to the action which is expressed as follows:

\[
S = S_{\text{Einstein}} + \Delta S.
\]

Here \( S_{\text{Einstein}} \) is standard Einstein action which does not retains any information about the structure of lattice, and \( \Delta S \) depends only on higher derivatives of the fields and also it essentially depends on the structure of the lattice. Therefore equations of motion contain the items with higher derivatives of fields and casual coefficients depending on structure of irregular lattice (simplicial complex). These items play negligible part for low frequencies modes but their part increase with increasing of mode frequency. The items with higher derivatives of fields and casual coefficients lead to diffusional propagation of modes and so to stochastization of phase on large distances. But just due to this circumstance the high frequency wave packets can be localized in relatively small regions of space. This means that noncompact "packing" of modes in momentum space does not affects to the possibility of localization of high frequency wave packets.

Let’s consider, for example, the system of finite number of electrons and positrons with wavelengths much less than \( \lambda_{\text{max}} \). Assume that we are interested in the usual problem of particle physics: the scattering matrix problem. The dynamics of real relativistic particles is described by the usual Dirac and Maxwell equations. The dynamic process of particles localized in finite space volume \( v \ll \lambda_{\text{max}}^3 \) is studied. Since the matrix elements between localized states and nonlocalized states tends to zero as \( a^{-3/2}(t_0) \), so only matrix elements between localized states are significant in the studied problem. This conclusion is true also with respect to virtual modes. From here it follows that for description of processes proceeding in finite volume of space \( v \), one must use the renormalized quantum fields \( (\psi_r, \ldots) \) which are normalized to the volume \( v \). This means that the wave functions of the states \( \{\psi_{r,N}(x), \ldots\} \) which create and annihilate the renormalized fields are normalized to the volume \( v \), these wave functions form the complete set of one particle wave functions with confined energies, and the corresponding creation and annihilation operators satisfy to standard relations (36). Note that the quantization conditions (36), i.e. nullification
of ground state by annihilation operators, follow from the fact that the causal correlators 
\[ \langle 0 | T \psi(x) \overline{\psi(y)} | 0 \rangle \]
describe propagation only positive-frequency waves. It seems that more general and correct definition of ground state \( |0\rangle \) instead of definition (26) or (36) is that the amplitudes
\[ \langle 0 | T \psi(x) \overline{\psi(y)} | 0 \rangle, \quad \langle 0 | T A_i(x) A_j(y) | 0 \rangle, \ldots \] (86)
describe the propagation of only positive-frequency waves if the times \( x^0 \) and \( y^0 \) are close to some time moment \( t_0 \). At present the state of Universe is close to the ground state. One can say that the renormalized fields \((\psi_r, \ldots)\) are the secondary quantized fields with the complete (at confined energies) and normalized on volume \( v \) set of one-particle states \( \{ \psi_{rN}(x), \ldots \} \). Thus the cosmological fields \((\psi, \ldots)\) from which quantum global Einstein equation is composed and the secondary quantized fields \((\psi_r, \ldots)\) are different though they describe the particles with the same quantum numbers. The causal correlators constructed from renormalized fields \( \psi_r \) (renormalized correlators) and thus describing local interactions also satisfy the conditions (86). Since local states normalized to volume \( v \) have compact "packing" in momentum space (at least for experimentally tested momenta), the renormalized correlators satisfy the standard equations:
\[ (i\gamma^\mu \partial_\mu - m) \langle 0 | T \psi(x) \overline{\psi(y)} | 0 \rangle = i \delta^4(x - y), \ldots, \]
which are true at \( |x^0 - y^0| \gg l_P, \ |x - y| \gg l_P. \) And since the calculations of \( S \)-matrix elements are performed by using the standard Dirac and Maxwell equations with usual value of charge and others parameters, as a result the usual expressions for \( S \)-matrix elements are obtained.

Let’s emphasize that at solving cosmological problems the retarded Green functions are used but at calculating \( S \)-matrix elements the causal or Feynman one are used.

We make the last remark about violation of Lorentz invariance in the theory. Since as a matter of fact the regularization is performed here by energy but not Lorentz invariant square of 4-momentum, so Lorentz invariance can be violated. However, until the processes with low energies (in comparison with the cutoff energy) are studied the violation of Lorentz invariance is negligible. The regularization by energy of calculations in QED is used, for example, in \[13\], and at the same time Lorentz invariance is not violated at low energies. Therefore the fact that all observed phenomena in nature are Lorentz covariant does not contradicts to the proposed theory since these phenomena has been observed at confined energies.

Despite many remaining unclear questions, it seems to us that presented here ideas worth to be discussed.

ACKNOWLEDGMENT
I thank participants of seminar of prof. A. A. Belavin for useful discussion, and especially prof. B. G. Zakharov. This work was supported by the Program for Support of Leading Scientific Schools \# 2044.2003.2. and RFBR \# 04-02-16970-a.

Appendix
For clearness it is useful to see the phenomenon of imposing the second class constraints without changing of quantum field equations on an example of free Klein–Gordon theory. The Klein–Gordon fields are expanded as follows:

\[
\phi(x) = \sum_k \frac{1}{\sqrt{2\omega_k}} \left( a_k \phi_k(x) + a^\dagger_k \phi_k^*(x) \right),
\]

\[
\pi(x) = -i \sum_k \sqrt{\frac{\omega_k}{2}} \left( a_k \phi_k(x) - a^\dagger_k \phi_k^*(x) \right),
\]

\[
\omega_k = \sqrt{k^2 + m^2}, \quad [a_k, a^\dagger_p] = \delta_{kp}.
\]

(A1)

Here \(\{\phi_k(x)\}\) is the complete set of orthonormal functions, so that

\[
\sum_k \phi_k(x) \phi_k^*(y) \bigg|_{x^0 = y^0} = \delta^{(3)}(x - y),
\]

\[
\Delta \phi_k(x) = -k^2 \phi_k(x).
\]

(A2)

The Hamiltonian

\[
\mathcal{H} = \int d^3 x \left( \frac{1}{2} \pi^2 + \frac{1}{2} \nabla \phi \nabla \phi + \frac{m^2}{2} \phi^2 \right) = \frac{1}{2} \sum_k \omega_k \left( a_k a^\dagger_k + a^\dagger_k a_k \right).
\]

(A3)

Equations of motions are obtained with the help of Eqs. (A1)-(A3):

\[
\dot{\phi}(x) = -i[\phi(x), \mathcal{H}] = -i \sqrt{\frac{\omega_k}{2}} \left( a_k \phi_k(x) - a^\dagger_k \phi_k^*(x) \right) = \pi(x),
\]

\[
\ddot{\phi}(x) = \ddot{\pi}(x) = -i[\pi(x), \mathcal{H}] =
\]

\[
= - \sum_k \frac{\omega_k^2}{\sqrt{2\omega_k}} \left( a_k \phi_k(x) + a^\dagger_k \phi_k^*(x) \right) = (\Delta - m^2) \phi(x).
\]

(A4)

Now let us impose any number of pairs of second class constraints

\[
a_{k_i} = 0, \quad a_{k_i}^\dagger = 0, \quad i = 1, 2, \ldots.
\]

(A5)

Then the sums \(\sum_k\) in (A1), (A3) and (A4) transform to the reduced sums \(\sum_{k \neq k_i}\). Nevertheless equation of motion (A4) retains its canonical form

\[
\left( \frac{\partial^2}{(\partial x^0)^2} - \Delta + m^2 \right) \phi(x) = 0.
\]

(A5)

The dynamical reason for this conclusion in considered example is that the commutators of the constraints (A5) with Hamiltonian are proportional to the constraints, i.e. they are equal to zero in a weak sense:

\[
[a_{k_i}, \mathcal{H}] = \omega_{k_i} a_{k_i}, \quad [a_{k_i}^\dagger, \mathcal{H}] = -\omega_{k_i} a_{k_i}^\dagger.
\]

(A7)

Therefore, as it was shown in Section 2, equations of motion in reduced theory must retain their canonical form.
