CONFORMAL HOLonomy OF BI-INVARIANT METRICS

FELIPE LEITNER

Abstract. We discuss in this paper the conformal geometry of bi-invariant metrics on compact semisimple Lie groups. For this purpose we develop a conformal Cartan calculus adapted to this problem. In particular, we derive an explicit formula for the holonomy algebra of the normal conformal Cartan connection of a bi-invariant metric. As an example, we apply this calculus to the group SO(4). Its conformal holonomy group is calculated to be SO(7).

1. Introduction

In Riemannian geometry the concept of holonomy is a well studied problem. The holonomy groups arise from affine connections on Riemannian manifolds. Most famous is the holonomy theory of the Levi-Civita connection, which is the canonical connection to a Riemannian metric. A list of possible holonomy groups in this case was first established in [Ber55].

In conformal geometry, there exists no canonical affine connection. Any choice of a torsion-free affine connection preserving the structure group (Weyl connection) is an additional datum to the conformal structure on a manifold. However, taking into consideration that conformal geometry should be understood as a 'second order' structure, it turns out and is a well-known fact that there exists a canonical Cartan connection on the prolonged principal fibre bundle of second order, which has a parabolic of the Möbius group as structure group. This canonical connection solves Cartan’s equivalence problem for conformal geometry, which says that two conformal structures are equivalent if and only if the canonical connections coincide. The canonical connection on a conformal space takes in general values in the Lie algebra $\mathfrak{so}(1, n + 1)$ of the Möbius group SO$(1, n + 1)$. As in the case of Riemannian geometry, the knowledge of the holonomy algebra and group defined to this canonical conformal Cartan connection is a significant invariant of a space with conformal structure. In particular, it describes invariant structures and solutions of invariant differential operators on a conformal space.

The aim of this paper is to develop and apply a conformal Cartan calculus to a very simple situation, namely the conformal geometry of bi-invariant metrics.

References
on compact semisimple Lie groups, in order to calculate the conformal holonomy explicitly. We proceed as follows. In the next two paragraphs, we recall briefly the basic concept of conformal Cartan geometry, in general, and the well-known notion of bi-invariant metrics. In paragraph 4, we develop the conformal Cartan calculus on bi-invariant metrics. In particular, we will describe the canonical connection and its curvature on a semisimple group $N$ by certain maps $\gamma_{nor}$ and $\kappa$, which live on the flat model $(\mathfrak{so}(1, n + 1), \mathfrak{p})$. Then we discuss properties of these maps and derive an explicit formula for the holonomy algebra (paragraph 5). Finally, we make explicit calculations for the bi-invariant metric on $SO(4)$, in particular, we derive the holonomy group.

It is the project of a forthcoming paper (cf. [Lei04b]) to investigate the conformal holonomy in more general situations e.g. like invariant metrics on (reductive) homogeneous Riemannian spaces. Even more generally, it is the idea to find explicit formulas and calculations for the holonomy of homogeneous parabolic geometries admitting a canonical Cartan connection (remember that conformal geometry is an example for a $[1]$-graded parabolic geometry). With homogeneous space we do not mean here a space with flat canonical connection, but a space with a parabolic geometry whose automorphism group acts transitively on the base space. Beside conformal geometry, a further classical example for this approach would be CR-geometry, which is a $[2]$-graded parabolic geometry.

2. Conformal Cartan geometry

We describe here briefly the conformal structure of a smooth manifold uniquely determined by a normal Cartan connection on a second order principal fibre bundle with parabolic structure group (cf. [Kob72], [CSS97]). We start with recalling the flat homogeneous model of conformal geometry.

Let $G = SO(1, n + 1)$ be the Lorentzian group, which acts on the $(n + 2)$-dimensional Minkowski space $\mathbb{R}^{1,n+1}$ equipped with the scalar product

$$(x, x)_{1,n+1} = 2x_0x_{n+1} + \sum_{i=1}^{n} x_i^2.$$ 

Its Lie algebra $\mathfrak{g} = \mathfrak{so}(1, n + 1)$ is $[1]$-graded by

$$\mathfrak{g} = \mathfrak{m}_{-1} \oplus \mathfrak{co}(n) \oplus \mathfrak{m}_1,$$

where $\mathfrak{m}_{-1} = \mathbb{R}^n$ and $\mathfrak{m}_1 = \mathbb{R}^{n*}$ are dual vector spaces via the Killing form on $\mathfrak{g}$. The $0$-part $\mathfrak{p}_0 := \mathfrak{co}(n)$ of this grading decomposes to the semisimple part $\mathfrak{so}(n)$ and the center $\mathbb{R}$, which is responsible for the conformal weight of a representation of $\mathfrak{g}$. In matrix form, we have

$$\begin{pmatrix} 0 & 0 & 0 \\ m & 0 & 0 \\ 0 & -t^{-1}m & 0 \end{pmatrix} \in \mathfrak{m}_{-1}, \quad \begin{pmatrix} -a & 0 & 0 \\ 0 & A & 0 \\ 0 & 0 & a \end{pmatrix} \in \mathfrak{p}_0, \quad \begin{pmatrix} 0 & l & 0 \\ 0 & 0 & -t^{-1}l \\ 0 & 0 & 0 \end{pmatrix} \in \mathfrak{m}_1.$$

The commutators are then given by

\[
\begin{array}{ll}
[A, A'] & = (AA' - A'A, 0) \\
[A, m] & = Am + am \\
[l, A] & = lA + al \\
[m, l] & = (ml - t^{-1}(ml), lm)
\end{array}
\]

where $(A, a), (A', a') \in \mathfrak{so} \oplus \mathbb{R}, m \in \mathbb{R}^n, l \in \mathbb{R}^{n*}$. The subalgebra

$$\mathfrak{p} := \mathfrak{co}(n) \oplus \mathfrak{m}_1$$

is parabolic, i.e., it contains a maximal solvable subalgebra of $\mathfrak{so}(1, n + 1)$.
Let $P$ be the closed subgroup of $G$ consisting of the matrices
\[
\left\{ \begin{array}{ccc}
a^{-1} & v & b \\
0 & A & r \\
0 & 0 & a \\
\end{array} \right| A \in SO(n), \ a \in \mathbb{R} \setminus 0, v \in \mathbb{R}^n, \\
r = -aA'v, \ b = -\frac{1}{2}(t^iv, iv)_n \end{array} \right\}.
\]
The group $P$ is the stabilizer of the point $o = [1 : 0 : \cdots : 0]$ in the projectivization $P_{n+1} \mathbb{R}$ of the Minkowski space $\mathbb{R}^{1,n+1}$ and the Lie algebra of $P$ is the parabolic $\mathfrak{p}$. The homogeneous space $G/P$ is the $n$-dimensional Möbius sphere $S^n$ with standard conformally flat structure, which is induced here from the scalar product on $\mathbb{R}^{1,n+1}$, and $G$ acts by conformal automorphisms on $S^n$. Furthermore, let $P_1$ be the closed subgroup of $P$ given by the matrices
\[
\left\{ \begin{array}{ccc}
1 & v & b \\
0 & I_n & -tv \\
0 & 0 & 1 \\
\end{array} \right| v \in \mathbb{R}^n, \ b = -\frac{1}{2}(t^iv, iv) \end{array} \right\}.
\]
This is the vector group $\exp \mathfrak{m}_1$ with Lie algebra $\mathfrak{m}_1$ and it is the kernel of the linear isotropy representation of $P$ acting on $T_o S^n$ (the point $o$ can be thought of as the point at infinity when conformally compactifying the Euclidean space $\mathbb{R}^n$). Since $P_1$ is normal, the quotient $P/P_1$ is a group itself, which is isomorphic to $CO(n)$. Any element $p \in P$ can be represented in a unique way by a product $p_0 \cdot \exp l$, where $p_0 \in CO(n)$ and $l \in \mathfrak{m}_1$.

The Maurer-Cartan form
\[
\omega_G : TG \to \mathfrak{g}
\]
is a Cartan connection on $S^n$ with parabolic structure group $P$. The Maurer-Cartan equation
\[
d\omega_G = -\frac{1}{2} [\omega_G, \omega_G]
\]
shows that the curvature of the Cartan connection $\omega_G$ vanishes, i.e., $\omega_G$ is a flat connection.

We apply now the flat model $(G, P)$ to (conformally) curved spaces. Let $(M^n, c)$ be a smooth manifold of dimension $n \geq 3$ with conformal structure $c$. The conformal structure $c$ is usually given as an equivalence class of metrics $[g]$, which differ from each other only by multiplication with a positive smooth function on $M$ (scaling function). The conformal structure $c$ defines a first order reduction $CO(M)$ of the general linear frame bundle $GL(M)$ to the structure group $CO(n)$ in the usual manner. On the other side, the conformal structure also induces a reduction $P(M)$ of the general linear frame bundle $GL^2(M)$ of second order to the structure group $P$. It is
\[
P(M)/P_1 \cong CO(M).
\]
Then the $CO(n)$-invariant lifts from $CO(M)$ to $P(M)$ are in 1-to-1 correspondence with Weyl connections on $(M, c)$, i.e., affine connections with structure group $CO(n)$ and without torsion.

The principal $P$-fibre bundle $P(M)$ admits a canonical Cartan connection $\omega_{nor}$, which, in particular, describes the embedding of $P(M)$ into $GL^2(M)$, and therefore determines the conformal structure $c$ on $M$. The canonical connection is made unique by imposing a normalisation condition. To say it in detail, the Cartan connection
\[
\omega_{nor} : TP(M) \to \mathfrak{g}
\]
has the properties:

1. $\omega_{nor}(p) : T_p P(M) \to \mathfrak{g}$ is an isomorphism for all $p \in P(M)$, which is along the fibre the tautological map, and
2. $R^*_p \omega_{nor} = Ad(p^{-1}) \omega_{nor}$, where $R^*_p$ denotes right translation by $p$ on $P(M)$. 

The curvature of $\omega_{nor}$ is defined by

$$K := d\omega_{nor} + \frac{1}{2}[\omega_{nor}, \omega_{nor}],$$

where

$$[\omega_{nor}, \omega_{nor}](X, Y) := [\omega_{nor}(X), \omega_{nor}(Y)] - [\omega_{nor}(Y), \omega_{nor}(X)]$$

for all $X, Y \in TP(M)$. It holds $R^p_wK = \text{Ad}(p^{-1})K$ and $K$ is in vertical direction trivial, i.e., inserting a vertical vector on $P(M)$ into $K$ produces zero. Alternatively, the curvature is uniquely determined by the function

$$\kappa = \kappa_{-1} \oplus \kappa_0 \oplus \kappa_1 : P(M) \to m^*_1 \otimes m^*_1 \otimes \mathfrak{g},$$

which is defined by

$$\kappa_p(a, b) = K_p(\omega_{nor}^{-1}(a), \omega_{nor}^{-1}(b))$$

for all $p \in P(M)$ and $a, b \in m_{-1}$. The normalisation condition, which makes the connection $\omega_{nor}$ unique, is expressed by the curvature properties

1. $\kappa_{-1} = 0$, i.e., the connection $\omega_{nor}$ is torsion-free, and
2. the trace-free condition $\text{tr} \kappa_0 = \sum_{i=1}^n \kappa_0(e_i, a)(b)(e^*_i) = 0$ for all $a, b \in m_{-1}$.

Thereby, the $e_i$'s denote the standard basis of $m_{-1} \cong \mathbb{R}^n$ and the $e^*_i$'s are dual in $m_1$.

The canonical normal Cartan connection and its curvature can be described with respect to a metric $g$ in the conformal class $c$ as follows. The metric $g$ determines a Weyl connection $\sigma_g$, i.e., an invariant lift from $\text{CO}(M)$ to $P(M)$. Then the pull-back $\sigma^*_g \omega_{-1}$ of the $(-1)$-part of $\omega_{nor}$ gives the soldering form on $\text{CO}(M)$, which in turn identifies (with respect to a base frame) the tangent space of $M$ at a point with $m_{-1}$. The $0$-part $\sigma^*_g \omega_0$ is the Levi-Civita connection form to $g$ on $\text{CO}(M)$ and $-\sigma^*_g \omega_1$ is tensorial and projects to $(M, g)$ as the Schouten tensor (‘rho’-tensor), which is defined by

$$L(X) = \frac{1}{n - 2} \left( \text{scal} \left( \frac{2}{n - 1} X - \text{Ric}(X) \right) \right),$$

where $\text{Ric}$ denotes the Ricci tensor and $\text{scal}$ the scalar curvature to $g$ on $M$. The (harmonic) $0$-part $K_0$ of the curvature of $\omega_{nor}$ corresponds to the Weyl tensor $W$ on $(M, g)$, which is the trace-free part of the Riemannian curvature tensor $R$, and can be expressed by

$$W := R - g \ast L,$$

where $g \ast L$ denotes a Kulkarni-Nomizu product. Finally, the negative $-K_1$ of the $1$-part of the curvature projects to the Cotton-York tensor $C$ on $(M, g)$, which is given in terms of $g$ by

$$C(X, Y) := \nabla_X^g L(Y) - \nabla_Y^g L(X).$$

3. Bi-invariant metrics

We recall here the notion of bi-invariant metrics on compact semisimple Lie groups. They will be the matter of our investigation when we apply in the next paragraph the Cartan calculus to their conformal classes.

Let $N$ be a connected and compact semisimple Lie group of dimension $n$ and let $\mathfrak{n}$ denote its Lie algebra. The Killing form

$$B(X, Y) := \text{tr} \text{ad}_X \text{ad}_Y$$

is $\text{Ad}(N)$-invariant and negative definite on $\mathfrak{n}$. In particular,

$$B(X, [Y, Z]) = B([X, Y], Z) \quad \text{for all } X, Y, Z \in \mathfrak{n}.$$
The negative $-B$ of the Killing form defines through left translation with the group multiplication an invariant metric $g_n$ on $N$. In fact, the metric $g_n$ is not only left-invariant, but also right-invariant under the group multiplication and the metric $g_n$ is called a bi-invariant metric on $N$ (cf. [O’N83]). In the following, we will often identify left-invariant vector fields on $N$ with their generators in $n$,

$$\tilde{X}(n) := \frac{d}{dt}\big|_{t=0} n \cdot \exp tX \quad \mapsto \quad X \in n.$$ 

For the Levi-Civita connection $\nabla$ of $g_n$, it holds

$$\nabla_X Y = \frac{1}{2} [X, Y] \quad \text{for all } X, Y \in n,$$

and the sectional curvature of a plane spanned by orthonormal elements $X, Y$ in $n$ is

$$S(X, Y) := -\frac{1}{4} B([X, Y], [X, Y]).$$

For the Ricci tensor we find

$$\text{Ric}|_n = -\frac{1}{4} B,$$

i.e., $\text{Ric} = \frac{1}{4} g_n$ and $g_n$ is an Einstein metric on $N$ with positive scalar curvature $\text{scal} = \frac{n}{4}$. The Schouten tensor is $L = -\frac{1}{8(n-1)} g_n$ and the Cotton-York tensor $C$ vanishes identically, $C \equiv 0$. For the Weyl tensor, we obtain

$$W = R + \frac{1}{8(n-1)} g_n \ast g_n.$$

4. Conformal Cartan geometry and bi-invariant metrics

At the end of the last paragraph we calculated already the content of the conformal curvature, the Weyl tensor and the Cotton-York tensor, in terms of the bi-invariant metric on a compact semisimple group. However, we want to establish here a conformal Cartan calculus for bi-invariant metrics. This will help us to get a better understanding of the normal connection and its curvature. Though, our approach will always use a convenient trivialisation, which represents the bi-invariant metric in the conformal class.

Let $N$ be a connected and compact semisimple Lie group of dimension $n$ with Lie algebra $n$ and bi-invariant metric $g_n$. Then there is the conformal structure $c_n = [g_n]$ defined on the group $N$. Let

$$\theta : (n, -B) \cong (m_{-1}, \langle \cdot, \cdot \rangle_n)$$

be an isometry and $(e_1, \ldots, e_n)$ the standard basis on $m_{-1} \cong \mathbb{R}^n$. The map $\theta$ transfers the Lie bracket $[\cdot, \cdot]_n$ to $m_{-1}$ through the expression

$$\rho_{n, \theta}(a, b) := \theta [\theta^{-1}(a), \theta^{-1}(b)]_n,$$

where $a, b \in m_{-1}$. (Likewise, we will also use the notation $[\cdot, \cdot]_n$ on $m_{-1}$). Moreover, the map $\theta$ induces the orthonormal frame

$$\{E_i := \theta^{-1}(e_i)| \quad i = 1, \ldots, n\}$$

on $n \cong T_e N$. The corresponding left-invariant frame field gives rise to a global trivialisation of the first order conformal frame bundle $CO(N)$ on $(N, e)$,

$$CO(N) \cong N \times CO(n)

\{\tilde{E}_i(s) \mid i = 1, \ldots, n\} \quad \mapsto \quad (s, e)$$
(in fact, it is a trivialisation of the orthonormal frame bundle of \((N, g_n)\)). We denote by \(P(N)\) the second order conformal frame bundle with parabolic structure group \(P\), which is a subbundle of \(GL^2(N)\). The bi-invariant metric \(g_n\) induces an invariant lift

\[ \sigma_{g_n} : CO(N) \to P(N) \]

and with the help of the \(\bar{E}_i\)'s also a trivialisation

\[ \iota_{\theta, g_n} : P(N) \cong N \times P \]

of the parabolic frame bundle. The left translation \(L_s : N \to N\) preserves for all \(s \in N\) the bi-invariant metric, hence the conformal structure \(c_n\). The translation \(L_s\) on \(N\) induces in a natural way transformations (also denoted by \(L_s\)) of the conformal frame bundles \(CO(N)\) and \(P(N)\). As we have chosen here the trivialisation \(\iota_{\theta, g_n}\), it holds

\[ \iota_{\theta, g_n} \circ L_s \circ \iota^{-1}_{\theta, g_n} : N \times P \to N \times P \]

\[ (n, p) \to (sn, p) \]

There exists a canonical Cartan connection on \(P(N)\) denoted by

\[ \omega_{nor} : TP(N) \to \mathfrak{g} \]

This connection is determined by its curvature properties, namely the curvature \(K\) is torsion-free and satisfies the trace-free condition on the 0-part \(K_0\) (cf. paragraph 2). By definition, the connection \(\omega_{nor}\) is right-invariant along the fibres, i.e.,

\[ R^*_{\theta} \omega_{nor} = \text{Ad}(\theta^{-1}) \omega_{nor} \quad \text{for all} \quad p \in P \]

and it is also left-invariant under the group multiplication on \(N\), i.e.,

\[ L^*_{s} \omega_{nor} = \omega_{nor} \]

The latter fact is, because, the normal Cartan connection is uniquely determined by the conformal structure and is therefore invariant under the conformal automorphism group. These two facts, the right-invariance by multiplication with \(P\) and the left-invariance with respect to \(N\), imply that \(\omega_{nor}\) on \(P(N)\) is uniquely determined by the (vector space) isomorphism induced from \(\omega_{nor}\) at a single point \(x_o\) of \(P(N)\). Using the trivialisation \(\iota_{\theta, g_n}\) from above, we can choose this point to \(x_o = (e, e)\) and then the isomorphism

\[ \omega_{nor}(e, e) : n \times p \to \mathfrak{g} \]

determines the canonical Cartan connection. Since the \((-1)\)-part of \(\omega_{nor}\) corresponds to the soldering form, it holds \(\omega_{-1}(e, e)(E_i) = e_i\). This leads us to the definition of the map \(\gamma_{nor}\) (which depends on the choice of \(\theta\)) through

\[ \gamma_{nor} : m_{-1} \to p \]

\[ a \mapsto \pi_p \circ \omega_{nor}(e, e) \circ \pi_n \circ \omega_{nor}^{-1}(e, e)(a) \]

where \(\pi_p\) and \(\pi_n\) denote the obvious projections (the latter with respect to our trivialisation). This map decomposes to

\[ \gamma_{nor} = \gamma_0 + \gamma_1 \]

and it still contains the whole information of the canonical Cartan connection \(\omega_{nor}\) on \(N\), since it holds the relation

\[ \omega_{nor}(E_i) = e_i + \gamma_{nor}(e_i) \]

In fact, \(\omega_{nor}\) is recovered from \(\gamma_{nor}\) by the latter relation, application of the trivialisation and translation from the left and right.
The curvature $K$ inherits the left- and right-invariance properties from the canonical connection $\omega _{\text{nor}}$ and $K$ is also determined by its values at the single point $(e, e)$ in $P \times N$. With respect to the trivialisation $t \in G$, we find that

$$E_i(\omega _{\text{nor}}(E_j))(e, e) = \frac{d}{dt}|_{t=0} \omega _{\text{nor}}(E_j)(\exp tE_i, e) = \frac{d}{dt}|_{t=0} L^*_e \omega _{\text{nor}}(E_j)(e, e)$$

for all $i, j = 1, \ldots , n$. This shows for the curvature the identity

$$K(E_i, E_j) = -\omega _{\text{nor}}(e, e)([E_i, E_j]_n) + [e_i + \gamma _{\text{nor}}(e_i), e_j + \gamma _{\text{nor}}(e_j)]_g .$$

The curvature function $\kappa$ of the canonical Cartan connection $\omega _{\text{nor}}$ can then be expressed by (recall that the curvature is vertically trivial)

$$\kappa (e_i, e_j) = -(id + \gamma _{\text{nor}}) \circ \rho _{n, \theta}(e_i, e_j) + [e_i + \gamma _{\text{nor}}(e_i), e_j + \gamma _{\text{nor}}(e_j)]_g .$$

Thereby, the $(-1)$-part of $\kappa$ is given through

$$\kappa _{(-1)}(e_i, e_j) = -\rho _{n, \theta}(e_i, e_j) + [e_i, \gamma _0(e_j)] + [\gamma _0(e_i), e_j] .$$

This expression vanishes, since $\omega _{\text{nor}}$ has no torsion. We see that the Lie bracket of $\mathfrak{n}$ is given on $\mathfrak{m}_{-1}$ by

$$\rho _{n, \theta}(e_i, e_j) = -\gamma _0(e_j) \cdot e_i + \gamma _0(e_i) \cdot e_j . \quad (1)$$

The $0$-part of $\kappa$ is

$$\kappa _0(e_i, e_j) = -\gamma _0 \circ \rho _{n, \theta}(e_i, e_j) + [e_i, \gamma _1(e_j)] + [\gamma _1(e_i), e_j] + [\gamma _0(e_i), \gamma _0(e_j)] .$$

This part satisfies the trace-free condition

$$\sum _{i=1} ^n \gamma _0 \circ \rho _{n, \theta}(e_i, a)(b)(e_i^*) = \left\{ \sum _{i=1} ^n [e_i, \gamma _1(a)](b)(e_i^*) + [\gamma _1(e_i), a](b)(e_i^*) \right\}$$

for all $a, b \in \mathfrak{m}_{-1}$. The $1$-part $\kappa _1$ of the curvature is

$$\kappa _1(e_i, e_j) = -\gamma _1 \circ \rho _{n, \theta}(e_i, e_j) + [\gamma _0(e_i), \gamma _1(e_j)] + [\gamma _1(e_i), \gamma _0(e_j)]$$

for all $i, j \in \{1, \ldots , n\}$. The linear map $\gamma _{\text{nor}} : \mathfrak{m}_{-1} \to \mathfrak{p}$ is uniquely determined be the normalisation conditions (1) and (2) with respect to $\rho _{n, \theta}$ (which depends on the choice of the frame $\theta$). (Otherwise, we would recover from another $\gamma$ which shares these properties a further normal connection, which is not possible.) So $\gamma _{\text{nor}}$ depends only on the choice of $\theta$ which induces the Lie bracket of $\mathfrak{n}$ on $\mathfrak{m}_{-1}$. We can introduce the following formal notions.

**Definition 1.** Let $(G, P)$ be the flat homogeneous model (of conformal geometry) and

$$\rho : \mathfrak{m}_{-1} \times \mathfrak{m}_{-1} \to \mathfrak{m}_{-1}$$

a skew-symmetric map, which satisfies the Jacobi identity and defines a Lie algebra bracket (of compact type) on the $(-1)$-part $\mathfrak{m}_{-1}$ of the grading of $\mathfrak{g}$.

1. We call a linear map

$$\gamma = \gamma _0 + \gamma _1 : \mathfrak{m}_{-1} \to \mathfrak{p}$$

(from the $(-1)$-part to the parabolic) a connection form on the model $(G, P)$.

2. The curvature

$$\kappa _{\gamma , \rho} = \kappa _{(-1)} + \kappa _0 + \kappa _1 : \mathfrak{m}_{-1} \times \mathfrak{m}_{-1} \to \mathfrak{g}$$

of the connection $\gamma$ with respect to the Lie bracket $\rho$ is defined as

$$\kappa _{\gamma , \rho}(a, b) = -(id + \gamma) \circ \rho(a, b) + [(id + \gamma)(a), (id + \gamma)(b)]_g$$

for $a, b \in \mathfrak{m}_{-1}$. 

(3) The connection $\gamma$ is called torsion-free with respect to $\rho$ if $\kappa_{-1} = 0$.

(4) The connection $\gamma$ is called normal with respect to $\rho$ if

$$\kappa_{-1} = 0 \quad \text{and} \quad \text{tr} \kappa_0 = 0$$

(cf. equation (3)).

(5) There exists a unique normal connection with respect to the bracket $\rho$. We denote it by $\gamma_\rho: m_{-1} \to p$ (or $\gamma_{nor}$ when the bracket is fixed on $m_{-1}$) and call it the canonical connection form of $\rho$ to the model $(G, P)$.

As we can see from formula (4), the Lie bracket of $\gamma_0$ of the normal connection $\gamma_{nor}$, since it has no torsion. In general, a skew-symmetric map

$$\gamma_0: m_{-1} \to p_0$$

defines a Lie bracket on $m_{-1}$ through

$$\rho_{\gamma_0}(a, b) = -\gamma_0(b) \cdot a + \gamma_0(a) \cdot b \quad \text{for all} \ a, b \in m_{-1}$$

if and only if the following sum of even permutations satisfies the relation (Jacobi identity)

$$\sum_{\sigma(i,j,k)} [\gamma_0[e_i, \gamma_0(e_j)] + \gamma_0[\gamma_0(e_i), e_j] - [\gamma_0(e_i), \gamma_0(e_j)], e_k] = 0$$

(3)

for all $i, j, k \in \{1, \ldots, n\}$. The map $\gamma_0$ can then be extended in an arbitrary manner to a torsion-free connection form $\gamma$ with respect to $\rho_{\gamma_0}$ just by adding any linear 1-part $\gamma_1$. In such a situation, the curvature function to $\gamma$ with respect to $\rho_{\gamma_0}$ is given by

$$\kappa_\gamma(e_i, e_j) = -\gamma_0([e_i, \gamma_0(e_j)] + [\gamma_0(e_i), e_j]) + [e_i, \gamma_1(e_j)] + [\gamma_1(e_i), e_j]$$

$$- [\gamma_0(e_i), \gamma_0(e_j)] - \gamma_1([e_i, \gamma_0(e_j)] + [\gamma_0(e_i), e_j] + [\gamma_0(e_i), \gamma_1(e_j)] + [\gamma_1(e_i), \gamma_0(e_j)].$$

Of course, not every torsion-free map $\gamma_0$ can be extended to the normal connection $\gamma_{nor}$ with respect to $\rho_{\gamma_0}$. The condition on $\gamma_0$ for being normally extendible is given by the existence of a $\gamma_1$ such that

$$\sum_{i=1}^n [\gamma_1(e_i) + [\gamma_1(e_i), a]](b)(e_i^*) = \begin{cases} \sum_{i=1}^n \gamma_0([e_i, \gamma_0(a)] + [\gamma_0(e_i), a])(b)(e_i^*) \\ - \sum_{i=1}^n [\gamma_0(e_i), \gamma_0(a)](b)(e_i^*) \end{cases}$$

(4)

for all $a, b \in m_{-1}$.

Finally, in this paragraph, we want to give explicit expressions for the maps $\gamma_0$ and $\gamma_1$ of the normal connection form $\gamma_{nor}$ and also for its curvature function $\kappa$ when $n$ is a semisimple Lie algebra (of compact type). The map $\gamma_0$ corresponds in this case to the Levi-Civita connection of the bi-invariant metric $g_n$ and is given with respect to a reference frame $\theta$ by

$$\gamma_0(e_i) = -\theta \circ \nabla_{\theta^{-1}(e_i)} E_i = \frac{1}{2} \rho_{\theta, \theta}(e_i, \cdot)$$

for all $i = 1, \ldots, n$. Obviously, the so-defined map $\gamma_0$, considered as a matrix in $p_0 = \mathfrak{a}(n)$ with respect to the basis $(e_1, \ldots, e_n)$, satisfies (1) (also (2)), i.e., $\gamma_0$ is torsion-free with respect to $\mathfrak{n}$ (and $\theta$). Then we calculate for the traces on the left hand side in (4):

$$\sum_{i=1}^n \gamma_0([e_i, \gamma_0(a)] + [\gamma_0(e_i), a])(b)(e_i^*) = \frac{1}{2} B_n(a, b) ,$$

$$\sum_{i=1}^n [\gamma_0(e_i), \gamma_0(a)](b)(e_i^*) = \frac{1}{4} B_n(a, b).$$

We set $\lambda = \frac{-1}{8(n-1)}$ and

$$\gamma_1(a) = \lambda a^*$$
for all $a \in m_{-1}$. Calculation of the right hand side in \[ (1) \]
gives
\[
\sum_{i=1}^{n}([e_i, \gamma_1(e_k)] + [\gamma_1(e_i), e_k])(e_l)(e_l^*) = 2\lambda(n - 1)\delta_{kl}
\]
for all $k, l \in \{1, \ldots, n\}$. Comparing both sides of (1) proves that the normal connection form for $n$ is determined to
\[
\gamma_{nor} : m_{-1} \rightarrow p.
\]
\[
a \mapsto \frac{1}{2}\rho_n\theta(a, \cdot) - \frac{1}{8(n-1)}a^*.
\]
The curvature functions $\kappa_{-1}$ and $\kappa_1$ vanish identically, since there is no torsion and the Cotton-York tensor $C$ of $g_n$ is trivial. The 0-part $\kappa_0$ is given by the Weyl tensor $W$ of $g_n$. It is
\[
\kappa(a, b) = \kappa_0(a, b) = \theta^*W(\theta^{-1}(a), \theta^{-1}(b)).
\]

5. Canonical Cartan Connection and Holonomy

In this paragraph, we conduct a further discussion of the connection form $\gamma_{nor}$. However, one should keep in mind that properties of $\gamma_{nor}$ depend on the choice of the trivialisation which comes from the bi-invariant metric, and therefore $\gamma_{nor}$ should be considered as a 'metric object'. Nevertheless, we will derive an explicit formula for its holonomy algebra, which is then a 'purely' conformal invariant.

Let
\[
\gamma_{nor} = \gamma_0 + \gamma_1 : m_{-1} \rightarrow p
\]
be the normal connection to some semisimple Lie algebra $n$ (of compact type) with induced bracket
\[
\rho_n = [\cdot, \cdot]_n
\]
on $m_{-1}$ (and with respect to $\sigma_{g_n}$ and some $\theta$). The first observation here is the following. One can show that the image of $m_{-1}$ under the 0-part $\gamma_0$ of $\gamma_{nor}$ is the Lie subalgebra $Der(n)$ in $p_0$ consisting of all derivations of $n \cong m_{-1}$. Since $n$ is semisimple, the Lie algebra $n$ itself is naturally isomorphic to $Der(n)$ by
\[
ad : n \rightarrow Der(n).
\]
\[
a \rightarrow ad_a.
\]
However, we will see that the map $\gamma_0 : m_{-1} \rightarrow p_0$ is not a Lie algebra isomorphism with respect to $\rho_n$ on $m_{-1}$. In detail, we can verify these statements as follows. Remember that the normal connection form to $n$ is given by
\[
\gamma_{nor}(a) = \frac{1}{2}\rho_n(a, \cdot) - \frac{1}{8(n-1)}a^*.
\]
With this expression in mind, it is obvious that the Jacobi identity in $n$ implies
\[
\gamma_0(x) \cdot [a, b]_n = [\gamma_0(x) \cdot a, b] + [a, \gamma_0(x) \cdot b]
\]
for all $x, a, b \in m_{-1}$, where the 'dot' denotes matrix multiplication of $p_0$ on $m_{-1}$. This shows that $\gamma_0(x)$ is a derivation on $n \cong (m_{-1}, \rho_n)$ for all $x \in m_{-1}$. Moreover, the kernel of $\gamma_0$ is trivial, since $\gamma_0(x) = 0$ implies that $x$ is in the center of $\rho_n$, which itself is trivial for semisimple $n$. We can conclude that $\gamma_0$ is a vector space isomorphism onto $Der(n)$ and, since $B_n([a, b]_n, b) = 0$ for $a, b \in n$, every derivation sits in the semisimple part $\mathfrak{so}(n)$ of $p_0$. In fact, the following statement is true.

Proposition 1. Let $n$ be a semisimple Lie algebra (of compact type) and $\gamma_{nor} = \gamma_n$ the corresponding connection form on the model $(g, p)$ (coming from $(G, P)$). Then the 0-part $\gamma_0$ of $\gamma_{nor}$ is with respect to $n$ the only torsion-free map, which sends $m_{-1}$ to the derivations $Der(n)$ sitting in $p_0$. 
Proof. As we have seen, the map $\gamma_0$ of $\gamma_{nor}$ admits the stated properties. We have to show that any other linear map $Q$ apart from $\gamma_0$ sending $m_{-1}$ to the derivations $\text{Der}(n)$ has torsion. This can be seen as follows. Since $Q$ is linear and $\gamma_0$ onto $\text{Der}(n)$, we can write $\gamma_0 - Q = \gamma_0 \circ A$ for some homomorphism $A$ on $m_{-1}$.

The map $Q$ has no torsion if and only if

$$-\gamma_0 \circ A(e_j)e_i + \gamma_0 \circ A(e_i)e_j = 0 \quad \text{for all } i, j.$$ 

Since $\gamma_0 \circ A(a) \in so(n)$ for all $a \in m_{-1}$, we find in the torsion-free case the relation

$$\gamma_0 \circ A(a) = 0 \quad \text{for all } a \in m_{-1}.$$ 

But this also implies

$$\gamma_0 \circ A(e_j)e_i + \gamma_0 \circ A(e_i)e_j = 0 \quad \text{for all } i, j,$$

which is only possible if $A = 0$, i.e., $Q = \gamma_0$.

Proposition 1 is a characterisation of the Levi-Civita connection to the bi-invariant metric. The stated criteria replace conditions (3) and (4) for a map $\gamma_0$ to be the 0-part of the normal connection $\gamma_{nor}$ for some semisimple $n$.

The 0-part $\kappa_0$ of the curvature function to $\gamma_{nor}$ of $n$ satisfies the relation

$$\kappa_0(a, b) - ([a, \gamma_1(b)] + [\gamma_1(a), b]) = -\gamma_0 \circ \rho_n(a, b) + [\gamma_0(a), \gamma_0(b)].$$

The expression on the left hand side of this equation is the Riemannian curvature tensor $R_{\gamma_0}$ for the bi-invariant metric $g_n$ in the conformal class $c_n$. Obviously, it measures the deviation of $\gamma_0$ from being a Lie algebra isomorphism onto $\text{Der}(n)$ sitting in $p_0$. Since the Riemannian curvature tensor of a semisimple Lie algebra is not zero, we can conclude that $\gamma_0$ is never a Lie algebra isomorphism. We state the following summary about the meaning of the curvature function $\kappa_{\gamma, n}$ of an (arbitrary) connection form $\gamma : m_{-1} \to p$ with respect to some semisimple Lie algebra $n$:

1. The $(-1)$-part $\kappa_{-1}$ of $\kappa_{\gamma, n}$ measures the deviation of the expression

$$-\gamma_0(b)a + \gamma_0(a)b, \quad a, b \in m_{-1}$$

from being a defining map for the Lie bracket of $n$ induced on $m_{-1}$.

2. The 0-part $\kappa_0$ is the deviation of the map $\gamma_0$ from being a Lie algebra homomorphism onto $\text{Der}(n)$ up to an expression depending on $\gamma_1$.

3. The 1-part $\kappa_1$ measures the deviation of the dual map

$$\gamma_1^* : m_{-1} \to m_{-1}$$

to $\gamma_1$ from being a derivation on $m_{-1} \cong n$.

4. In case that $\gamma = \gamma_n$ is the normal connection to $n$ there is no torsion and $\gamma_1$ is a derivation on $m_{-1}$. The part $\gamma_0$ always differs from a homomorphism onto $\text{Der}(n)$. The connection $\gamma_{nor}$ is flat, i.e., $\kappa = 0$, if and only if $n \cong su(2)$.

We come now to the second part of this paragraph concerning the holonomy of the canonical Cartan connection. Recall that the conformal automorphism group of a compact Riemannian space is always an isometry group with respect to some metric in the conformal class except in the case when the compact space is the sphere $S^n$ with canonical conformally flat structure (Möbius sphere). In particular, the conformal automorphism group of a compact semisimple Lie group with bi-invariant metric consists entirely of the right and left translations with respect to the group multiplication except for the case when $N = SU(2)$. However, the normal Cartan connection on a conformal space gives rise to another conformal invariant, which can be thought of as an expression for conformal symmetry on a space (and yet seems not to be naturally related to a particular metric in the conformal class), namely the holonomy group $Hol(\omega_{nor})$ of the canonical connection $\omega_{nor}$. To define this holonomy group, we use the natural extension of the normal Cartan connection.
\(\omega_{\text{nor}}\) on the parabolic frame bundle \(P(M)\) over a space \(M\) with conformal structure \(c\) to a usual principal fibre bundle connection \(\hat{\omega}_{\text{nor}}\) on the extended bundle

\[ G(M) = P(M) \times G \]

with structure group \(G = \text{SO}(1, n + 1)\).

**Definition 2.** Let \((M, c)\) be a space with conformal structure. The holonomy group \(\text{Hol}(\omega_{\text{nor}})\) of the canonical Cartan connection \(\omega_{\text{nor}}\) is defined to be the holonomy group of the naturally extended principal fibre bundle connection \(\hat{\omega}_{\text{nor}}\) on \(G(M)\), whose group elements arise in the usual way by parallel translation of a fibre in \(G(M)\) along closed curves on \(M\). The Lie algebra of \(\text{Hol}(\omega_{\text{nor}})\) is denoted by \(\mathfrak{hol}(\omega_{\text{nor}})\).

We remark that there is a direct way to define the holonomy group of a Cartan connection without using the extended bundle. However, this approach results in general to the same group as in our definition (cf. [Sha97]). Note also that the holonomy group \(\text{Hol}(\omega_{\text{nor}})\) is always a closed subgroup of the Möbius group \(G = \text{SO}(1, n + 1)\). We want to derive here a formula, which can be used for explicit calculations of the conformal holonomy on Lie groups with bi-invariant metric.

Let \(N\) be a connected and compact semisimple Lie group. Let \(\mathfrak{n}\) denote its Lie algebra with bi-invariant Riemannian metric \(g_n\). The canonical Cartan connection \(\omega_{\text{nor}}\) induces in a natural manner (with respect to the trivialisation coming from \(g_n\)) the map

\[ \gamma_{\text{nor}} : m_{-1} \cong \mathfrak{n} \to \mathfrak{p}, \]

which possesses all the informations of \(\omega_{\text{nor}}\) and, in fact, can be used to recover the canonical Cartan connection on \(P(N)\). We denote by

\[ \Lambda(m_{-1}) := \text{span}\{ (\text{id} + \gamma_{\text{nor}})(a) | a \in m_{-1} \} \subset g \]

the images of the normal connection and by

\[ \mathfrak{q} := \text{span}\{ \kappa_n(a, b) | a, b \in m_{-1} \} \subset \mathfrak{p} \]

the vector space of curvature values to the connection \(\gamma_{\text{nor}}\). There is a classical formula for the holonomy algebra of an invariant connection on a homogeneous space with arbitrary structure group \(G\) (cf. [KN63]). We use this result to derive here easily the following formula for the conformal holonomy algebra of a bi-invariant metric.

**Theorem 1.** (cf. [KN63]) Let \(N\) be a connected and compact semisimple Lie group with conformal structure \([g_n]\). Then the holonomy algebra of the normal Cartan connection \(\omega_{\text{nor}}\) on \((N, [g_n])\) is given by the expression

\[ \mathfrak{hol}(\omega_{\text{nor}}) := \mathfrak{q} + [\Lambda(n), \mathfrak{q}] + [\Lambda(n), [\Lambda(n), \mathfrak{q}]] + \cdots, \]

which is a subalgebra of \(\mathfrak{g} = \text{so}(1, n + 1)\). The reduced holonomy group \(\text{Hol}_{\text{red}}(\omega_{\text{nor}})\) is the connected subgroup of the identity component \(\text{SO}_+(1, n + 1)\) belonging to \(\mathfrak{hol}(\omega_{\text{nor}})\).

Usually, we do all our calculations with respect to the bi-invariant metric \(g_n\). According to this, we want to present the above formula for the conformal holonomy algebra in a more 'suggestive' form. Let us denote

\[ \mathfrak{L} := \text{span}\{ \gamma_0(a) | a \in m_{-1} \} \subset \mathfrak{p}_0. \]

This space is the span of the values in \(\text{so}(n)\) generated by the Levi-Civita connection of \(g_n\) and is isomorphic as Lie algebra to the derivations \(\text{Der}(n)\). Then it is

\[ \Lambda(m_{-1}) = \text{span}\{ \gamma^{-1}_0(l) + l + \gamma_1 \circ \gamma^{-1}_0(l) | l \in \mathfrak{L} \}. \]
In short, we use the notation $\Lambda(m_{-1}) = \gamma_{nor}^{-1}(\mathfrak{L}\mathfrak{C})$. This space is isomorphic to $\mathfrak{L}\mathfrak{C}$ as vector space, but it is not a subalgebra in $\mathfrak{g}$. Moreover, we set $\mathfrak{W} := \mathfrak{q}$, which just shall remember to the fact that $\mathfrak{q}$ is generated from the values of the Weyl tensor $W$ of $g_n$. Then our formula for the holonomy algebra takes the form

$$\mathfrak{hol}(\omega_{nor}) = \mathfrak{W} + [\gamma_{nor}^{-1}(\mathfrak{L}\mathfrak{C}), \mathfrak{W}] + [\gamma_{nor}^{-1}(\mathfrak{L}\mathfrak{C}), [\gamma_{nor}^{-1}(\mathfrak{L}\mathfrak{C}), \mathfrak{W}]] + \cdots .$$

To compare, the holonomy algebra of the Levi-Civita connection of the bi-invariant metric $g_n$ is given by

$$\mathfrak{hol}(g_n) = \mathfrak{R} + [\mathfrak{L}\mathfrak{C}, \mathfrak{R}] + [\mathfrak{L}\mathfrak{C}, [\mathfrak{L}\mathfrak{C}, \mathfrak{R}]] + \cdots ,$$

where $\mathfrak{R}$ denotes the space of images of the Riemannian curvature tensor to $g_n$.

6. Examples

We want to make some explicit use of the developed calculus for conformal geometry on bi-invariant metrics.

Example 1. Let $N = \text{SO}(3)$ be the special orthogonal group in dimension 3, which is a 3-dimensional compact and semisimple Lie group. Let $\mathfrak{so}(3)$ denote its Lie algebra. We use for $\mathfrak{so}(3)$ the standard basis $\{E_{ij} | 1 \leq i < j \leq 3\}$, were the $E_{ij}$’s are defined by matrix operations as

$$E_{ij} := e_i \cdot t e_j - e_j \cdot t e_i$$

with respect to the standard basis $(e_1, e_2, e_3)$ of $\mathbb{R}^3$.

The Lie algebra $\mathfrak{so}(3)$ is isomorphic to $\mathfrak{su}(2)$ and the universal covering of the group $\text{SO}(3)$ is

$$S^3 = \text{Spin}(3) \cong \text{SU}(2).$$

The bi-invariant metric on $\text{SO}(3)$ is conformally flat, since the Weyl tensor $W$ vanishes in dimension 3 in general, and $C$ vanishes for any bi-invariant metric. Of course, this is also clear from the fact that the bi-invariant metric on the universal covering group $\text{SU}(2)$ is the standard metric on $S^3$. For that reason, the calculations of conformal curvature and holonomy should produce trivial results here. The connection form $\gamma_{nor} = \gamma_0 + \gamma_1$ can be presented in the following form.

The chosen basis $\{E_{ij}\}$ in $\mathfrak{so}(3)$ is orthogonal and $-B(E_{ij}, E_{ij}) = 2$ for all its elements. We set the frame

$$\theta(\frac{1}{\sqrt{2}} E_{12}) = e_1, \quad \theta(\frac{1}{\sqrt{2}} E_{13}) = e_2, \quad \theta(\frac{1}{\sqrt{2}} E_{23}) = e_3 .$$

Then we find

$$\gamma_0(e_1) = -\frac{1}{\sqrt{2}} \nabla E_{12} = \frac{1}{2\sqrt{2}} [E_{12},.] = \frac{1}{2\sqrt{2}} E_{23} ,$$

$$\gamma_0(e_2) = -\frac{1}{\sqrt{2}} \nabla E_{13} = \frac{1}{2\sqrt{2}} [E_{13},.] = -\frac{1}{2\sqrt{2}} E_{13} ,$$

$$\gamma_0(e_3) = -\frac{1}{\sqrt{2}} \nabla E_{23} = \frac{1}{2\sqrt{2}} [E_{23},.] = \frac{1}{2\sqrt{2}} E_{12} .$$

For $\gamma_1$ we have

$$\gamma_1(e_i) = -\frac{1}{16} e_i^* \quad i = 1, 2, 3 .$$

These identities express the normal Cartan connection on $\text{SO}(3)$ in the trivialisation of the bi-invariant metric. In fact, one can see from this $\gamma_{nor}$ that the curvature $\kappa_0$ vanishes identically. In particular, the conformal holonomy group is trivial, which results from the formula in Theorem II with $q = 0$.

To complete the discussion, we state that the conformal automorphism group of the covering space $\text{SU}(2)$ is the Möbius group $\text{SO}(1, 4)$. However, the conformal automorphism group of $\text{SO}(3)$ consists only of the isometry group

$$\text{SO}(4)/\mathbb{Z}_2 = \text{SO}(3) \times \text{SO}(3) .$$
of the bi-invariant metric.

**Example 2.** We apply the conformal Cartan calculus now to the 6-dimensional compact and semisimple Lie group \( SO(4) \) with bi-invariant metric induced by the Killing form \( B \). The conformal automorphism group of \( SO(4) \) consists entirely of the isometries, which are the left and right translations, i.e. \( SO(4) \times SO(4) \). The Lie algebra \( \mathfrak{so}(4) \) is isomorphic to

\[
\mathfrak{so}(3) \oplus \mathfrak{so}(3)
\]

and as its basis we use two copies of the basis \( \{E_{ij}\} \) of \( \mathfrak{so}(3) \), namely

\[
\{E_{ij}, E_{kl} \mid 1 \leq i < j \leq 3 \text{ and } 4 \leq k < l \leq 6 \}.
\]

This basis is orthogonal with \(-B(E_{ij}, E_{ij}) = 2\) and it provides an embedding of \( \mathfrak{so}(4) \) into \( \mathfrak{so}(6) \).

The bi-invariant metric \( g_{\mathfrak{so}(4)} \) induced by the Killing form on \( SO(4) \) is Einstein with positive scalar curvature. Obviously, it has non-constant sectional curvature \( S \) (cf. paragraph [3]). Hence, it is not conformally flat. For that reason, we expect in our calculation non-trivial curvature and holonomy for the conformal structure \( e_{\mathfrak{so}(4)} \) on \( SO(4) \).

First, we calculate the normal connection form \( \gamma_{nor} = \gamma_0 + \gamma_1 \). We use the frame

\[
\theta\left(\frac{1}{\sqrt{2}}E_{12}\right) = e_1, \quad \theta\left(\frac{1}{\sqrt{2}}E_{13}\right) = e_2, \quad \theta\left(\frac{1}{\sqrt{2}}E_{23}\right) = e_3,
\]

\[
\theta\left(\frac{1}{\sqrt{2}}E_{45}\right) = e_4, \quad \theta\left(\frac{1}{\sqrt{2}}E_{46}\right) = e_5, \quad \theta\left(\frac{1}{\sqrt{2}}E_{56}\right) = e_6.
\]

From the calculations for the case of \( \mathfrak{so}(3) \) we get

\[
\gamma_0(e_1) = \frac{1}{2\sqrt{2}}E_{23}, \quad \gamma_0(e_2) = -\frac{1}{2\sqrt{2}}E_{13}, \quad \gamma_0(e_3) = \frac{1}{2\sqrt{2}}E_{12},
\]

\[
\gamma_0(e_4) = -\frac{1}{2\sqrt{2}}E_{56}, \quad \gamma_0(e_5) = -\frac{1}{2\sqrt{2}}E_{46}, \quad \gamma_0(e_6) = \frac{1}{2\sqrt{2}}E_{45}.
\]

The 1-part \( \gamma_1 \) is given by

\[
\gamma_1(e_i) = -\frac{1}{40}e_i^* \quad i = 1, \ldots, 6.
\]

The \((-1)\)-part \( \kappa_{-1} \) of the curvature vanishes, since \( \gamma_{nor} \) is torsion-free. The 1-part \( \kappa_1 \) also vanishes, since the Cotton-York tensor \( C \) of \( g_{\mathfrak{so}(4)} \) is zero. The 0-part \( \kappa_0 \) consists of the Weyl tensor \( W \). As next we have to calculate the images of \( \kappa_0 \), which will give us the space \( q \). It is

\[
W = R + \frac{1}{8(n-1)}g_n * g_n.
\]

For the Kulkarni-Nomizu product in this sum it is easy to see that

\[
\theta^*(B * B)(\theta^{-1}(e_i), \theta^{-1}(e_j)) \equiv \frac{1}{20}E_{ij} \quad \text{for all } i, j = 1, \ldots, 6.
\]

For the Riemannian curvature tensor we find

\[
\theta^* R_n(\theta^{-1}(e_i), \theta^{-1}(e_j)) = -\frac{1}{8}E_{ij}
\]

for all \( i, j \in \{1, \ldots, 3\} \) and \( i, j \in \{4, \ldots, 6\} \). The remaining curvature expressions for \( R_n \) are zero. This shows that the span of the 0-part \( \kappa_0 \) of the Cartan curvature is equal to \( \mathfrak{so}(6) \), which is the semisimple part of \( p_0 \) in the Möbius algebra \( \mathfrak{so}(1,7) \). Hence, we get for the span of the curvature values

\[
q = \mathfrak{so}(6) \subset p_0.
\]

Obviously, the span of the normal connection \( id + \gamma_{nor} \) is given by

\[
\Lambda(m_{-1}) = \{e_i + \gamma_0(e_i) - \frac{1}{40}e_i^* \mid i = 1, \ldots, 6\}.
\]
Then it is a straightforward calculation to see that the space $[\Lambda(m-1), q]$ of commutators is equal to
\[
\text{span}\{e_i - \frac{1}{40} e_i^* | i = 1, \ldots, 6\} \oplus \mathfrak{so}(6).
\]
We denote
\[
\mathfrak{l} := \text{span}\{x + \gamma_1(x) | x \in m_{-1}\}.
\]
The space $\mathfrak{l}$ is stable under the action of $\mathfrak{so}(6)$ sitting in $p_0$. This shows that all the spaces
\[
[\Lambda(m_{-1}), \cdots, [\Lambda(m_{-1}), q] \cdots]
\]
of commutators are equal to $\mathfrak{l} \oplus q$, which is seen to be isomorphic to the Lie algebra $\mathfrak{so}(7)$ embedded into $\mathfrak{so}(1, 7)$. We conclude for the holonomy algebra that
\[
\text{hol}(\omega_{\text{nor}}) = \mathfrak{l} \oplus q \cong \mathfrak{so}(7).
\]
The holonomy group of $\omega_{\text{nor}}$ on $\text{SO}(4)$ is then given by
\[
\text{Hol}(\omega_{\text{nor}}) = \text{SO}(7).
\]
This result has the following interpretation. The bi-invariant metric $g_n$ in the conformal class $c_n$ on $N = \text{SO}(4)$ is Einstein. It is well known in general that the conformal Einstein condition implies that the holonomy group $\text{Hol}(\omega_{\text{nor}})$ of the normal Cartan connection stabilizes a standard ‘tractor’, that is a vector in the standard representation $\mathbb{R}^{1,7}$ of the Möbius group $\text{SO}(1, 7)$ (cf. e.g. [Lei04a]).

In case that the scalar curvature of the Einstein metric is positive, this vector is timelike, which explains that for our case the holonomy group $\text{Hol}(\omega_{\text{nor}})$ of $\text{SO}(4)$ is automatically reduced to $\text{SO}(7)$. Our calculation then shows that the holonomy is not further reduced and we can say that $\text{SO}(4)$ has generic conformal holonomy up to the fact that it is (conformally) Einstein. In particular, we can read off from the holonomy result that $\text{SO}(4)$ does not admit any conformal Killing spinors nor normal conformal Killing forms. Also, there is no further Einstein metric in the conformal class $c_n$ beside the bi-invariant metric $g_n$ (cf. [Lei04a]).
