Abstract

Supersymmetric extensions of the Standard Model open up the possibility for new types of CP-violation. We consider the case of the Next-to-Minimal Supersymmetric Standard Model where, beyond the phases from the soft lagrangian, CP-violation could enter the Higgs sector directly at tree-level through complex parameters in the superpotential. We develop a series of Fortran subroutines, cast within the public tool NMSSMTools and allowing for a phenomenological analysis of the CP-violating NMSSM. This new tool performs the computation of the masses and couplings of the various new physics states in this model: leading corrections to the sparticle masses are included; the precision for the Higgs masses and couplings reaches the full one-loop and leading two-loop order. The two-body Higgs and top decays are also attended. We use the public tools HiggsBounds and HiggsSignals to test the Higgs sector. Additional subroutines check the viability of the sparticle spectrum in view of LEP-limits and constrain the phases of the model via a confrontation to the experimentally measured Electric Dipole Moments. These tools will be made publicly available in the near future. In this paper, we detail the workings of our code and illustrate its use via a comparison with existing results. We also consider some consequences of CP-violation for the NMSSM Higgs sector.

1 Introduction

After the discovery of a signal at a mass of about 125 GeV in the LHC Higgs searches [1,2], the question of the identification of the associated state(s) and the underlying physics remains open. While the general properties are consistent so far with those expected for the Higgs boson of the Standard Model (SM), a wide range of alternatives could equally well fit the experimental data. In particular, softly-broken supersymmetric (SUSY) extensions of the SM [3] count among the appealing options to solve the Hierarchy Problem [4] and allow for a smooth transition to higher energy physics (e.g. Grand Unification, neutrino physics or weakly-coupled dark matter). The scarceness of evidence for new physics effects in precision physics or direct searches should also be weighed by the considerations that SUSY-inspired models offer a SM-like decoupling regime, but also that complex mechanisms in the Higgs or SUSY sectors – see e.g. [5] – may account for this relative invisibility thus far.

The Next-to-Minimal Supersymmetric Standard Model (NMSSM), a singlet-extension of the simplest viable SUSY-inspired extension of the SM [6], has raised renewed interest ever since the Higgs discovery, notably due to its properties in the Higgs sector, e.g. allowing for an uplift of the mass of the SM-like Higgs related to F-terms or to the mixing of this state with a lighter singlet [7]. The original motivation for this singlet extension rests with the ‘μ-problem’ of the MSSM [8], which can be solved elegantly if this μ-term is generated dynamically, via a singlet vacuum expectation value (v.e.v.) [9]. Correspondingly, the $Z_3$-conserving version of the NMSSM – allowing only cubic terms in the superpotential – is the most studied form of this model, while more general singlet couplings can be justified by higher-energy considerations – see e.g. [10,11]. Another usual feature in SUSY extensions of the SM is R-parity, which both constrains the possibility of baryon-number violation and provides a stable SUSY particle, hence a dark-matter candidate.

A troubling fact rests with the observation that several NMSSM parameters – especially in the Higgs sector – can take complex values, hence lead to CP-violation beyond that in the quark sector. On the one hand, CP-violation is known as a cosmological necessity for baryogenesis. On the other, it receives severe limits at the phenomenological level, from the non-observation of Electric Dipole Moments (EDM’s; see e.g. [12]). In this paper, we aim at presenting a tool which allows to study the NMSSM with complex parameters within the framework of the public code NMSSMTools [13]. In a first step, we will focus on the $Z_3$-conserving version although we plan on a generalization to tadpole and quadratic couplings of the singlet in the future.
The current version of NMSSMTools allows to perform several operations in connection with the spectrum of the CP-conserving NMSSM: in particular, it computes radiative corrections to the Higgs and SUSY spectrum, calculates the widths of Higgs decays or confronts the NMSSM parameter space to theoretical – e.g. vacuum stability – or phenomenological – e.g. Higgs searches, B-physics – limits. Several other tools aiming at the calculation of rational corrections to the NMSSM spectrum have been developed in the past few years, e.g. NMSSMCALC [14] or SoftSUSY [15]. The latter focuses on the CP-conserving NMSSM, while NMSSMCALC allows for CP-violation but specializes in corrections to the Higgs spectrum. Other tools, less specialized in a given model, allow for similar manipulations, provided the implementation of a model-file as input: this applies to SPHENO [16] or FlexibleSUSY [17].

Our goal consists in generalizing NMSSMTools to the CP-violating case. While this task remains far from complete, the tools which we present here already allow for numerous operations: radiative corrections to the SUSY and the Higgs masses are implemented – so far, only the leading double-log corrections (beyond the full one-loop) are taken into account at two-loop order in the Higgs spectrum –; Higgs and top two-body decays are computed; phenomenological limits from LEP SUSY searches or Higgs physics are tested – the latter via an interface with the public tools HiggsBounds [18] and HiggsSignals [19] –; finally we designed a subroutine to estimate the EDM’s. All these routines should become available on the NMSSMTools website [13] in the near future.

This paper is intended to serve as a presentation of the calculations implemented in our tool, as well as a short illustration of its uses. In the following section, we will detail the characteristics of the model under study, the underlying assumptions and the tree-level spectrum. The third section will present the chain of subroutines that we designed and the operations which they carry out. Finally, we will consider phenomenological consequences and compare some of our predictions to the results of existing tools, before we conclude.

2 Model, Phase-counting and Tree-level

In this section, we present the details of the model under consideration, our notations as well as the spectrum at tree-level.

2.1 The CP-violating NMSSM

The NMSSM is a supersymmetry-inspired extension of the SM with soft SUSY-breaking terms. It differs from the minimal supersymmetric extension of the SM, the MSSM, in that it includes, in addition to the two Higgs $SU(2)_L$-doublet superfields $H_u$ and $H_d$ with opposite hypercharge $\pm 1$, a supplemental gauge-singlet chiral superfield $S$. While the couplings of this singlet may take a more complex form in the general case, we will be considering only the R-parity and $Z_3$-conserving NMSSM here, which is characterized by the following superpotential

\[ W = \lambda e^{i\phi} \bar{S}H_u \cdot \bar{H}_d + \frac{\kappa}{3} e^{i\phi_s} S^3 - H_u \cdot \bar{Q}_L[Y_u]U_R^c + \bar{H}_d \cdot \bar{Q}_L[Y_d]D_R^c + \bar{H}_d \cdot \bar{L}_L[Y_e]E_R^c \]

\[ - L_{\text{int}} = -M_1 e^{i\phi_3} \bar{b}\bar{b} - M_2 e^{i\phi_2} \bar{u}\bar{u}_a - M_1 e^{i\phi_3} \bar{u}\bar{u}_a + \text{h.c.} \]

\[ + m_H^2 |H_u|^2 + m_D^2 |H_d|^2 + m_S^2 |S|^2 + Q_L[m_Q^2]Q_L^c + U_R[m_U^2]U_R^c + D_R[m_D^2]D_R^c + L_L[m_L^2]L_L^c + E_R^c[m_E^2]E_R^c \]

\[ + \lambda A_i e^{i\phi_A} S \bar{H}_u \cdot H_d + \kappa A_r e^{i\phi_r} S^3 - H_u \cdot Q_L[Y_u A_u]U_R^c + H_d \cdot Q_L[Y_d A_d]D_R^c + H_d \cdot L_L[Y_e A_e]E_R^c + \text{h.c.} \]

\[ = \lambda e^{i\phi} \left( s + \frac{h_3^0 + a_0^0}{\sqrt{2}} \right) \]

\[ H_u = e^{i\phi_u} \left( v_u + \frac{h_u^0 + a_u^0}{\sqrt{2}} \right) \]

\[ H_d = e^{i\phi_d} \left( v_d + \frac{h_d^0 + a_d^0}{\sqrt{2}} \right) \]
The three ‘dynamical’ phases $\phi_s$, $\phi_u$ and $\phi_d$ add to the ‘static’ phases appearing in the lagrangian density (Eqs.12). From now on, we will make the following replacements in our notations:

\[
S \leftarrow \left( s + \frac{h_0^0 + m_s^0}{\sqrt{2}} \right) \\
H_u \leftarrow \left( \frac{H_u^+}{\sqrt{2}} + \frac{h_0^u + m_u^0}{\sqrt{2}} \right) \\
H_d \leftarrow \left( \frac{H_d^+}{\sqrt{2}} + \frac{h_0^d + m_d^0}{\sqrt{2}} \right)
\]

\[
\phi_s \leftarrow \phi_s + \phi_u + \phi_d \\
\phi_u \leftarrow \phi_u + 3\phi_s \\
\phi_A \leftarrow \phi_A + \phi_s + \phi_u + \phi_d \\
\phi_A \leftarrow \phi_A + 3\phi_s
\]

The three ‘dynamical’ phases $\phi_s$, $\phi_u$ and $\phi_d$ add to the ‘static’ phases appearing in the lagrangian density (Eqs.12). From now on, we will make the following replacements in our notations:

\[
H \leftarrow \left( \frac{H_u^+ + \phi_s}{\sqrt{2}} + \frac{h_0^u + m_u^0}{\sqrt{2}} \right) \\
H_d \leftarrow \left( \frac{H_d^+ + \phi_s}{\sqrt{2}} + \frac{h_0^d + m_d^0}{\sqrt{2}} \right)
\]

\[
\phi_s \leftarrow \phi_s + \phi_u + \phi_d \\
\phi_u \leftarrow \phi_u + 3\phi_s \\
\phi_A \leftarrow \phi_A + \phi_s + \phi_u + \phi_d \\
\phi_A \leftarrow \phi_A + 3\phi_s
\]

The Yukawa matrices may be written in terms of (real and positive) matrices $Y_u$, $Y_d$, $Y_e$, diagonal in flavour space, using unitary transformations:

\[
Y_u \leftarrow Y_u e^{i\phi_u} \\
Y_d \leftarrow Y_d e^{i\phi_d} \\
Y_e \leftarrow Y_e e^{i\phi_e}
\]

Finally, we make the following assumptions to ensure minimal flavour violation in the sfermion sector:

- $X_{L,R}^{u,u}$ and $X_{L,R}^{d,d}$ are assumed diagonal. 
- $X_{L,R}^{u,d}$ and $X_{L,R}^{d,u}$ are assumed proportional to the identity, in the strict sense, but is viable, considering that the CKM matrix is hierarchical. Note that we will assume degeneracy in flavour space. The approximation ‘$\equiv$’ only holds for a matrix proportional to the identity, in the strict sense, but is viable, considering that the CKM matrix is hierarchical. Note that we will assume degeneracy for the first two generations of sfermions.

Consequently, the soft SUSY-breaking lagrangian of Eq.1 reduces to:

\[
- \mathcal{L}_{soft} = -M_1 e^{i\phi_1} \bar{H}_u H_d + M_2 e^{i\phi_2} \bar{H}_d H_u + M_3 e^{i\phi_3} \bar{\tilde{g}}_a \tilde{g}_a + h.c.
\]

\[
+ \left( m_{\tilde{u}}^2 \left( D_2 L + D_2 U \right) + m_{\tilde{d}}^2 \left( D_1 U + D_1 L \right) + m_{\tilde{d}}^2 \left( D_2 L + D_2 U \right) + m_{\tilde{d}}^2 \left( D_1 U + D_1 L \right) \right) + m_{\tilde{S}}^2 \left( N_L N_L + E_L^+ E_L \right)
\]

\[
+ m_{\tilde{H}_d}^2 |H_d|^2 + m_{\tilde{H}_u}^2 |H_u|^2 + m_{\tilde{S}}^2 |S|^2 + \left[ \lambda A_{\tilde{u}} e^{i\phi_1} S H_d \cdot H_u + \frac{\lambda}{3} A_{\tilde{d}} e^{i\phi_2} S H_u \cdot H_u + \frac{\lambda}{3} A_{\tilde{d}} e^{i\phi_2} S H_d \cdot H_d + L \tilde{L} \tilde{E}_R^+ \tilde{E}_R^+ \right]
\]

Eqs.1 and 12 fully characterize the model that we will be considering from now on – note that the three latter terms of Eq.1 as well as the second and fourth lines of Eq.12 are still implicitly summed over fermion generations. All the phases have been explicidtly and reduce, at this level, to four phases in the Higgs sector – $\phi_s$, $\phi_u$, $\phi_d$, $\phi_e$ – and the CKM phase finally. Given that we will neglect the Yukawa couplings of the first two generations, only the sfermion phases of the third generation will intervene in practice.
2.2 The tree-level Higgs sector

The Higgs potential collects terms from the soft lagrangian (Eq[8]), F-terms from the superpotential (Eq[7] and D-terms from the gauge interactions. We obtain:

\[
\mathcal{V}_H = m_{H_u}^2 |H_u|^2 + m_{H_d}^2 |H_d|^2 + m_S^2 |S|^2 + \lambda \Lambda [e^{i\phi_1}SH_u \cdot H_d + h.c.] + \frac{\kappa}{3} \Lambda [e^{i\phi_2}S^3 + h.c.]
\]

\[
+ \lambda^2 \left[ |S|^2 (|H_u|^2 + |H_d|^2) + |H_u \cdot H_d|^2 \right] + \kappa \lambda \left[ e^{i(\phi_1 - \phi_2)} S^2 H_u \cdot H_d + h.c. \right] + \kappa^2 |S|^4
\]

\[
+ \frac{g^2 + g'^2}{8} \left[ |H_u|^2 - |H_d|^2 \right]^2 + \frac{g^2}{2} |H_dH_u|^2
\] (9)

The neutral part reduces to:

\[
\mathcal{V}_{H^0} = m_{H_u}^2 |H_u^0|^2 + m_{H_d}^2 |H_d^0|^2 + m_S^2 |S|^2 - \lambda \Lambda [e^{i\phi_1}SH_u H_d^0 + h.c.] + \frac{\kappa}{3} \Lambda [e^{i\phi_2}S^3 + h.c.]
\]

\[
+ \lambda^2 \left[ |S|^2 (|H_u^0|^2 + |H_d^0|^2) + |H_u^0|H_d^0|^2 \right] - \kappa \lambda \left[ e^{i(\phi_1 - \phi_2)} S^2 H_u^0 H_d^0 + h.c. \right] + \frac{g^2 + g'^2}{8} \left[ |H_u^0|^2 - |H_d^0|^2 \right]^2
\] (10)

At tree level, the Higgs v.e.v.'s are assumed to minimize this potential. A consequence is the cancellation of first derivatives with respect to the neutral Higgs fields at the minimum, which provides us with the minimization conditions:

\[
m_{H_u}^2 = \lambda s [\Lambda \cos \phi_1 + \kappa s \cos(\phi_1 - \phi_2)] \frac{v_u}{v_d} - \lambda^2 (s^2 + v_d^2) - \frac{g^2 + g'^2}{4} (v_u^2 - v_d^2)
\]

\[
m_{H_d}^2 = \lambda s [\Lambda \cos \phi_1 + \kappa s \cos(\phi_1 - \phi_2)] \frac{v_u}{v_d} - \lambda^2 (s^2 + v_d^2) - \frac{g^2 + g'^2}{4} (v_u^2 - v_d^2)
\]

\[
m_S^2 = \lambda \Lambda \cos \phi_1 + 2\kappa s \cos(\phi_1 - \phi_2) \frac{v_u v_d}{s} - \kappa s [\Lambda \sin \phi_1 + 2\kappa s] - \lambda^2 (v_u^2 + v_d^2)
\]

(11)

\[A_s \sin \phi_1 = -\kappa s \sin(\phi_1 - \phi_2)\]

\[A_s \sin \phi_2 = \frac{\lambda}{s} [A_s \sin \phi_1 - 2\kappa s \sin(\phi_1 - \phi_2)] \frac{v_u v_d}{s} = -3\lambda v_u v_d s \sin(\phi_1 - \phi_2)
\]

Here we see that the four phases of the Higgs sector are not independent but that, on the contrary, the minimization conditions relate \(\phi_1\) and \(\phi_2\) to \(\phi_1 - \phi_2\), the latter being the one and only ‘observable’ phase in the Higgs sector. Note that \(\phi_1\) and \(\phi_2\) intervene independently in other parts of the spectrum however. We will make an explicit use of the minimization conditions of Eq[11] in the following lines, replacing \(m_{H_u}^2, m_{H_d}^2, m_S^2, A_s \sin \phi_1\) and \(A_s \sin \phi_2\) by their expressions in terms of the v.e.v.’s.

The terms of Eq[9] bilinear in the charged Higgs fields, define the \(2 \times 2\) (hermitian) mass-matrix of the charged-Higgs states:

\[
\mathcal{V}_H \ni (H_u^-, H_d^-) \langle M_{H^\pm}^2 \rangle \left( \begin{array}{c} H_u^- \\ H_d^- \end{array} \right) \rightarrow
\]

\[
\langle M_{H^\pm}^2 \rangle = \left( \begin{array}{cc} \lambda s [\Lambda \cos \phi_1 + \kappa s \cos(\phi_1 - \phi_2)] - \left( \lambda^2 - \frac{g^2}{2} \right) v_u v_d & \frac{v_u}{v_d} \\ -\sin \beta & \cos \beta \end{array} \right) \left( \begin{array}{cc} 0 & 1 \\ 0 & \frac{1}{v_d} \end{array} \right)
\] (12)

\[m_{H^\pm}^2 = \left( \begin{array}{c} \lambda s [\Lambda \cos \phi_1 + \kappa s \cos(\phi_1 - \phi_2)] - \left( \lambda^2 - \frac{g^2}{2} \right) (v_u^2 + v_d^2) \end{array} \right) ; \quad \tan \beta = \frac{v_u}{v_d}
\]

which determines the charged Goldstone boson \(G^\pm = -\sin \beta H_u^\pm + \cos \beta H_d^\pm\) and the physical charged Higgs state \(H^\pm = \cos \beta H_u^\pm + \sin \beta H_d^\pm\).

Similarly, the terms bilinear in the neutral Higgs fields provide the \(6 \times 6\) (symmetric) mass-matrix of the neutral Higgs: \(\langle M_{H^0}^2 \rangle_{ij} = \frac{1}{2} \left( \begin{array}{cc} \frac{\sigma^2 v_u}{\sqrt{2} v_d^2 s} & \frac{\sigma^2 v_u}{\sqrt{2} v_d^2 s} \end{array} \right)\), with the notation \(\langle \cdots \rangle\) meaning that fields are frozen to their v.e.v.’s. In
As in the charged case, the neutral Goldstone boson can be singled out via a doublet subspace via rotations of angle $\beta$. The vacuum. Remember also that the positivity of the squared Higgs-masses is a stability condition of the vacuum. Additionally, we define $X^{R}_{i} \equiv \cos \beta X_{i}^{L}$. Note that the positivity of the squared Higgs-masses is a stability condition of the vacuum. Remember also that the positivity of the squared Higgs-masses is a stability condition of the vacuum. Additionally, we define $X^{R}_{i} \equiv \cos \beta X_{i}^{L}$.

As in the charged case, the neutral Goldstone boson can be singled out via a $\beta$-angle rotation $G^{0} \equiv -\sin \beta a^{0} + \cos \beta a^{0}$. The remaining $5 \times 5$ symmetric block spanning the space $(h_{u}^{0}, h_{d}^{0}, h_{s}^{0}, a^{0}, a_{s}^{0})$ may be diagonalized via an orthogonal matrix $X^{H}$:

$$\langle M_{3}^{2} \rangle = X^{H \top} \text{diag}(m_{S_{i}^{0}}^{2}, i = 1, \ldots, 5) X^{H}$$

which defines the mass eigenstates:

$$S_{i}^{0} = X_{i1}^{H} h_{u}^{0} + X_{i2}^{H} h_{d}^{0} + X_{i3}^{H} h_{s}^{0} + X_{i4}^{H} a^{0} + X_{i5}^{H} a_{s}^{0} \equiv X_{i1}^{R} h_{u}^{0} + X_{i2}^{R} h_{d}^{0} + X_{i3}^{R} h_{s}^{0} + X_{i4}^{R} a^{0} + X_{i5}^{R} a_{s}^{0}$$

We will use the second notation which allows more clarity in the identification of the components. Additionally, we define $X_{i}^{L} \equiv \cos \beta X_{i}^{R}$ and $X_{id}^{L} \equiv \sin \beta X_{id}^{R}$.

2.3 The supersymmetric spectrum at tree-level

The whole tree-level spectrum will be treated with further details in appendix. Here we simply summarize, for the sake of notations, the basic ingredients concerning the treatment of masses and mixings of SUSY particles.

i) Gluinos

The gluinos are the fermionic partners of the gluons and, as such, form a color octet. Their bilinear terms originate in the soft lagrangian: $-\mathcal{L}_{soft} \supset -M_{3}^{2} \tilde{g}_{a} \tilde{b}_{a}$. The mass states $\tilde{g}_{a}$, with mass $M_{3}$ (which we assume positive), then relate to the eigenstates of the SUSY vector superfield $\tilde{g}_{a}$ as $\tilde{g}_{a} \equiv -\epsilon \tilde{G}_{a}$. The phase shift then affects the couplings of the gluinos to coloured matter.
\[ \mathcal{V}_{\chi^\pm} \supset \frac{1}{2} \chi^{\dagger} \left( \begin{array}{c} 0 \\ \langle \mathcal{M}_{\chi^{\pm}} \rangle \end{array} \right) \chi^{\pm} + \text{h.c.} \ ; \ \langle \mathcal{M}_{\chi^{\pm}} \rangle \equiv (-i\tilde{u}^-, \tilde{h}_d^-, -i\tilde{u}^+, \tilde{h}_d^+) \]

\[ \langle \mathcal{M}_{\chi^{0}} \rangle = \left( \begin{array}{cccc} M_{1e^{i\phi_{11}}} & \bar{v} & -\frac{g'}{2} v_u & 0 \\ 0 & M_{2e^{i\phi_{22}}} & -\frac{\sqrt{2}}{2} v_d & 0 \\ \frac{g'}{2} v_u & \frac{g'}{2} v_d & -\lambda e^{i\varphi_{33}} s & \frac{\lambda e^{i\varphi_{33}} s}{2}\tilde{g}^0 \\ 0 & 0 & \frac{\lambda e^{i\varphi_{33}} s}{2}\tilde{g}^0 & -\lambda e^{i\varphi_{33}}\tilde{v}_d \end{array} \right) \]

We may diagonalize \( \langle \mathcal{M}_{\chi^{\pm}} \rangle \) with the help of two unitary matrices \( U \) and \( V \): \( \langle \mathcal{M}_{\chi^{\pm}} \rangle = U^T \text{diag}(m_{\chi^\pm}^0, m_{\chi^\pm}^0) V \). The mass eigenvalues may be assumed real and positive without any loss of generality and the mass eigenstates \((i = 1, 2)\) relate to the gauge ones as:

\[ \chi_i^+ = V_{11}(-i\tilde{u}^+) + V_{21}\tilde{h}_d^+ \equiv V_{uw}(-i\tilde{u}^+) + V_{ub}\tilde{h}_d^+ \ ; \ \chi_i^- = U_{11}(-i\tilde{u}^-) + U_{21}\tilde{h}_d^- \equiv U_{uw}(-i\tilde{u}^-) + U_{ub}\tilde{h}_d^- \]  

\[ \chi_i^0 = N_{i1}(-i\tilde{b}) + N_{i2}(-i\tilde{u}^3) + N_{i3}\tilde{h}_u^0 + N_{i4}\tilde{h}_d^0 + N_{i5}\tilde{h}_s^0 \equiv N_{i\tilde{b}}(-i\tilde{b}) + N_{i\tilde{u}^3}(-i\tilde{u}^3) + N_{i\tilde{u}}\tilde{h}_u^0 + N_{i\tilde{b}}\tilde{h}_d^0 + N_{i\tilde{u}}\tilde{h}_s^0 \]

\[ \chi_i^0 = N_{i1}(-i\tilde{b}) + N_{i2}(-i\tilde{u}^3) + N_{i3}\tilde{h}_u^0 + N_{i4}\tilde{h}_d^0 + N_{i5}\tilde{h}_s^0 \equiv N_{i\tilde{b}}(-i\tilde{b}) + N_{i\tilde{u}^3}(-i\tilde{u}^3) + N_{i\tilde{u}}\tilde{h}_u^0 + N_{i\tilde{b}}\tilde{h}_d^0 + N_{i\tilde{u}}\tilde{h}_s^0 \]

\[ \mathcal{M}_{\chi^{0}} \] being symmetric, it can be diagonalized by a single unitary matrix \( N \) according to:

\[ \mathcal{M}_{\chi^{0}} = N^T \text{diag}(m_{\chi^0}, i = 1, \ldots, 5)N \]. Without loss of generality the eigenvalues \( m_{\chi^0} \) can be chosen real and positive (remember that \( N \) is complex) and the mass eigenstates relate to the gauge ones in the following fashion:

\[ \chi_i^0 = N_{i1}(-i\tilde{b}) + N_{i2}(-i\tilde{u}^3) + N_{i3}\tilde{h}_u^0 + N_{i4}\tilde{h}_d^0 + N_{i5}\tilde{h}_s^0 \equiv N_{i\tilde{b}}(-i\tilde{b}) + N_{i\tilde{u}^3}(-i\tilde{u}^3) + N_{i\tilde{u}}\tilde{h}_u^0 + N_{i\tilde{b}}\tilde{h}_d^0 + N_{i\tilde{u}}\tilde{h}_s^0 \]

\[ \mathcal{M}_{\chi^{0}} \] being symmetric, it can be diagonalized by a single unitary matrix \( N \) according to:

\[ \mathcal{M}_{\chi^{0}} = N^T \text{diag}(m_{\chi^0}, i = 1, \ldots, 5)N \]. Without loss of generality the eigenvalues \( m_{\chi^0} \) can be chosen real and positive (remember that \( N \) is complex) and the mass eigenstates relate to the gauge ones in the following fashion:

\[ \chi_i^0 = N_{i1}(-i\tilde{b}) + N_{i2}(-i\tilde{u}^3) + N_{i3}\tilde{h}_u^0 + N_{i4}\tilde{h}_d^0 + N_{i5}\tilde{h}_s^0 \equiv N_{i\tilde{b}}(-i\tilde{b}) + N_{i\tilde{u}^3}(-i\tilde{u}^3) + N_{i\tilde{u}}\tilde{h}_u^0 + N_{i\tilde{b}}\tilde{h}_d^0 + N_{i\tilde{u}}\tilde{h}_s^0 \]

\[ \mathcal{M}_{\chi^{0}} \] being symmetric, it can be diagonalized by a single unitary matrix \( N \) according to:

\[ \mathcal{M}_{\chi^{0}} = N^T \text{diag}(m_{\chi^0}, i = 1, \ldots, 5)N \]. Without loss of generality the eigenvalues \( m_{\chi^0} \) can be chosen real and positive (remember that \( N \) is complex) and the mass eigenstates relate to the gauge ones in the following fashion:

\[ \chi_i^0 = N_{i1}(-i\tilde{b}) + N_{i2}(-i\tilde{u}^3) + N_{i3}\tilde{h}_u^0 + N_{i4}\tilde{h}_d^0 + N_{i5}\tilde{h}_s^0 \equiv N_{i\tilde{b}}(-i\tilde{b}) + N_{i\tilde{u}^3}(-i\tilde{u}^3) + N_{i\tilde{u}}\tilde{h}_u^0 + N_{i\tilde{b}}\tilde{h}_d^0 + N_{i\tilde{u}}\tilde{h}_s^0 \]
3 A short walk-through the code

In this section, we shall describe the operations which are conducted throughout our subroutines from the perspective of the phenomenology of the CP-violating NMSSM.

3.1 Interface with NMSSMTools

Before coming to the actual computations of our code, let us remind the reader that we embed it within the NMSSMTools package. We actually use the NMHDECAY routines to define its input. In particular, we do not alter the running of parameters – such as the Yukawa, gauge or soft couplings, e.g., to the average scale of the squarks of third generation. We simply use the corresponding quantities as calculated by NMHDECAY as our input and introduce the complex phases at this level. This is sufficient in consideration of the order of precision which we aim at in the radiative corrections. A short subroutine init_CPV.f defines this interface and stores all the relevant quantities within commons of the code. The case of the parameters $A_1$ and $A_h$ is somewhat more subtle: given that the phases $\varphi_1$ and $\varphi_2$ are not free but, in our approach, determined by the minimization conditions of the potential (see Eq[11]), we will only be using the quantities $A_1 \cos \varphi_1$ and $A_h \cos \varphi_2$ as degrees of freedom in practice. Therefore, we identify the NMHDECAY input for $A_1$ and $A_h$ as ours for $A_1 \cos \varphi_1$ and $A_h \cos \varphi_2$. The wave-function scaling factors for the Higgs fields are also defined slightly differently from the original implementation in NMSSMTools, as we shall describe in section 3.3.1.

Given our discussion in section 2 the following eight phases are added as new degrees of freedom: $\varphi_{\lambda}$, $\varphi_{\kappa}$, $\phi_{M_1}$, $\phi_{M_2}$, $\phi_{\mu}$, $\varphi_{A_0}$, $\varphi_{A_1}$, $\varphi_{A_2}$.

3.2 Supersymmetric spectrum

The first actual operations which are carried out in connection to the CP-violating NMSSM consist in the calculation of the masses of the supersymmetric matter content. Similarly to the evaluation by NMSSMTools in the CP-conserving case, we take into account the leading radiative corrections to the masses. In the following, we list the new subroutines and provide relevant information concerning the calculations which are performed.

i) mcha_CPV.f

The purpose of this subroutine rests in diagonalizing the chargino mass matrix (Eq[7]) according to $\langle M_{\chi^\pm} \rangle = U^T \text{diag}(m_{\chi^\pm}) V$. Similarly to the corresponding implementation within NMSSMTools for the CP-conserving case, the entries of the mass matrix receive one-loop radiative corrections which are calculated in the approximation where mass and gauge eigenstates coincide. The corresponding effects are presented in section 4.2 of [20] in the context the MSSM and still in the CP-conserving case. Small modifications appear in the CP-violating NMSSM, as gaugino and higgsino scalar couplings are rotated by phase factors of $e^{-i \phi_1 / 2}$ and $e^{-i \phi_2 / 2}$. Nevertheless, the factors of $B_1$ functions as well as the corrections involving gauge bosons are immune to this phase shift, so that only the scalar interactions resulting in a $B_0$ function – in the approximations of [20], this reduces to the Higgs / higgsino loops – are affected. Another difference with respect to ref. [20] originates from the presence of singlets and singlinos in the higgsino self-energies. A summary of these corrections is explicated in appendix B.1.4.

The following steps are essentially identical to their counterparts in the tree-level case, which is treated into details in appendix B.1.4 we define two special-unitary matrices $U_0$ and $V_0$ diagonalizing the hermitian matrices $\langle M_{\chi^\pm} \rangle \langle M_{\chi^\pm} \rangle^\dagger$ and $\langle M_{\chi^0} \rangle \langle M_{\chi^0} \rangle^\dagger$ respectively. $U_0^\dagger \langle M_{\chi^\pm} \rangle V_0^\dagger$ is then a diagonal matrix with, in general, non-real entries. We thus define the unitary matrices $U$ and $V$ via a phase-shift of $U_0$ and $V_0$, where the phase of the lightest state is absorbed in $U$ while that of the heavier one is absorbed in $V$: the resulting chargino masses are real and positive.

ii) mneu_CPV.f

The case of the neutralinos follows the same principles as that of the charginos. The tree-level gaugino and higgsino masses are corrected in accordance with the one-loop effects presented in appendix C.1. We then diagonalize the complex symmetric neutralino mass matrix according to $\langle M_{\chi^0} \rangle = N^T \text{diag}(m_{\chi^0}, i = 1, \ldots, 5) N$. For that purpose, we consider the $10 \times 10$ real symmetric matrix $\left( \begin{array}{cc} \text{Re} & \text{Im} \\ -\text{Im} & \text{Re} \end{array} \right) \left( \langle M_{\chi^0} \rangle ^\dagger \langle M_{\chi^0} \rangle \right)$, which can be diagonalized numerically by an orthogonal matrix $N_0$. We then extract a special unitary matrix $N_0$ so that $N_0^\dagger \langle M_{\chi^0} \rangle N_0^\dagger$ is diagonal. We finally absorb the remaining phases in a phase-shift of $N_0$, which defines the real and positive neutralino masses as well as the mixing matrix $N$. Details are provided in appendix B.1.4.

iii) msferm_CPV.f

We now turn to the sfermion masses. The hermitian tree-level mass matrices are diagonalized via special-unitary
matrices $X^F$, according to $\langle M_F^2 \rangle = X^F \text{diag}(m_{F_1}^2, m_{F_2}^2) X^F$. We remind the reader that the parameters entering the matrices, e.g. the top and bottom Yukawa couplings, have been run to the average squark scale. The Yukawa couplings of the first two generation are neglected, so that the corresponding diagonalizing matrices are trivial. Details can be found in appendix B.1.3.

We then apply $O(\alpha_S)$ corrections to the squark squared masses (consistently with what was implemented in the original CP-conserving treatment in NMSSMTools). Gluons, gluinos as well as the quartic sfermion D-term contribute to the sfermion self energy at this order. CP-phases – here, $\phi_{M_1^i}$ and $\phi_{A_1}$ – intervene in the gluino-sfermion couplings leading to a $B_0$ function. A summary is proposed in appendix C.2.

Finally, we check the positivity of the sfermion squared masses, a vacuum-stability requirement.

$iv)$ mgluino_CPV.f

mgluino_CPV.f computes the gluino mass, including the $O(\alpha_S)$ radiative corrections, which are obtained in a similar manner to the discussion in section 4.1 of [20]. Relevant corrections include the gluon / gluino and the quark / squark loops. Complex phases again enter the couplings of gluinos to squarks. Details are provided in appendix C.3.

3.3 Higgs masses and radiative corrections

The following series of subroutines aim at computing the Higgs masses and mixing, including full one-loop and leading two-loop corrections. Consistently with the original approach in NMHDECAY, we will consider the effective Higgs potential at the average scale of the squarks of the third generation – denoted as $Q$ –, where the running parameters are thus evaluated.

3.3.1 Wave-function renormalization

Momentum-dependent radiative corrections can be included in two fashions within the effective potential evaluation: one may reject them to the end of the calculation, as ‘pole-corrections’, or one may take them into account – at least partially – into the effective lagrangian as corrections to the kinetic terms. The latter choice leads to wave-function renormalization factors. While the two methods are formally equivalent, they lead to slightly divergent results at the numerical level, as we will discuss later. Following the original approach in NMHDECAY – presented e.g. in appendix C of [21] or appendix C of [6] –, we decide to include the leading $p^2$ terms – where $p$ stands for the external energy-momentum of the Higgs self-energies –, originating in fermion or gauge effects, into the kinetic term of the effective lagrangian. Nevertheless, since we aim at a full computation at one-loop, all the missing momentum-dependent parts will be added as pole-corrections (see below).

In the general case, the modified Higgs kinetic terms involve a hermitian (non-degenerate) matrix $Z_H(p^2)$ as follows (here and below $S_i$ denotes any Higgs field; we work in momentum space and omit the factor 1/2 which should appear if the considered field is real):

$$\hat{L}^\alpha_{\text{kin}} = \sum_{i,j} p^2 Z_H(p^2)_{ij} S^*_i S_j$$

The normal procedure then consists in rotating and scaling $Z_H$ via an invertible matrix $O_H$ in order to recover the identity – $Z_H(p^2) = O_H^\dagger O_H$ –, then considering the ‘new’ set of fields with standard kinetic term $\hat{S}_i \equiv O_H S_i$.

Yet, Eqs.(C.1) of [21] or (C.9-11) of [6] show that a clever choice of the corrections included into $Z_H$ can make this procedure particularly simple, as $Z_H$ would turn out to be diagonal in the base of gauge-eigenstates. Restricting to neutral Higgs fields, one has (with $\delta_{S_i,S_j}$ denoting the Kronecker symbol):

$$Z_H_{ij} \equiv Z_{H_u} \left[ \delta_{S_i,S_u} \delta_{S_j,S_u} + \delta_{S_i,S_d} \delta_{S_j,S_d} + \delta_{S_i,S_e} \delta_{S_j,S_e} \right] + Z_{H_d} \left[ \delta_{S_i,S_u} \delta_{S_j,S_d} + \delta_{S_i,S_d} \delta_{S_j,S_u} + \delta_{S_i,S_e} \delta_{S_j,S_e} \right] + Z_S \left[ \delta_{S_i,S_u} \delta_{S_j,S_u} + \delta_{S_i,S_d} \delta_{S_j,S_d} + \delta_{S_i,S_e} \delta_{S_j,S_e} \right]$$

Indeed, considering the contributions of SM-fermions to $Z_{H_u}$ ($N_u = 3$ is the colour factor; while using the generic notations $u, d, e$, we will be considering only the third generation fermions since we neglect the Yukawa couplings of the two first families), the deviations of the diagonal scaling factors from unity read

$$\delta_{\text{SM form}} Z_{H_u} = \frac{1}{16\pi^2} \left\{ N_u Y^2_u B_0(p, m_u, m_u) \right\}$$
$$\delta_{\text{SM form}} Z_{H_d} = \frac{1}{16\pi^2} \left\{ N_u Y^2_u B_0(p, m_d, m_d) + Y^2_e B_0(p, m_e, m_e) \right\}$$
$$\delta_{\text{SM form}} Z_S = 0$$

$^2$Loop functions are defined in appendix A.
Similarly, in the approximation where higgsinos and gauginos are simultaneously gauge and mass eigenstates ($\mu$ denotes the doublet higgsino mass; $m_i$, the singlino mass):
\[
\begin{align*}
\delta^h\delta Z_{H_u} &= \frac{1}{16\pi^2} \left\{ \frac{g^2}{2} B_0(p, M_1, \mu) + \frac{3g^2}{2} B_0(p, M_2, \mu) + \lambda^2 B_0(p, \mu, m_i) \right\} \\
\delta^h\delta Z_{H_d} &= \delta^h\delta Z_{H_u} \\
\delta^h\delta Z_S &= \frac{1}{8\pi^2} \left\{ \lambda^2 B_0(p, \mu, \mu) + \kappa^2 B_0(p, m_i, m_i) \right\}
\end{align*}
\]
(24)

The last source of corrections to $Z_H$ is the gauge sector – note that we will be working in the Feynmann gauge. Yet, the corresponding contributions are not diagonal in the gauge eigenbase, but rotated by an angle $\beta$ (or $-\beta$, depending on the CP-eigenvalue) in the doublet sector. Noticing however that $\tan \beta > 1$ in practice, we may keep the $\sin^2 \beta$ term in the wave-function scaling while rejecting the remaining $\sin \beta \cos \beta$ and $\cos^2 \beta$ terms for later treatment as pole-corrections. Then:
\[
\begin{align*}
\delta^{\text{gauge}} Z_{H_u} &= -\frac{\sin^2 \beta}{16\pi^2} \left\{ \frac{g^2}{2} B_0(p, M_W, M_W) + \frac{g^2 + g^2}{2} B_0(p, M_Z, M_Z) \right\} \\
\delta^{\text{gauge}} Z_{H_d} &= 0 \\
\delta^{\text{gauge}} Z_S &= 0
\end{align*}
\]
(25)

Note that this choice in the gauge sector differs from the default treatment by NMSSMTools in the CP-conserving case (see Eq.(C.9-10) of [6]), where, moreover, pole corrections from the gauge sector are ignored.

Before setting $Z_{H_u, H_d, S} = 1 + \left[ \delta^{\text{gauge}} \delta^{h\delta} + \delta^{\text{gauge}} \delta^{h\delta} \right] Z_{H_u, H_d, S}$, one is confronted to the remaining $p^2$-dependence of these coefficients (via the loop functions $B_0$). In the ideal case, $p^2$ would match the Higgs squared masses. This, however, is impractical since several mass eigenvalues are present: keeping this $p^2$ dependence, hence working with $p^2$-dependent fields and mass-matrices, and setting this implicit dependence separately to the corresponding Higgs squared mass after diagonalization of the mass matrix would be possible, yet problematic in a numerical evaluation of the mass matrices. The choice of [6] in the CP-conserving case rested in adding an artificial dependence of $Z_{H_u, H_d}$ on $\ln(M_A^2/m_1^2) - M_A$ standing for the mass of the heavy doublet, $m_t$ approximating the SM-like Higgs mass $\mu$, so as to mimic the correct logarithmic dependence after rotation by an angle $-\beta$ (approximating the tree-level diagonalizing rotation in the CP-even doublet sector): however an explicit rotation by the angle $-\beta$ shows that this purpose is missed as only the light state receives the proper logarithmic factor; in the case of the heavy doublet, the factor is wrong so that the result does not really improve on neglecting the logarithms $\ln(M_A^2/m_1^2)$ altogether. Therefore, we settle for the choice which consists in freezing the external momentum to a scale $\mu_H = 125$ GeV, allowing for a good precision in the characteristics of the SM-like Higgs state – the most sensitive to radiative corrections. Adequate corrections when the mass is far from this scale are rejected to the level of pole-corrections. A final difference with [6] comes from the implementation of the loop functions: we explicitly compute the full relevant $B_0$’s while [6] only included the leading logarithmic terms in case of large mass hierarchies.

A summary of the wave-function scaling factors is provided in appendix [12].

Consistently, the neutral higgs fields are rescaled as:
\[
\begin{align*}
h_u^0 &\leftarrow \frac{h_u^0}{\sqrt{Z_{H_u}}} ; & h_d^0 &\leftarrow \frac{h_d^0}{\sqrt{Z_{H_d}}} ; & b_u^0 &\leftarrow \frac{b_u^0}{\sqrt{Z_S}} ; & a_u^0 &\leftarrow \frac{a_u^0}{\sqrt{Z_{H_u}}} ; & a_d^0 &\leftarrow \frac{a_d^0}{\sqrt{Z_{H_d}}} ; & a_S^0 &\leftarrow \frac{a_S^0}{\sqrt{Z_S}}
\end{align*}
\]
(26)

so that all related quantities (e.g. the mass matrices) must be rescaled accordingly. In particular the Higgs v.e.v.’s:
\[
\begin{align*}
v_u(Q) &\equiv \frac{v_u}{\sqrt{Z_{H_u}}} ; & v_d(Q) &\equiv \frac{v_d}{\sqrt{Z_{H_d}}} ; & s(Q) &\equiv \frac{s}{\sqrt{Z_S}}
\end{align*}
\]
(27)

All these operations are carried out in the initialization subroutine init_CPV.f.

In the charged-sector, the $p^2$-dependent terms are typically different from those appearing in the neutral case. However, to keep $\beta$ as the relevant rotation angle in the charged sector together with the v.e.v. rescaling of Eq.\[(27)\] we will use the same wave-function scaling factors $Z_{H_u, H_d}$:
\[
\begin{align*}
H_u^0 &\leftarrow \frac{H_u^0}{\sqrt{Z_{H_u}}} ; & H_d^0 &\leftarrow \frac{H_d^0}{\sqrt{Z_{H_d}}}
\end{align*}
\]
(28)
and restore the appropriate dependence at the level of the pole-corrections.
3.3.2 Effective potential

After this discussion relative to the kinetic terms, let us turn to the Higgs potential. At tree-level, it is given by Eq. (27). Radiative corrections can be added to this picture by considering diagrams with vanishing external momenta or, equivalently, the Coleman-Weinberg formula for one-loop effects. In the $\overline{DR}$ scheme and the Landau gauge, the effective Higgs potential reads:

$$V_{\text{eff}}(H) = V_{H}^{\text{tree}}(H) + \delta V_{\text{eff}}(H) = \frac{1}{64\pi^2} \text{Tr} \left\{ C_\Phi M_\Phi^2 \left[ \ln \frac{M_\Phi^2}{Q^2} - \frac{3}{2} \right] \right\}$$

(29)

where the trace applies to all fields $\Phi$ of the model, with $C_\Phi$ depending on the Lorentz properties of $\Phi$ – respectively 1, 2, –2, –4, 3 for a real scalar, a complex scalar, a Majorana fermion, a Dirac fermion and a gauge boson – and $M_\Phi^2$ is the bilinear ('squared mass') matrix of the fields, where the dependence on Higgs fields has been kept.

Note that the gauge or $Z_3$ symmetries are still explicitly preserved by this potential (but not, in general, by its minimization). On the other hand, it involves terms of dimension $\geq 5$, so that expansions of the potential in the vicinity of its minimum will generically break the symmetries in an explicit way.

i) Minimization conditions and corrections to the mass matrices

The Higgs v.e.v.'s $v_u$, $v_d$, $s$ – of Eq. (27) – remember that we are considering the potential at the scale $Q$ – are now supposed to minimize the full potential of Eq. (29). Consequently, the minimization conditions of Eq. (11) (at tree-level) must be modified to account for the radiative effects. This provides the so-called tadpole equations:

$$\begin{align*}
\delta m^2_{H_u} &= -\frac{1}{2v_u} \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{\partial h^0_u / \sqrt{2}} \right\rangle \\
\delta m^2_{H_d} &= -\frac{1}{2v_d} \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{\partial h^0_d / \sqrt{2}} \right\rangle \\
\delta m^2_S &= -\frac{1}{2s} \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{\partial h^0_s / \sqrt{2}} \right\rangle \\
\delta \langle M_{H^\pm}^2 \rangle_{11} &= \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{\partial H_u \partial H_u^+} - \frac{1}{2v_u} \frac{\partial \delta V_{\text{eff}}}{\partial h^0_u / \sqrt{2}} \right\rangle \\
\delta \langle M_{H^\pm}^2 \rangle_{21} &= \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{\partial H_d \partial H_u^+} - \frac{i}{2v_d} \frac{\partial \delta V_{\text{eff}}}{\partial h^0_d / \sqrt{2}} \right\rangle \\
\delta \langle M_{H^\pm}^2 \rangle_{22} &= \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{\partial H_d \partial H_d^+} + \frac{i}{2v_d} \frac{\partial \delta V_{\text{eff}}}{\partial h^0_d / \sqrt{2}} \right\rangle \\
\delta \langle M_{H^0}^2 \rangle_{11} &= \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{\partial h^0_u / \sqrt{2}^2} + \frac{1}{2v_u} \frac{\partial \delta V_{\text{eff}}}{\partial h^0_u / \sqrt{2}} \right\rangle \\
\delta \langle M_{H^0}^2 \rangle_{22} &= \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{\partial h^0_d / \sqrt{2}^2} + \frac{i}{2v_d} \frac{\partial \delta V_{\text{eff}}}{\partial h^0_d / \sqrt{2}} \right\rangle \\
\delta \langle M_{H^0}^2 \rangle_{23} &= \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{\partial h^0_u \partial h^0_d / \sqrt{2}} \right\rangle \\
\delta \langle M_{H^0}^2 \rangle_{33} &= \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{(\partial h^0_u / \sqrt{2})^2} - \frac{1}{2} \frac{\partial \delta V_{\text{eff}}}{\partial h^0_u / \sqrt{2}} \right\rangle
\end{align*}$$

(31)

and for the neutral Higgs states:

$$\begin{align*}
\delta \langle M_{h}^2 \rangle_{11} &= \frac{1}{2} \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{(\partial h^0_u / \sqrt{2})^2} - \frac{1}{2v_u} \frac{\partial \delta V_{\text{eff}}}{\partial h^0_u / \sqrt{2}} \right\rangle \\
\delta \langle M_{h}^2 \rangle_{22} &= \frac{1}{2} \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{(\partial h^0_d / \sqrt{2})^2} - \frac{1}{2v_d} \frac{\partial \delta V_{\text{eff}}}{\partial h^0_d / \sqrt{2}} \right\rangle \\
\delta \langle M_{h}^2 \rangle_{23} &= \frac{1}{2} \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{\partial h^0_u \partial h^0_d / \sqrt{2}} \right\rangle \\
\delta \langle M_{h}^2 \rangle_{33} &= \frac{1}{2} \left\langle \frac{\partial^2 \delta V_{\text{eff}}}{(\partial h^0_u / \sqrt{2})^2} - \frac{1}{2} \frac{\partial \delta V_{\text{eff}}}{\partial h^0_u / \sqrt{2}} \right\rangle
\end{align*}$$

(32)

In other words, one recovers the tree-level squared mass matrix $\langle M^2 \rangle$ when replacing the Higgs fields by their v.e.v.'s in $M^2$. 

The notation $\langle f \rangle$ means that the function $f$ of the Higgs fields is evaluated at the Higgs v.e.v.'s.
This subroutine simply defines the tree-level mass matrices at the scale \(Q\) to the effective potential which are computed within our code.

The corrected Higgs masses are not the only information that we want to extract from the effective potential: the Higgs-to-Higgs couplings are also encoded within this formalism. Therefore, and for reasons that will become clear when we implement the various radiative contributions to the potential, we wish to match the full effective potential onto the following and simpler one:

\[
\delta \langle M_{H^0}\rangle_{44} = \frac{1}{2} \left( \frac{\partial^2 \delta V_{\text{eff}}}{(\partial \alpha_0^\prime)^2} - \frac{1}{\nu_d \alpha_0^\prime/\sqrt{2}} \partial \delta V_{\text{eff}} \right) \quad \delta \langle M_{H^0}\rangle_{45} = \frac{1}{2} \left( \frac{\partial^2 \delta V_{\text{eff}}}{(\partial \alpha_0^\prime)^2} - \frac{1}{\nu_d \alpha_0^\prime/\sqrt{2}} \partial \delta V_{\text{eff}} \right)
\]

This concludes the presentation of the general formalism and we may now describe the various contributions to the effective potential which are computed within our code.

\(\text{ii) miggstree\_CPV.}f\)

This subroutine simply defines the tree-level mass matrices at the scale \(Q\) according to Eqs.\(^{12}\) and \(^{13}\). However, the corrected Higgs masses are not the only information that we want to extract from the effective potential: the Higgs-to-Higgs couplings are also encoded within this formalism. Therefore, and for reasons that will become clear when we implement the various radiative contributions to the potential, we wish to match the full effective potential onto the following and simpler one:

\[
\delta \langle M_{H^0}\rangle_{44} = \frac{1}{2} \left( \frac{\partial^2 \delta V_{\text{eff}}}{(\partial \alpha_0^\prime)^2} - \frac{1}{\nu_d \alpha_0^\prime/\sqrt{2}} \partial \delta V_{\text{eff}} \right) \quad \delta \langle M_{H^0}\rangle_{45} = \frac{1}{2} \left( \frac{\partial^2 \delta V_{\text{eff}}}{(\partial \alpha_0^\prime)^2} - \frac{1}{\nu_d \alpha_0^\prime/\sqrt{2}} \partial \delta V_{\text{eff}} \right)
\]

\[
\delta \langle M_{H^0}\rangle_{15} = \frac{1}{2} \left( \frac{\partial^2 \delta V_{\text{eff}}}{(\partial \alpha_0^\prime)^2} - \frac{1}{\nu_d \alpha_0^\prime/\sqrt{2}} \partial \delta V_{\text{eff}} \right) \quad \delta \langle M_{H^0}\rangle_{24} = \frac{1}{2} \left( \frac{\partial^2 \delta V_{\text{eff}}}{(\partial \alpha_0^\prime)^2} - \frac{1}{\nu_d \alpha_0^\prime/\sqrt{2}} \partial \delta V_{\text{eff}} \right)
\]

\[
\delta \langle M_{H^0}\rangle_{26} = \frac{1}{2} \left( \frac{\partial^2 \delta V_{\text{eff}}}{(\partial \alpha_0^\prime)^2} - \frac{1}{\nu_d \alpha_0^\prime/\sqrt{2}} \partial \delta V_{\text{eff}} \right) \quad \delta \langle M_{H^0}\rangle_{35} = \frac{1}{2} \left( \frac{\partial^2 \delta V_{\text{eff}}}{(\partial \alpha_0^\prime)^2} - \frac{1}{\nu_d \alpha_0^\prime/\sqrt{2}} \partial \delta V_{\text{eff}} \right)
\]

\[
\delta \langle M_{H^0}\rangle_{36} = \frac{1}{2} \left( \frac{\partial^2 \delta V_{\text{eff}}}{(\partial \alpha_0^\prime)^2} - \frac{1}{\nu_d \alpha_0^\prime/\sqrt{2}} \partial \delta V_{\text{eff}} \right) + \frac{2\nu_u \partial \delta V_{\text{eff}}}{s^2 \nu_d \alpha_0^\prime/\sqrt{2}}
\]

This is a subset of the most general singlet + two doublet potential which one can write up to dimension 4 terms.\(^5\)

The gauge symmetry is observed. However the \(Z_3\)-symmetry only holds up to terms quadratic in the doublet fields and is explicitly broken by the terms in the last line of Eq.\(^{33}\). This potential is meant as an expansion of Eq.\(^{29}\) in the double fields and as we mentioned before, there is no reason why the \(Z_3\)-symmetry should hold in such an expansion. The characteristics of this potential are studied in appendix \(^E\) and matching the tree-level expression of Eq.\(^9\) is straightforward (see appendix \(^E.1\)).

\(\text{iii) mihiggsloop\_sferm\_CPV.}f\)

With this subroutine, we start adding radiative corrections to the effective potential, here those arising from SM-fermion and sfermion loops. These – particularly the contribution associated to the top – are known to convey the dominant radiative effect and lead e.g. to a substantial shift of the squared-mass of the SM-like Higgs boson.

The corresponding one-loop effects to the neutral Higgs mass matrix are particularly easy to include in the Coleman-Weinberg formalism of Eq.\(^{29}\) since the bilinear terms provide relatively simple matrices (refer to the box).\(^6\)

\(\text{Note however that we do not give more precisions about } V_0(|S|^2). \text{ If only terms of dimension } \leq 4 \text{ are kept, then the only choice would be } V_0(|S|^2) = K^2|S|^4. \)

\(^5\)Note however that we do not give more precisions about \(V_0(|S|^2)\). If only terms of dimension \(\leq 4\) are kept, then the only choice would be \(V_0(|S|^2) = K^2|S|^4\).
appendices B.1.1 and B.1.3. The details of the corrections are developed in the appendices D.2.1 and D.2.3. Note that we recover Eqs. (C16-18) of [6] in the CP-conserving limit.

The situation is slightly more complex for the charged Higgs as well as for the Higgs-to-Higgs couplings: we then decide to expand the potential in terms of the doublet fields, up to quartic order $H^4$ and match the corresponding expansion onto the simplified potential of Eq. 33. This amounts to an expansion in $v/M_{\mathrm{SUSY}}$, where $M_{\mathrm{SUSY}}$ here stands for any sfermion mass. The sfermion contributions to the coefficients of Eq. 33 are also provided in appendix D.2.3. Note that this alternative approach allows for a numerical cross-check with the corrections applied to the mass matrix of the neutral Higgs states with the method described in the previous paragraph.

In addition to these one-loop effects, the subroutine mhiggsloop_sferm_CPV.f also includes two-loop effects of order $\mathcal{O}(Y_t^4, Y_b^4, \alpha_S)$ leading to a product of large logarithms in the fermion sector: given that we are working at the average scale of squark masses, the squarks are assumed to give subleading contributions. On the other hand, effects associated to SM fermions and gauge bosons will not introduce any additional dependence on the new physics phases. The corresponding effects are implemented in the approximations of $\mathcal{O}(\mathcal{O}(Y_t^2, Y_b^2, \alpha_S)$ – see also Eq. (C.19) of [6], i.e. only the contributions to the quartic doublet parameters $\lambda_d$ and $\lambda_{\tilde{q}}$ of Eq. 33 are included – note that contributions to $M_Z^2$ or $M_H^2$ leave the analysis unaffected while contributions to e.g. $A_{\tilde{q}d}$ can be absorbed in a shift of the tree-level term $A_{\lambda_d}$, hence only drive a displacement in the parameter space. While these contributions are of two-loop order, they may still affect the mass of the SM-like Higgs state by several GeV, which is why we include them. Comparisons to more- elaborate two-loop calculations show that this approximation works well numerically (at the GeV level).

iv) mhiggsloop_inos_CPV.f

The next subroutine implements the radiative effects associated to charginos and neutralinos. Sticking to the Coleman-Weinberg approach, we consider the $9 \times 9$ bilinear term associated with gauginos and higgsinos (refer to appendix D.2.4). Due to the large rank of this matrix, we exclusively employ the method which consists in expanding the potential and matching it to the simplified version of Eq. 33. The corresponding results are collected in appendix D.2.4. Note that they differ from e.g. Eq. (C.22-24) of [6] where additional simplifying assumptions had been made.

v) mhiggsloop_gaugehiggs_CPV.f

The contributions of the electroweak gauge bosons to the Higgs potential seem easy to include in the Landau gauge: see appendix D.2.2. Yet the drawbacks of the Landau gauge are felt in the Higgs sector, where one then has to handle massless Goldstone bosons. The associated infrared divergences are of course purely spurious and disappear once confronted to momentum-dependent corrections, as already noted in [23]. Still it remains a technical issue to manipulate with caution. Moreover, the strategy consisting in diagonalizing the field-dependent bilinear matrices, which we have been employing until here, becomes impractical, even in an expansion in terms of the doublet fields, due to the large number of parameters and operators involved in the Higgs bilinear terms. Instead, we decide to employ the concurrent strategy in Higgs-mass calculations, which simply consists in a direct diagrammatic evaluation of the Higgs self-energies and tadpoles generated by Higgs loops. Nevertheless, disentangling the Higgs and gauge contributions in this approach proves quite artificial so that we will lead the calculation for both types of particles appearing in the loop at the same time.

Explicit expressions for the gauge and Higgs one-loop contributions to the Higgs self-energies and tadpoles are summarized e.g. in [20] or [24] (with different conventions for the loop functions), in the context of the MSSM, and the NMSSM differs only in the definition of the couplings and the presence of the singlet fields, hence leads to a formally comparable result. We choose to work in the Feynmann gauge as it is then possible to set the external momentum to 0 without generating IR-divergent logarithms. Indeed, we still aim at computing, not only the corrections to the Higgs masses, but also to the Higgs-to-Higgs couplings. For this, we proceed in the following fashion: after the radiative corrections to the Higgs mass matrices are evaluated at zero momentum, we subtract the pure-gauge contribution in the Landau gauge (for which we already know the potential from appendix D.2.2). The remaining ‘Higgs’ contributions to the mass matrices can then be identified with those that a $Z_3$-conserving renormalizable potential would produce, allowing for a reconstruction of the corrections to the $Z_3$-conserving parameters of the potential: this procedure is described for the CP-conserving case in [25] and is straightforwardly generalized to the CP-violating case. Of course, we then miss contributions to the $Z_3$-violating parameters (the last line of Eq. 33) but, as discussed in [25], these are subleading in the leading-logarithmic approach. Further details can be found in appendix D.2.5.

This completes the list of radiative contributions implemented in the effective potential.

---

6 The conventions $O(Y_t^4, Y_b^4, \alpha_S)$ or $O(\alpha_t^4, \alpha_b^4)$ are also used in the literature.

7 Note that, while the parameters of the effective potential will then receive contributions which are valid only at leading logarithmic order, this is not the case for the contributions to the Higgs masses since they are obtained directly from the diagrammatic calculation.
3.3.3 Pole corrections

The operations described in the previous lines have provided us with mass matrices for the Higgs states where radiative corrections from the potential (i.e. at zero external momentum) have been included. We will now detail how we account for momentum-dependent corrections. These calculations are conducted in the subroutine mhiggsloop_pole_CPV.f.

First, let us remind the reader that the radiative effects associated with non vanishing external momentum have been partially encoded into the wave-function scaling factors of paragraph 3.3.1. It is necessary to rescale the Higgs mass-matrices in order to account for the re-scaling of the Higgs fields:

\[
\left\langle M_{H^\pm}^2 \right\rangle_{ij} \leftarrow \frac{1}{\sqrt{Z_{H^\pm}Z_{H^\pm}^{-1}}} \left\langle M_{H^\pm}^2 \right\rangle_{ij} \quad ; \quad \left\langle M_{H^0}^2 \right\rangle_{ij} \leftarrow \frac{1}{\sqrt{Z_{H^0}Z_{H^0}^{-1}}} \left\langle M_{H^0}^2 \right\rangle_{ij}
\]

A \(\beta\)-angle rotation in the pseudoscalar and charged sector allows to rotate away the Goldstone bosons, leaving us with a 5 \(\times\) 5 symmetric mass matrix \(\left\langle M_{H^0}^2 \right\rangle_{ij}\) for the neutral sector and a \(\overline{D}\overline{F}\) squared-mass for the charged Higgs \(m^2_{H^\pm}\). \(\left\langle M_{H^0}^2 \right\rangle\) is now diagonalized according to Eq.14 providing us with corrected \(\overline{D}\overline{F}\) squared-masses for the neutral Higgs, \(m^2_{H^0}\), and their rotation matrix \(X^{H^0}\).

We then apply pole corrections to the \(\overline{D}\overline{F}\) squared-masses in order to evaluate the pole masses:

\[
\begin{align*}
    m_{H^0}^2 &= m^2_{H^0} + \left(1 + \sum_j \delta Z_{H^0} X^{H^0}_{ij}\right) - \left[\Pi_{H^0 H^0}(p^2 = m_{H^0}^2) - \Pi_{H^0 H^0}(p^2 = 0)\right] \\
    m_{H^\pm}^2 &= m^2_{H^\pm} + \left(1 + \sum_j \delta Z_{H^\pm} \cos^2 \beta + \delta Z_{H^\pm} \sin^2 \beta\right) - \left[\Pi_{H^\pm H^\pm}(p^2 = m_{H^\pm}^2) - \Pi_{H^\pm H^\pm}(p^2 = 0)\right]
\end{align*}
\]

While ideally the Higgs self energies \(\Pi_{H^0 H^0}(p^2)\) and \(\Pi_{H^\pm H^\pm}(p^2)\) should be evaluated at the pole masses, we approximate the latter by the \(\overline{D}\overline{F}\) masses. The full one-loop pole-corrections are applied. Shifts of the wave-function scaling factors \(\delta Z_{H^0, H^\pm, H^\pm}\) are known from Eqs.23-25. The shifts in the Higgs self energies are provided in appendix D.4.

This concludes our evaluation of the masses in the Higgs sector. We now wish to comment briefly on the precision achieved in this calculation. For this, it is instructive to consider the impact of the one-loop corrections with respect to the situation at tree-level. For mostly-doublet states, the leading effect is driven by the top-quark loop and, respectively to the tree-level mass \(m_H\), can be quantified as \(\sim \frac{N_c Y^2 m_t^2}{m_H^2} \ln \frac{m_t^2}{M_Z^2}\). Assuming that \(Q = O(\text{TeV})\), this amounts to a correction at the percent level for \(m_H = O(\text{TeV})\), but reaching a magnitude of \(\sim 100\%\) for \(m_H = O(100\text{ GeV})\): this accounts for the well-known sensitivity of the SM-like Higgs mass to radiative corrections. Contributions at the two-loop order will involve the strong coupling \(g_S\), or the top Yukawa coupling again, multiplying logarithms of a similar magnitude, so that the typical effect would easily amount to \(\sim 30\%\) of the one-loop contribution. Now, considering that we have included the leading double-logarithmic effects in the calculation, we can estimate a reduced uncertainty from higher orders, say at the level of \(\sim 10\%\) of the one-loop corrections. For a Higgs mass at \(\sim 125\text{ GeV}\), this still amounts to an uncertainty of several GeV. For a state at \(m_H = O(\text{TeV})\), this reduces to the percent level. The latter accuracy is treacherous however, as other sources of uncertainty appear e.g. in the determination of the couplings or neglected electroweak corrections entering the definition of the Higgs v.e.v.’s. In the outcome, the precision on the Higgs masses should not improve on \(O(1\%)\) for heavy doublet states. Corrections to singlet states are typically smaller, since the associated couplings \(\lambda, \kappa\) are of order \(\lesssim O(0.1)\) and the hierarchies between Higgs bosons and higgsinos may not be as large as those between SM fermions and sfermions. However, when the singlets mix significantly with doublet states, they will correspondingly acquire part of the larger uncertainties on doublet masses.

3.4 Couplings, decays and constraints

After the previous subroutines are run, one has a complete set of corrected masses and rotation matrices at one’s disposal. The following move consists in confronting this spectrum to physical processes.

3.4.1 Supersymmetric and Higgs couplings

The couplings of supersymmetric particles and Higgs bosons can take somewhat lengthy expressions. We thus design two subroutines, susycoup_CPV.f and higgscoup_CPV.f, in order to evaluate and store them within the code:
• The couplings of charginos / neutralinos to sfermions and SM fermions are implemented according to the formulae of appendix [B.3.1] and [B.3.2] for the three generations (still neglecting the Yukawa couplings of the two first generations).

• The trilinear couplings of the Higgs bosons to sfermions are computed after the results of appendix [B.2.3].

• The couplings of the Higgs bosons to charginos and neutralinos are also included as presented in appendix [B.2.3].

• Finally, we calculate corrected $\overline{DR}$ Higgs-to-Higgs couplings where radiative effects from sfermions, charginos, neutralinos and Higgs bosons are obtained from the simplified effective potential of Eq.[33] relevant formulae are provided in appendix [D.1]. Corrections from fermionic and gauge loops are explicitly incorporated as given in appendix [D.2.1] and [D.2.2]. The Yukawa and gauge couplings employed here have been run to the scale given by mass of the neutral Higgs state with first index in the coupling.

Note that the rescaling of Higgs fields in Eqs.[26] and [28] is also accounted for when computing the couplings of Higgs bosons.

3.4.2 Higgs and top decays

We then adapt the existing NMSSMTools subroutines decay.f and tdecay.f – respectively computing the Higgs and top two-body decays in the CP-conserving NMSSM – to the CP-violating case.

The subroutine hidecay_CPV.f calculates the Higgs widths and the dominant branching ratios. The following decay channels are considered:

• decays into a pair of SM fermions: $S_i^0 \rightarrow \mu^+\mu^-, \tau^+\tau^-, s\bar{s}, c\bar{c}, b\bar{b}, t\bar{t}; H^+ \rightarrow \mu^+\nu_\mu, \tau^+\nu_\tau, u\bar{s}, u\bar{b}, c\bar{s}, c\bar{b}, t\bar{b};$

• decays into (on-shell) gauge bosons: $S_i^0 \rightarrow WW, ZZ, \gamma\gamma, Z\gamma, gg;$

• decays into one Higgs and one gauge boson: $S_i^0 \rightarrow ZS_j^0, W^\pm H^\mp; H^+ \rightarrow W^+S_j^0;$

• Higgs-to-Higgs decays: $S_i^0 \rightarrow S_j^0S_k^0, H^+H^-;$

• supersymmetric decays: $S_i^0 \rightarrow \chi_j^+\chi^-_k, \chi_j^0\chi^-_k, \tilde{F}_j^\pm\tilde{F}_k^-; H^+ \rightarrow \chi_j^+\chi^-_k, \tilde{F}_j^+\tilde{F}_k^-.$

In the subroutine tdecay_CPV.f, we compute the following top decays: $t \rightarrow W^+b, H^+b, \tilde{T}_\chi^0.$ As in the original CP-conserving version, leading QCD corrections have been taken into account.

3.4.3 Phenomenological tests

We finally propose several tools to confront the CP-violating NMSSM spectrum to experimental constraints.

checkin_CPV.f compares the value of the neutral effective potential at the electroweak symmetry-breaking minimum with that at other points, e.g. for vanishing v.e.v.’s. Loop effects from the SM fermions and gauge bosons are included explicitly in this evaluation, while other radiative effects are encoded within the approximate potential of Eq.[33]. We also vary the dynamical phases and check whether this generates a deeper minimum. Finally, the minimization conditions of Eq.[11] and [30] are calculated explicitly, which allows e.g. to test the naturalness of the squared masses $m^2_{\tilde{H}_{i\neq 0}}$ of the potential: they should remain of the order of the SUSY-breaking scale.

In constsusypart_CPV.f, we generalize to the CP-violating case LEP limits on superparticle searches that were included in NMSSMTools for the CP-conserving case:

• test on chargino, slepton, gluino and squark masses;

• limits on $\tilde{T} \rightarrow bl\tilde{N}, \tilde{T} \rightarrow c\chi^0, \tilde{B} \rightarrow b\chi^0;$

• constraint on the invisible $Z$-width and neutralino-pair production.

HBNMSSM_CPV.f converts our spectrum into input for HiggsBounds [18] and HiggsSignals [19]. This allows to test the Higgs sector in view of LEP, TeVatron and LHC results via a call to the subroutines included within these public tools – note that NMSSMTools, HiggsBounds and HiggsSignals must be interfaced to make use of this subroutine. The chosen input mode is that employing effective couplings (see the documentation in [18]). Additional widths and branching ratios are taken from the results in hidecay_CPV.f and tdecay_CPV.f. In the 8Note that the decays into off-shell gauge bosons have not been included.
following section, we will be using the current versions HiggsBounds_4.2.0 and HiggsSignals_1.3.1, which incorporate all the experimental results released till december 2014. The default uncertainty on the Higgs mass precision is set to 3 GeV and modeled as a gaussian distribution.

We also include an alternative set of tests for the Higgs sector, based on the original subroutines of NMSSMTools. These collect:

- LEP_Higgs_CPV.f: LEP limits applying on neutral Higgs bosons produced in association with $Z's - e^+e^- \rightarrow Z* \rightarrow S_0^1 Z$ or in pairs $e^+e^- \rightarrow Z* \rightarrow S_0^1 S_0^1$ \[26\];
- TeVatron_CHiggs_CPV.f: TeVatron limits applying on a charged Higgs boson produced in top decays \[27\];
- bottomonium_CPV.f: test for a light mostly CP-odd Higgs in bottomonium decay – based on \[28\];
- LHC_Higgs_CPV.f: the inclusion of LHC limits on neutral or charged Higgs searches as well as the confrontation to the signals at $\sim 125$ GeV – after \[29\] – are in progress.

Note that these routines will not be used in the next section, as we will employ the currently more complete set of tests performed by HiggsBounds and HiggsSignals.

Finally, we design a subroutine EDM_CPV.f to estimate the electric dipole moments of the electron, the thallium atom, the neutron and the mercury atom. We essentially follow the summary in \[30\] – in the context of the MSSM; see also \[31\] for a recent work in the NMSSM. The supersymmetric one-loop effects are mediated by charginos, neutralinos or gluinos and sfermions. Moreover the two-loop diagrams of the Bar-Zee type – involving a fermion or sfermion loop connected to the quark / electron line by a Higgs and a photon propagator – are known to convey a sizable effect: these are particularly sensitive to the phases appearing in the Higgs sector. Other contributions, mediated by dimension 6 operators, are included as well. We estimate the associated uncertainties by adding linearly a 10% error on effects involving no coloured particles and a 30% error on contributions involving the coloured sector. Additional uncertainties associated to scale-running or hadronic parameters are also incorporated.

4 A few applications

We shall now make use of the subroutines which we have just presented and study phenomenological effects associated with the CP-violating NMSSM. This will be the opportunity to test our tool and compare its predictions with existing results.

4.1 CP-conserving limit

Setting all the phases to zero, it is possible to consider the CP-conserving case: in particular this allows to study how our results connect to the precision calculations implemented within NMSSMTools. Given that the input is common, discrepancies directly give an insight on the differences of treatment and the numerical magnitude of the corresponding effects.

i) Higgs spectrum

We shall first consider the Higgs masses. NMSSMTools provides three levels of precision in the inclusion of the radiative corrections to the $Z_3$-conserving Higgs sector:

- ‘Precision 0’: the default one – essentially following the procedure described in appendix C of \[6\] – confines to leading logarithmic order. Momentum-dependent effects are taken into account only to the extent of wavefunction renormalization (where the implementation is slightly different from ours: remember the discussion in section 3.3.1) and pole-corrections associated with the SM-fermion sector.
- ‘Precision 1’: a full one-loop + leading two-loop (to order $O(Y_4^{t,b,\alpha_S})$) implementation without momentum-dependent effects.
- ‘Precision 2’: a full one-loop + leading two-loop (to order $O(Y_4^{t,b,\alpha_S})$) implementation including momentum-dependent effects. It follows the work of \[32\].

Formally, our implementation – full one-loop including momentum-dependent corrections + leading two-loop double logarithms of order $O(Y_4^{t,b,\alpha_S})$ – should fall somewhere between these three procedures in terms of precision.

We first test our results in a region of the parameter space where $\kappa = 0.45$, $\tan \beta = 8$, $\mu_{\text{eff}} = 125$ GeV, $M_A = 1$ TeV, $A_\kappa = -288$ GeV, $m_{\tilde{T},\tilde{B}} = 1$ TeV, $m_{\tilde{U},\tilde{D}} = 1.5$ TeV, $m_{\tilde{L},\tilde{E}} = 200$ GeV, $2M_1 = M_2 = M_3/3 = 0.5$ TeV,
Figure 1: General aspect of the Higgs spectrum in the NMSSMTools procedures with precision 0 (upper left), precision 1 (upper right) and precision 2 (down left-hand) and in ours (dotted lines). λ ∈ [0, 0.65], tan β = 8, μ_{eff} = 125 GeV, M_A = 1 TeV, A_κ = -288 GeV, m_{\tilde{f}, \tilde{B}} = 1 TeV, m_{\tilde{U}, \tilde{D}} = 1.5 TeV, m_{\tilde{L}, \tilde{E}} = 200 GeV, 2M_1 = M_2 = M_3/3 = 0.5 TeV, A_t = -2 TeV, A_{b, \tau} = -1.5 TeV. In the down right-hand plot, the singlet composition S_{i3} of the two lightest CP-even states is displayed for precision 0 (green solid lines), precision 2 (blue solid lines) and for our calculation (dotted lines).

A_t = -2 TeV, A_{b, \tau} = -1.5 TeV and we scan over λ ∈ [0, 0.65]. The Higgs masses are displayed in Fig. 1 and the results of NMSSMTools for precision ‘0’ (greenish colors), ‘1’ (pink colors) and ‘2’ (bluish colors) are shown as solid lines while our calculation corresponds to the dots (yellow to red tones). We observe a significant variation of the masses corresponding to the mostly-singlet states while the doublet masses are grossly constant with varying λ. A typical NMSSM effect develops when singlet masses are close to doublet masses, as significant mixing may appear. In particular, when the singlet state is slightly lighter than the doublet one, the mixing tends to uplift the mass of the mostly-doublet Higgs. This is what occurs in this example for the CP-even sector in the upper range of λ. In Fig. 1, we see that our results fit quite closely the predictions of the procedure with precision 2, while larger discrepancies appear with respect to precision 0, especially at large λ.

Fig. 2 allows for a closer comparison among Higgs masses. For the Higgs states with mass close to ∼ 125 GeV (upper left-hand quadrant), we note a remarkable agreement between our calculation and the masses obtained with the precision setting 2, while the results obtained with precision 0 are about 2 GeV off: this fact should not make us forget that the uncertainties affecting the Higgs mass computations (also in the setting of precision 2) are...
of the order of several GeV. However, it justifies the observation that the leading two-loop effects are captured by the simpler inclusion of double logarithmic terms.

Concerning the heavy mass states, we observe in Fig.2 – in the upper-right and lower-left hand quadrants – that our results are intermediary between the calculations with precision 0 and precision 2. However, we note that the leading difference with precision 2 originates in the implementation of the wave-function scaling factors. Indeed, if we set the ‘Z-factors’ to 1 and modify the pole-corrections accordingly, we observe that our result – corresponding to the khaki dots in the lower-right-hand corner of Fig.2 – then matches that with precision 2 somewhat more closely (at the permil level). It is quite easy to see how the discrepancy develop between these two procedures. For this, let us focus on the CP-odd doublet state, where we will neglect the mixing with the singlet. In the case where the wave-function scaling factors are set to 1, the squared mass of this state is schematically: the effect of potential and pole corrections are encoded as $\delta_{\text{pot}},\delta_{\text{pole}}$ – obtained as (all the $p^2$-dependent terms are treated as
Figure 3: Higgs spectrum for $\lambda = 0.7$, $\kappa = 0.1$, $\tan \beta = 2$, $M_A \simeq 2.33 \mu_{\text{eff}} + 20.45 \text{ GeV}$, $M_A \in [0.3, 3] \text{ TeV}$, $A_\kappa = -50 \text{ GeV}$, $m_{\tilde{t}, \tilde{b}, \tilde{\tau}} = 0.5 \text{ TeV}$, $m_{\tilde{L}, \tilde{E}} = 1.5 \text{ TeV}$, $m_{\tilde{L}, \tilde{E}} = 110 \text{ GeV}$, $2M_1 = M_2 = 150 \text{ GeV}$, $M_3 = 1.5 \text{ TeV}$ $A_{t, b, \tau} = -0.1 \text{ TeV}$. Comparison of our results (dots) with precision 0 (upper left-hand plot), precision 2 (upper right-hand plot). Focus on the masses close to 125 GeV (bottom left-hand plot). Finally, results obtained with HiggsBounds and HiggsSignals.

pole corrections):

$$m^2_{\lambda_1} |_{\text{no } Z} = \lambda s [A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_\kappa) + \delta^\text{out}] \left( \frac{v^2_u}{v^2_d} + \frac{v^2_d}{v^2_u} \right) (1 + \delta^\text{pole})$$

(36)

In the approach where the wave-function scaling factors are taken into account at the level of the kinetic terms, the Z-factors intervene in the calculation at several steps: first, for the scaling of the v.e.v.'s, which transforms the tree-level mass-matrix in the CP-odd doublet sector to:

$$\lambda s \frac{\lambda s}{\sqrt{Z_S}} \left( A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_\kappa) \right) \left( \sqrt{\frac{Z_{H_u}}{Z_{H_d}} \frac{v_u}{v_d}} \right) \left( \frac{1}{\sqrt{\frac{Z_{H_u}}{Z_{H_d}} \frac{v_u}{v_d}}} \right)$$

(37)

The scaling effect on the potential corrections can be neglected as being of higher order. Then comes the scaling of the mass-matrix:

$$\frac{\lambda s}{\sqrt{Z_S} Z_{H_d}} \left( A_\lambda \cos \varphi_1 + \kappa s \sqrt{Z_S} \cos(\varphi_\lambda - \varphi_\kappa) + \delta^\text{out} \right) \left( \frac{v_u}{v_d} \right) \left( \frac{1}{\sqrt{\frac{v_u}{v_d}}} \right)$$

(38)
so that we can extract the $\mathcal{D}\Phi$ squared mass for the physical state via a $\beta$-angle rotation. Finally, the $Z$-factors have to be subtracted from the pole corrections, since they have been accounted for elsewhere. This provides:

$$m_A^2 \big|_Z = \frac{\lambda_3}{\sqrt{Z_S Z_{H_u} Z_{H_d}}} \left[ A_\lambda \cos \phi_1 + \frac{\kappa_S}{Z_S} \cos(\phi_\lambda - \phi_\kappa) + \delta_{\text{pole}} \right] \pm \sqrt{\frac{\delta_{\text{pole}}^2 + \cos^2(\beta(\lambda_{H_u} - 1) + \sin^2 \beta(\lambda_{H_d} - 1))}{\alpha_{\mu,\nu}} \left[ 1 + \delta_{\text{pole}} + \cos(2\delta Z_{\lambda_{H_u}} - 1) + \delta Z_{\lambda_{H_d}} \right]}$$

(39)

Expanding the $Z$-factors as $Z = 1 + \delta Z$, we see that Eqs. (36) and (39) differ by a factor $1 - \frac{\delta Z_{\lambda_{H_u}}}{2} + \frac{\delta Z_{\lambda_{H_d}}}{2}$. This explains the mismatch, reaching the order of one-loop effects, that is $O(1\%)$ here. In particular, the steeper apparent slope with varying $\lambda$, in Fig.2 is largely driven by the $Z_S$ factor. In principle, the approach including the wave-function scaling factors is the most refined among the two methods, hence should be preferred. On the other hand, our choice of setting the $Z$-factors at a low-value of the external momentum, $\mu_H = 125$ GeV, is not optimized for heavy states. In any case, a $1\%$ effect should not be taken too seriously in view of the various additional sources of uncertainty (parametric errors, running, etc.).

We then consider a second example with $\lambda = 0.7$, $\kappa = 0.1$, $\tan \beta = 2$, $\mu_{\text{eff}} \simeq 2.33 M_A + 20.45$ GeV, $M_A \in [0.3, 3]$ TeV, $A_\kappa = -50$ GeV, $m_{\tilde{T}, \tilde{B}} = 0.5$ TeV, $m_{\tilde{U}, \tilde{D}} = 1.5$ TeV, $m_{\tilde{L}, \tilde{E}} = 110$ GeV, $2 M_1 = 2 M_2 = 150$ GeV, $M_3 = 1.5$ TeV, $A_{L, U, D} = -0.1$ TeV. The results are displayed in Fig.3. This region of the parameter space highlights another effect in the NMSSM Higgs sector, namely the large contribution of $F$-terms to the mass of the SM-like state for large $\lambda$ and low $\tan \beta$. Indeed, the low value of $\tan \beta$, the low mass of the squarks of third generation and the moderate trilinear soft terms would result in a Higgs mass below $120$ GeV: this is a consequence of the specific tree-level contributions to the Higgs masses, associated with $\lambda$. Comparison of our results with the masses obtained with NMSSMTools for precision settings 0 and 2 again show that our calculation is typically closer to precision 2, although the differences are larger than in the previous scan (about 1 GeV for the two light CP-even states, as can be observed on the plot on the lower left-hand corner). We also display the output of HiggsBounds and HiggsSignals for our results (plot on the lower right-hand side): HiggsBounds exclusions apply e.g. in the presence of very light Higgs-states with non-vanishing doublet composition. The $\chi^2$ test of HiggsSignals provides values down to $\chi^2 \sim 75$ – for comparison, we obtain $\chi^2 \sim 78$ in the SM limit – when a light doublet is present close to $\sim 125$ GeV.

ii) Higgsino and gaugino masses

Our implementation of the chargino, neutralino and gluino masses should prove very similar to the original subroutines within NMSSMTools in the CP-conserving limit. Nevertheless, small technical differences should be noted:

- we take into account the Higgs-higgsino-singlino couplings which had been neglected in NMSSMTools: this results in additional corrections to the higgsino and singlino masses;
- similarly, bino and winos are not assumed degenerate in the calculation of loop corrections to the higgsino masses;
- all masses are chosen real and positive: this is possible since the diagonalizing matrices are complex. The convention in NMSSMTools consisted in keeping these matrices real, so that some masses could take negative values.

We consider the following region in the NMSSM parameter space: $\lambda = 0.55$, $\kappa = 0.45$, $\tan \beta = 12$, $\mu_{\text{eff}} \in [100, 1500]$ GeV, $M_A = 1$ TeV, $A_\kappa = -300$ GeV, $m_{\tilde{T}, \tilde{B}} = 1$ TeV, $m_{\tilde{U}, \tilde{D}} = 1.5$ TeV, $m_{\tilde{L}, \tilde{E}} = 200$ GeV, $2 M_1 = 2 M_2 = M_3/3 = 0.5$ TeV, $A_{L, U, D} = -1.5$ TeV. The masses of the higgsinos and gauginos are shown in Fig.3. The scan over $\mu_{\text{eff}}$ drives a significant variation of the higgsino masses, while the gaugino masses remain essentially constant. Once again, the masses obtained with the original routine of NMSSMTools are depicted with a solid line, whereas our results appear as dots: the general features are identical. More quantitatively, the main deviation reaches $\sim 3\%$ at the level of the neutralino masses: it originates from the corrections to the singlino mass, which were neglected in NMSSMTools. For the rest of the spectrum, e.g. the sfermion masses, our calculation reduces, in the CP-conserving limit, to the original implementation within NMSSMTools. Therefore, we will not push the comparison in this limit any further.

4.2 CP-violating case

CP-violation could induce several phenomenological effects at colliders. The most immediate one would be the measurement of EDM’s. The absence of any hint in corresponding searches thus places stringent limits on new-physics effects. However note that, at one loop order, these effects are essentially driven by the gaugino phases. In
other words, new-physics phases associated to the Higgs sector or the third generation sfermions enter the EDM’s at the two-loop level only and are thus more loosely constrained. CP-violation could also intervene in rare flavour decays and oscillations, which are consistent so far with the SM-interpretation (where only the CKM phase is present): such effects have not been included in our study yet and we will not discuss them here.

i) **CP-violating effects in the NMSSM Higgs spectrum**

CP-violation could enter the Higgs sector at tree-level, via a non-vanishing phase $\varphi_{\lambda} - \varphi_{\kappa}$, or at the loop-level, e.g. via the phases associated to the sfermions of third generation. As a first consequence, the neutral Higgs states would become scalar / pseudoscalar admixtures, which affects their couplings to SM particles: for doublet states, the pseudoscalar component does not couple to a $ZZ$ or $W^+W^-$ pair, so that the corresponding decay channels, as compared to the fermionic decays, are suppressed / enhanced with respect to the case of pure CP-even / CP-odd eigenstates. Other effects can be measured in the fermionic channels, provided, however, that the fermion masses are sufficiently large. Therefore the presence of CP-violation in the Higgs sector could be tested in precision analyses of the Higgs properties – for the observed or hypothetical new states. Note however that doublet Higgs states are typically shielded from CP-violating mixing – consider e.g. the zero-entries in the tree-level mass-matrix of Eq.13 –, so that only a very high degree of precision in the measurement of the branching ratios would be likely to detect the tiny – radiatively-generated – pseudoscalar component of a mostly CP-even state. Moreover, the current limits on Higgs searches tend to favour a sizable mass-hierarchy between the SM-like Higgs state and the approximately degenerate ‘heavy-doublet’ states. This makes the presence of a pseudoscalar doublet component within the observed Higgs state unlikely, as the mixing of this state with the ‘heavy-doublet’ pseudoscalar would

Figure 4: Higgsino / gaugino spectrum for $\lambda = 0.55$, $\kappa = 0.45$, $\tan \beta = 12$, $\mu_{\text{eff}} \in [100, 1500]$ GeV, $M_A = 1$ TeV, $A_\kappa = -300$ GeV, $m_{\tilde{f},\tilde{b}} = 1$ TeV, $m_{\tilde{U},\tilde{D}} = 1.5$ TeV, $m_{\tilde{L},\tilde{E}} = 200$ GeV, $2M_1 = M_2 = M_3/3 = 0.5$ TeV, $A_{t,b,\tau} = -1.5$ TeV. Comparison of our results (dots) with the implementation within NMSSMTools (solid lines; note that the masses have been taken in absolute value). The plot below shows the ratio between our results for neutralino masses and those delivered by NMSSMTools.

Figure 4: Higgsino / gaugino spectrum for $\lambda = 0.55$, $\kappa = 0.45$, $\tan \beta = 12$, $\mu_{\text{eff}} \in [100, 1500]$ GeV, $M_A = 1$ TeV, $A_\kappa = -300$ GeV, $m_{\tilde{f},\tilde{b}} = 1$ TeV, $m_{\tilde{U},\tilde{D}} = 1.5$ TeV, $m_{\tilde{L},\tilde{E}} = 200$ GeV, $2M_1 = M_2 = M_3/3 = 0.5$ TeV, $A_{t,b,\tau} = -1.5$ TeV. Comparison of our results (dots) with the implementation within NMSSMTools (solid lines; note that the masses have been taken in absolute value). The plot below shows the ratio between our results for neutralino masses and those delivered by NMSSMTools.
be suppressed in proportion to the large mass gap. Another test would involve the two ‘heavy-doublet’ neutral states, which are generically close in mass, so that their mixing could be significant. Yet, the detection of CP-violation there will still require high-precision experiments (and the discovery of these states), due to a typically reduced production cross-section – with respect to a SM Higgs boson at the same mass; this is related to the mostly $H_d$-nature of these states – as well as the opening of many less-controlled decays (e.g. towards new-physics states).

In the NMSSM, another type of CP-violating mixing is allowed: a mostly CP-odd singlet may mix with the doublet CP-even states – provided $\lambda$ and $\kappa$ are large and $\varphi_\lambda - \varphi_\kappa$ is non-vanishing – and this effect could be fairly important if these states are close in mass. In the following, we focus on the SM-like Higgs state at $\sim 125$ GeV. Such a scenario is studied in Fig.5 for $\lambda = 0.68, \kappa = 0.1, \tan \beta = 2, \mu_{eff} = 635$ GeV, $M_A = 1.5$ TeV, $A_\kappa = -100, 0, 10$ GeV, $m_{\tilde{T}, \tilde{B}, \tilde{\tau}} = 0.5$ TeV, $m_{\tilde{U}, \tilde{D}, \tilde{E}} = 1.5$ TeV, $2M_1 = M_2 = M_3/3 = 0.5$ TeV, $A_{t,b,\tau} = -0.1$ TeV. CP-violation is induced through variations of $\varphi_\kappa$: note that this strategy is the safest in view of the EDM’s, as non-vanishing $\varphi_\lambda$ produces direct CP-violation in the doublet higgsino sector (as well as in the sfermion sector). In the first column of Fig.5, $A_\kappa = -100$ GeV, and the mostly CP-odd state is relatively far in mass ($\sim 250$ GeV); correspondingly, the mixing with the SM-like state does not reach 1%. The latter state has a somewhat low mass of $\sim 121$ GeV which translates into a mediocre fit to

![Figure 5: Characteristics of the light Higgs states for $\lambda = 0.68, \kappa = 0.1, \tan \beta = 2, \mu_{eff} = 635$ GeV, $M_A = 1.5$ TeV, $A_\kappa = -100, 0, 10$ GeV, $m_{\tilde{T}, \tilde{B}, \tilde{\tau}} = 0.5$ TeV, $m_{\tilde{U}, \tilde{D}, \tilde{E}} = 1.5$ TeV, $2M_1 = M_2 = M_3/3 = 0.5$ TeV, $A_{t,b,\tau} = -0.1$ TeV. CP-violation is induced through variations of $\varphi_\kappa$: note that this strategy is the safest in view of the EDM’s, as non-vanishing $\varphi_\lambda$ produces direct CP-violation in the doublet higgsino sector (as well as in the sfermion sector). In the first column of Fig.5, $A_\kappa = -100$ GeV, and the mostly CP-odd state is relatively far in mass ($\sim 250$ GeV); correspondingly, the mixing with the SM-like state does not reach 1%. The latter state has a somewhat low mass of $\sim 121$ GeV which translates into a mediocre fit to...](image-url)
the LHC-observed signals, hence a high χ²-value with HiggsSignals. In the second column, we take \( A_κ = 0 \) GeV, so that the CP-odd singlet is close in mass to the SM-like state: at \( φ_κ = 0 \), the singlet has a mass of about \( \sim 115 \) GeV. Consequently, a significant mixing develops between the two light states as soon as \( φ_κ \neq 0 \), the effect reaching the level of 30 to 40%. A consequence is the uplift in mass of the heavier SM-like state so that the associated signal gives an improved fit with the LHC data. The column on the right is obtained for \( A_κ = 10 \) GeV: the CP-odd singlet is then somewhat lighter (\( \sim 100 \) GeV), so that the mixing effect at non-vanishing \( φ_κ \) remains milder than in the previous case, yet generates an uplift of the mass of the SM-like state as well. It is to be noted that the mostly CP-odd singlet acquires a CP-even doublet component which reaches \( O(10%) \): the latter would generate a signal at the \( O(10\%) \)-level as compared to a SM-like state at the same mass – indeed, the production cross-section at colliders is essentially mediated by the doublet components. For a state with mass \( \sim 100 \) GeV, the corresponding signal could be consistent with the LEP \( \sim 2.3 \) σ excess in Higgs searches with a \( b\bar{b} \) final state \[26\], even though the state is dominantly CP-odd.

![Figure 6: Branching ratios of the light Higgs states for \( A_κ = 10 \) GeV in the scan of Fig.5.](image)

Note that the two effects that we highlighted – uplift of the mass of the SM-like state via its mixing with the singlet and presence of a ‘miniature’ Higgs boson under 125 GeV – are well-known in the CP-conserving NMSSM \[7\], provided the auxiliary singlet is CP-even. CP-violation extends this possibility to CP-odd singlets. Further consequences appear on Fig.6 at the level of the branching fractions of the Higgs states – we display their values for the \( b\bar{b} , c\bar{c} \) and \( γγ \) final states – similarly to the case where the SM-like Higgs boson mixes with a CP-even singlet, the proportions among doublet components \( h_0^u \) and \( h_0^d \) may fluctuate, displacing the branching ratios. However, the main effect in Fig.6 concerns the rates of the lighter singlet state which become dominated by CP-even-like channels – for fermionic final states, rates differ at the radiative level depending on the CP property \[9\] –, while the fluctuations of the branching fractions of the mostly CP-even doublet are dominated by the variations of the associated Higgs mass.

Disentangling this scenario – where a light mostly CP-odd singlet mixes with the SM-like Higgs boson – from the CP-conserving one – where the light singlet-like state is genuinely CP-even – is likely to prove very difficult. The reason rests with the observation that the singlets do not lend specific properties to the SM-like Higgs state – they simply reduce its total width and might alter its branching ratios at the percent level. Moreover their decays are essentially mediated by the doublet component which they acquire in the mixing, i.e. a CP-even one in both cases. Typical singlet decays – towards hypothetically lighter singlet states or singlinos – would not necessarily help to discriminate among CP-even and CP-odd mixing and would be problematic in terms of compatibility with the measured Higgs signals. Indeed, the standard rates would then be suppressed in proportion of the magnitude of the unconventional decays. While deviations of the rates of the observed Higgs state from the standard ones might be interpreted via such a mixing effect – should such deviations be detected at the LHC or a future linear collider –, it is questionable anyway whether the light singlet could be detected – possibly in Higgs-pair production: see e.g. \[33\] in the CP-even case.

At the outcome of this discussion, we see that, while the CP-violating effects involving singlets in the Higgs sector may be larger than in the pure doublet case, they are also more difficult to trace and could be mistaken for CP-conserving phenomena. For this reason, it is essential that CP-violation be tested in processes where the CP-properties are well-controlled, which brings us back to EDM’s or rare flavour transitions. Spectral effects in the Higgs sector are unlikely to allow for discrimination with the CP-conserving case.

**ii) Comparison of the Higgs mass predictions with the existing literature**

We will now compare some of our results with existing analyses in the literature, where CP-violation has been considered. Note that, contrarily to the comparison with the calculations in the CP-conserving NMSSMTools, one
should not expect much more than a qualitative agreement. Indeed, diverging treatments in different tools, e.g. concerning the definition of the input – such as the choice of running Yukawa couplings or that of $A_\kappa$ versus $A_\kappa \cos \varphi_2$ – are known to lead to sizable deviations, already in the CP-conserving case. The level of precision in radiative corrections is also to be considered.

NMSSMCalC [14] is a public tool computing the Higgs spectrum and decays in the $Z_3$-conserving but possibly CP-violating NMSSM. The chosen approach is that of a diagrammatic calculation. The level of precision has recently been extended to include the dominant two-loop corrections [34].

Figure 7: Top: phase-dependence of the mostly $h_u^0$ Higgs state as obtained from section 4.1 of [34]. Below: estimates of the EDM’s (normalized by their experimental upper bounds: see text). The color coding follows that of Fig.6 of [34]: green for a scan over $\varphi_\mu$, red for a scan over $\varphi A_t$ and blue for a scan over $\phi_{M_3}$. When the blue curve does not appear, the reason is that associated values are negligibly small. Note that several estimates are employed for the neutron EDM.

First, we focus on the results of [34] dealing with CP-violating effects, i.e. essentially Fig.6 and the surrounding
text in that paper. If we blindly input the parameters given in section 4.1 of this reference into our framework\[10\], the spectrum — not unexpectedly and already with the CP-conserving \textsc{nmssmtools} — turns out to be slightly different from the quoted one: in particular, the mostly CP-even and mostly CP-odd singlet states appear with masses \( \sim 108 \text{ GeV} \) and \( \sim 113 \text{ GeV} \) respectively. Yet, this discrepancy can be absorbed within a small shift of \( A_{\kappa} \cos \varphi_{2} \): using the value 203 GeV, we then recover states at \( \sim 103 \) and \( \sim 128 \text{ GeV} \) so that the Higgs spectrum then largely coincides with the one provided in \[34\].

In any case, this manipulation has little effect on the properties of the mostly \( h_{0} \)-state, close to 125 GeV. Scanning over the phases \( \varphi_{A_{t}}, \varphi_{\mu} \) — in the notations of \[34\], this means a scan over \( \varphi_{\lambda} \), keeping \( \varphi_{\kappa} = \varphi_{\lambda} \) so that CP-violation does not enter the Higgs sector at tree-level — and \( \phi_{M_{3}} \), we obtain the plots of Fig.7. On the upper part, we observe that the general dependence of the ‘SM-like’ Higgs mass on \( \varphi_{A_{t}} \) and \( \varphi_{\mu} \) is largely reminiscent in shape and magnitude of that observed in Fig.6 of \[34\]. In these two cases, CP-violation enters the Higgs sector via radiative corrections, where the leading effect is generated by the sfermion corrections. On the other hand, the mass obtained with our code is independent from \( \phi_{M_{3}} \), while such a dependence already appears at one-loop in \[34\]. Note that one does not expect gluino corrections to the Higgs mass at one-loop order and it is thus not surprising that our implementation does not show any variation with \( \phi_{M_{3}} \). The corresponding effect in \[34\] is explained there as an artifact of the top-Yukawa \( \overline{\text{DR}} \) counterterm-fixing of higher order. Note also that the corresponding fluctuations, at the GeV level, are small compared to the uncertainty that one naively expects for the Higgs mass (a few GeV).

In addition, we show the values of the EDM’s that we obtain in these scans. These have been normalized by the experimental upper bounds: \( \sim 1 \cdot 10^{-28} \text{ e cm} \) for the electron \[35\] — estimate from thorium monoxide experiment \( \sim 1.3 \cdot 10^{-24} \text{ e cm} \) for the Thallium atom \[36\], \( \sim 3.1 \cdot 10^{-28} \text{ e cm} \) for the Mercury EDM \[37\] and \( \sim 3 \cdot 10^{-26} \text{ e cm} \) for the neutron \[38\]. Note that only the central values are displayed, without error bands. The color code is the same as in Fig.6 of \[34\], i.e. green for the scan on \( \varphi_{\mu} \), red for that on \( \varphi_{A_{t}} \), and blue for the one over \( \phi_{M_{3}} \) (when the curve does not appear in the plot, this is because the corresponding values are negligibly small). We see that the scan over \( \varphi_{\mu} \) may generate tensions with the EDM’s — mostly the electron EDM — when \( \varphi_{\mu} \) is not trivial.

![Figure 8: Masses and CP-even composition \((X_{1i}^{H_{0}^{\pm 2}} + X_{12}^{H_{0}^{\pm 2}} + X_{13}^{H_{0}^{\pm 2}})\) for the three lightest Higgs states in the scenario of section 4.1.1 of \[39\].](image)

We now turn to the one-loop analysis proposed in \[39\]. We first consider the scenario presented in section 4.1.1 of this reference, where CP-violation intervenes in the Higgs sector at tree-level via the phase \( \varphi_{\kappa} \). Again, a qualitatively close spectrum can be recovered with little alteration of the input proposed in the reference and our results are displayed in Fig.8 while small differences appear, both the Higgs masses and the composition of the states agree reasonably well with those of \[39\]. The major source of deviation is associated to the use of different input — \( A_{\kappa} \) in \textsc{nmssmcalc} instead of \( A_{\kappa} \cos \varphi_{2} \) in our case —, so that the comparison makes limited sense when \( \varphi_{2} \) becomes large (i.e. for \( \varphi_{\kappa} \sim \pi/8 \)). In the regime considered here, the CP-even and CP-odd singlet states are close

\[10\]Note that this addresses the \( \overline{\text{DR}} \)-parameters in the reference, since the parameters within \textsc{nmssmtools} are regarded as \( \overline{\text{DR}} \).
Figure 9: Masses in the scenarios of section 4.1.2 (scan over $\varphi_\mu \equiv \varphi_\lambda = \varphi_\kappa$) and section 4.1.3 (scan over $\varphi_{A_1}$) of [39].

in mass to the SM-like Higgs boson, so that the non-vanishing $\varphi_\kappa$ generates a substantial mixing of these three states.

[39] then considers the case where CP-violation is absent in the tree-level Higgs sector, but radiatively generated via phases in the supersymmetric spectrum. In the first case (section 4.1.2), the ‘active’ phase is $\varphi_\lambda$, but the condition $\varphi_\kappa = \varphi_\lambda$ ensures that no CP-violation enters the Higgs potential at tree-level – we will recycle the previous notation $\varphi_\mu$ for this scenario. In the second case, only the phase $\varphi_{A_1}$ is non-trivial. We display our results in Fig.9 and observe that they capture the effects depicted in Fig.5 and Fig.7 of [39].

Our code is thus able to reproduce the main qualitative features that were observed in the CP-violating case by NMSSMCALC analyses. We stress that a more quantitative study would have limited interest, as the divergent treatment of the input already generates discrepancies between the CP-conserving NMSSMTools and NMSSMCALC.

5 Conclusions

We have presented a series of Fortran tools extending NMSSMTools to the CP-violating case. Radiative corrections to the supersymmetric and Higgs masses are computed at one-loop order. Dominant two-loop effects to the Higgs masses are also included in the double-log approximation. Additionally, Higgs couplings and decays, as well as top two-body decays and EDM’s are implemented and allow for phenomenological tests of the spectra. We have shown that our code compares competitively with existing results, both in the CP-conserving and CP-violating cases. The new tools will be made publicly available on the NMSSMTools website [13] in the near future.

We also highlighted a scenario made possible by CP-violation, where the SM-like Higgs would mix with a mostly CP-odd singlet state. The consequences on the Higgs phenomenology are similar to the CP-conserving mixing with a light CP-even singlet so that both scenarios should prove difficult to discriminate, unless genuine CP-violating effects – e.g. in EDM’s or flavour physics – are discovered simultaneously.

Finally, we would like to close this discussion with some details concerning the future developments which we plan to consider. First, an extension of our tools including $Z_3$-violating terms should raise little difficulty. Then, flavour constraints are relevant in the CP-violating NMSSM and we intend to design phenomenological tests accordingly. Finally, the dominant two-loop corrections to the Higgs masses will be calculated in a more quantitative way.

\[ F_1(m^2, M^2) = \frac{1}{m^2 - M^2} \left[ m^2 \left( \ln \frac{m^2}{Q^2} - 1 \right) - M^2 \left( \ln \frac{M^2}{Q^2} - 1 \right) \right] \]
\[ F_3(m^2, M^2) = \frac{m^2 \left[ \ln \frac{m^2}{M^2} - 1 \right] + M^2}{(m^2 - M^2)^2} \]
\[ F_5(m_1^2, m_2^2, m_3^2) = \frac{m_1^2 m_2^2 \ln \frac{m_2^2}{m_1^2} - m_1^2 m_3^2 \ln \frac{m_3^2}{m_1^2} + m_2^2 m_3^2 \ln \frac{m_3^2}{m_2^2}}{(m_1^2 - m_3^2)(m_1^2 - m_2^2)(m_1^2 - m_3^2)} \]
\[ F_6(m_1^2, m_2^2, m_3^2) = \frac{m_1^2 \ln \frac{m_1^2}{m_3^2}}{(m_1^2 - m_3^2)(m_1^2 - m_2^2)(m_1^2 - m_3^2)} + \frac{m_2^2 \ln \frac{m_2^2}{m_1^2}}{(m_1^2 - m_3^2)(m_2^2 - m_3^2)} + \frac{1}{(m_1^2 - m_3^2)(m_2^2 - m_3^2)} \]
\[ F_7(m^2, M^2) = -\frac{m^2 \left[ \ln \frac{m^2}{M^2} - 2 \right] - M^2 \left[ \ln \frac{M^2}{m^2} - 2 \right]}{(m^2 - M^2)^3} \]

We only consider the finite part of the loop integrals:

\[ A_0(m) = -F_0(m^2) \]
\[ B_0(p, m, M) = -\int_0^1 \ln \frac{x m^2 + (1 - x)(M^2 - p^2) + (1 - x)^2 p^2}{Q^2} \, dx \]
\[ B_1(p, m, M) = \int_0^1 (1 - x) \ln \frac{x m^2 + (1 - x)(M^2 - p^2) + (1 - x)^2 p^2}{Q^2} \, dx \]

Finally, we borrow some of the notations of [24]:

\[ B_{FF}(p, m, M) = (p^2 - m^2 - M^2)B_0(p, m, M) - A_0(m) - A_0(M) \]
\[ B_{SV}(p, m, M) = -(2p^2 + 2m^2 - M^2)B_0(p, m, M) + A_0(m) - 2A_0(M) \quad \text{(Feynmann gauge)} \]

B The tree-level masses and couplings

This appendix provides the reader with a detailed presentation of the tree-level spectrum and couplings of the CP-violating, minimal-flavour-violating, R-parity and \( Z_3 \) conserving NMSSM.

B.1 Tree-level masses

Here we derive the tree-level bilinear terms of the lagrangian. For a later application to the Higgs couplings as well as to the loop-corrections in the Coleman-Weinberg effective potential, we will try to keep a full dependence in the Higgs scalar fields \( S, H_u = (H_u^0, H_u^o)^T \) and \( H_d = (H_d^0, H_d^o)^T \). To evaluate the masses, one of course simply needs to replace these fields by their v.e.v.’s.

B.1.1 SM fermions

The Higgs-fermion potential reads:

\[ V_f = -(H_u^0 d_L V_{CKM}^T - H_u^0 u_L)Y_u u_R^c + (H_d^0 d_L - H_d^0 u_L V_{CKM})Y_d d_R^c + (H_d^0 c_L - H_d^0 u_L)Y_e e_R^c + h.c. \] (40)
Focussing on the third generation (and neglecting off-diagonal CKM elements), we may cast under matrix form:

\[ V_f = (\bar{u}_L, u_R, \bar{d}_L, d_R) M_{q^3} \left( \begin{array}{c} u_L \\ \bar{u}_R \\ d_L \\ \bar{d}_R \end{array} \right) + (\bar{\nu}_L, \nu_R, e_L, e_R) M_{\nu^3} \left( \begin{array}{c} \nu_L \\ \bar{\nu}_R \\ e_L \\ \bar{e}_R \end{array} \right) \]

\[ M_{q^3} \equiv \begin{bmatrix} 0 & Y_t H_u^0 & 0 & -Y_b H_d^+ \\ Y_t^* H_u^0 & 0 & -Y_t H_u^+ & 0 \\ 0 & -Y_t H_u^- & 0 & Y_b H_d^0 \\ -Y_b H_d^- & 0 & Y_b H_d^0 & 0 \end{bmatrix} \quad ; \quad M_{\nu^3} \equiv \begin{bmatrix} 0 & 0 & -Y_e H_e^+ \\ 0 & 0 & Y_e H_e^- \\ -Y_e H_e^- & Y_e H_e^+ & 0 \end{bmatrix} \]

(from which we derive the squared-mass matrices:

\[ M_{q^3}^\dagger M_{q^3} = \begin{bmatrix} Y_t^2 |H_u^0|^2 + Y_t^2 H_d^+ H_d^- \\ 0 \\ -Y_b^2 H_u^0 H_d^- \\ 0 \end{bmatrix} \]

\[ M_{\nu^3}^\dagger M_{\nu^3} = \begin{bmatrix} Y_e^2 (|H_u^0|^2 + H_u^+ H_u^-) \\ 0 \\ 0 \\ Y_e^2 (|H_d^0|^2 + H_d^+ H_d^-) \end{bmatrix} \]

Replacing the Higgs fields by their v.e.v.’s, one obtains diagonal matrices \( M_{q^3}^2 \) and \( M_{\nu^3}^2 \), with the usual relations: \( m_t^2 = Y_t^2 v_t^2 \), \( m_b^2 = Y_b^2 v_b^2 \), \( m_\nu^2 = 0 \), \( m_\tau^2 = Y_e^2 v_e^2 \).

**B.1.2 Electroweak gauge bosons**

From the Higgs kinetic terms, one obtains the Higgs-gauge potential (where we omit the derivative Higgs couplings):

\[ V_G = \frac{1}{4} \left[ g^2 B_\mu B^\mu + g^2 \bar{W}_\mu \cdot \bar{W}_\mu \right] (|H_u^0|^2 + |H_d^0|^2) + \frac{gg'}{2} B_\mu \bar{W}_\mu \cdot \left( H_u^+ H_u^- - H_d^+ H_d^- \right) \]

After the fields are rotated to the mass-states,

\[ A_\mu \equiv \frac{g B_\mu + g' W_3^\mu}{\sqrt{g^2 + g'^2}} \quad ; \quad Z_\mu \equiv -\frac{g' B_\mu + g W_3^\mu}{\sqrt{g^2 + g'^2}} \quad ; \quad W_\pm = \frac{W_1^\mu \mp i W_2^\mu}{\sqrt{2}} \]

we derive:

\[ V_G = \frac{1}{2} (A_\mu, Z_\mu) \left[ \begin{bmatrix} 0 & 0 \\ \frac{g^2 + g'^2}{2} & \frac{g^2 g'^2}{2(g^2 + g'^2)} \end{bmatrix} \left( |H_u^0|^2 + |H_d^0|^2 \right) + \left( \frac{g^2 g'^2}{2(g^2 + g'^2)} \right) (H_u^+ H_u^- + H_d^+ H_d^-) \right] \left( \begin{array}{c} A^\mu \\ Z^\mu \end{array} \right) \]

\[ + \frac{g^2}{2} (|H_u^0|^2 + |H_d^0|^2) + H_u^+ H_u^- + H_d^+ H_d^-) W_\mu W_\mu^* \]

\[ + \frac{gg'}{2\sqrt{2} \sqrt{g^2 + g'^2}} (g A^\mu - g' Z^\mu) \left[ W_\mu^+ (H_u^0 H_u^- - H_d^0 H_d^-) + W_\mu^- (H_u^+ H_u^- - H_d^+ H_d^-) \right] \]

This leads to the usual gauge-boson masses: \( M_1^2 = 0 \), \( M_W^2 = \frac{g^2}{2} (v_u^2 + v_d^2) \), \( M_2^2 = \frac{g^2 + g'^2}{2} (v_u^2 + v_d^2) \).
B.1.3 Sfermions

The Higgs-sfermion potential originates from soft, \( F \) and \( D \) terms:

\[
V_F = m_Q^2 Q_L^i Q_L^i + m_U^2 U_R^i U_R^i + m_D^2 D_R^i D_R^i + m_L^2 L_L^i L_L^i + m_E^2 E_R^i E_R^i + \sum_{\alpha} H_u^\dagger D_L V_{\text{CKM}}^* Y_{\alpha} A e^{i \phi_{\alpha}} U_R^i + (H_d^0 D_L - H_d U_L V_{\text{CKM}}) Y_d A e^{i \phi_{\alpha}} D_R^i + (H_d^0 E_L - H_d^* N_L) Y_e A e^{i \phi_{\alpha}} E_R^i + h.c.
\]

\[
+ \left| (H_u^+ D_L V_{\text{CKM}}^* - H_u^0 U_L) Y_u \right|^2 + \left| Y_u V_{\text{CKM}} H_u^+ U_R - Y_d H_d^0 D_R^i \right|^2 + \left| Y_u H_u^0 U_R^i - Y_d H_d^0 V_{\text{CKM}}^* D_R^i \right|^2 + \left| (H_d^0 D_L - H_d U_L V_{\text{CKM}}) Y_d^2 + \left| (H_d^0 E_L - H_d^* N_L) Y_e^2 \right|^2 + \left| Y_e H_d^0 E_R^i \right|^2 + \left| \lambda e^{i \phi_{\alpha}} S H_u^+ - U_L V_{\text{CKM}} Y_d D_R^i - N_L Y_e E_R^i \right|^2 + \left| \lambda e^{i \phi_{\alpha}} S H_d^+ - U_L Y_d U_R^i \right|^2 + \left| \lambda e^{i \phi_{\alpha}} S H_d^+ - D_L V_{\text{CKM}}^* Y_u U_R^i \right|^2
\]

\[
+ \left( \frac{g^2}{8} \right) \left| H_u^+ H_u - H_d^\dagger H_d + \frac{1}{3} Q_L^i Q_L^i - \frac{4}{3} U_R^i U_R^i + \frac{2}{3} D_R^i D_R^i - L_L^i L_L^i + 2 E_R^i E_R^i \right|^2
\]

The bilinear sfermion terms can be cast under matrix form:

\[
V_F \ni (U_R^i, U_R^i, D_R^i, D_R^i) \left( \begin{array}{cccc}
M_{U}^{2+} & M_{U}^{2+} & M_{D}^{2+} & M_{D}^{2+} \\
U_R^i & U_R^i & D_R^i & D_R^i \\
(N_L^i, E_i^L, E_i^R) \left( \begin{array}{c}
N_L^i \\
E_i^L \\
E_i^R \\
\end{array} \right)
\end{array} \right)
\]

with the matrix blocks:

\[
M_{U}^{2+} = \begin{pmatrix}
m_Q^2 + Y_u^2 |H_u^+|^2 + \frac{1}{4} \left( \frac{g^2}{8} - g^2 \right) \left( |H_u^+|^2 - |H_d^0|^2 \right) & Y_u \left[ A e^{-i \phi_{\alpha}} H_u^+ - \lambda e^{i \phi_{\alpha}} S H_d^0 \right] & m_Q^2 + Y_u^2 |H_u^+|^2 - \frac{g^2}{8} \left( |H_u^+|^2 - |H_d^0|^2 \right) \\
Y_u \left[ A e^{i \phi_{\alpha}} H_u^+ - \lambda e^{i \phi_{\alpha}} S H_d^0 \right]^* & m_Q^2 + Y_u^2 |H_u^+|^2 - \frac{g^2}{8} \left( |H_u^+|^2 - |H_d^0|^2 \right) \\
\end{pmatrix}
\]

\[
M_{D}^{2+} = \begin{pmatrix}
m_d^2 + Y_d^2 |H_d^0|^2 + \frac{1}{4} \left( \frac{g^2}{8} + g^2 \right) \left( |H_d^0|^2 - |H_u^+|^2 \right) & Y_d \left[ A e^{-i \phi_{\alpha}} H_d^0 - \lambda e^{i \phi_{\alpha}} S H_u^+ \right] & m_d^2 + Y_d^2 |H_d^0|^2 + \frac{g^2}{8} \left( |H_u^+|^2 - |H_d^0|^2 \right) \\
Y_d \left[ A e^{i \phi_{\alpha}} H_d^0 - \lambda e^{i \phi_{\alpha}} S H_u^+ \right]^* & m_d^2 + Y_d^2 |H_d^0|^2 + \frac{g^2}{8} \left( |H_u^+|^2 - |H_d^0|^2 \right) \\
\end{pmatrix}
\]

\[
M_{U}^{2+} = \begin{pmatrix}
- \frac{V^\dagger_{\text{CKM}} Y_u^2 H_d^0 H_u^0 - Y_d^2 V_{\text{CKM}}^* H_d^0 H_u^0 + \frac{2}{\sqrt{2}} V^\dagger_{\text{CKM}} (H_d^0 H_u^0 - H_u^0 H_d^0) & -V^\dagger_{\text{CKM}} Y_u \left[ A e^{-i \phi_{\alpha}} H_d^0 H_u^0 + \lambda e^{i \phi_{\alpha}} S H_u^0 \right] \\
- \frac{V^\dagger_{\text{CKM}} Y_d^2 H_u^0 H_u^0 - Y_d^2 V_{\text{CKM}}^* H_u^0 H_u^0 - \frac{2}{\sqrt{2}} V^\dagger_{\text{CKM}} (H_u^0 H_u^0 - H_u^0 H_d^0) & -V^\dagger_{\text{CKM}} Y_d \left[ A e^{-i \phi_{\alpha}} H_d^0 H_u^0 + \lambda e^{i \phi_{\alpha}} S H_d^0 \right] \\
\end{pmatrix}
\]

\[
M_N = m_N^2 - \frac{g^2 + g^2}{4} \left( (H_u^0|^2 - |H_d^0|^2) \right) + Y_u^2 H_d^0 H_u^0 + Y_d^2 H_u^0 H_d^0 + \left( \frac{g^2 + g^2}{4} \right) (H_u^0 H_u^0 - H_d^0 H_d^0)
\]

\[
M_E = \begin{pmatrix}
m_e^2 + Y_e^2 |H_u^0|^2 + \frac{g^2}{4} \left( |H_u^0|^2 - |H_d^0|^2 \right) & Y_e \left[ A e^{-i \phi_{\alpha}} H_u^0 H_u^0 - \lambda e^{i \phi_{\alpha}} S H_d^0 \right] & m_e^2 + Y_e^2 |H_u^0|^2 + \frac{g^2}{4} \left( |H_u^0|^2 - |H_d^0|^2 \right) \\
Y_e \left[ A e^{i \phi_{\alpha}} H_d^0 - \lambda e^{i \phi_{\alpha}} S H_u^0 \right]^* & m_e^2 + Y_e^2 |H_u^0|^2 + \frac{g^2}{4} \left( |H_u^0|^2 - |H_d^0|^2 \right) \\
\end{pmatrix}
\]

Moving to the v.e.v.’s, the matrices become block diagonal – each block being associated to a given electric charge of the sfermion fields. Under our Minimal Flavour Violation hypothesis the various generations also decouple so
that we are left with $2 \times 2$ (hermitian) mass-matrices $\langle M_F^2 \rangle$. Those can be diagonalized via unitary matrices $X_F$, according to:

$$\langle M_F^2 \rangle = X_F^\dagger \text{diag}(m_{\chi_1}^2, m_{\chi_2}^2) X_F$$

$$X_F = \begin{pmatrix} \cos \theta_F & -\sin \theta_F e^{i\varphi_F} \\ \sin \theta_F e^{-i\varphi_F} & \cos \theta_F \end{pmatrix}$$

$$m_{\chi_1}^2 = \frac{1}{2} \left[ \langle M_F^2 \rangle_{11} + \langle M_F^2 \rangle_{22} - \sqrt{\langle M_F^2 \rangle_{11}^2 - \langle M_F^2 \rangle_{22}^2 + 4 \langle M_F^2 \rangle_{12}^2} \right]$$

$$m_{\chi_2}^2 = \frac{1}{2} \left[ \langle M_F^2 \rangle_{11} + \langle M_F^2 \rangle_{22} + \sqrt{\langle M_F^2 \rangle_{11}^2 - \langle M_F^2 \rangle_{22}^2 + 4 \langle M_F^2 \rangle_{12}^2} \right]$$

$$\theta_F = \arctan \frac{\langle M_F^2 \rangle_{12} - \sqrt{\langle M_F^2 \rangle_{11}^2 - \langle M_F^2 \rangle_{22}^2 + 4 \langle M_F^2 \rangle_{12}^2}}{2 \langle M_F^2 \rangle_{12}}$$

The mass-states are given by $F_i = X_{iL}^F L + X_{iR}^F R^*$ (where, in our notation 1 $\leftrightarrow$ L and 2 $\leftrightarrow$ R).

### B.1.4 Charginos and neutralinos

The gaugino-higgsino-Higgs potential may also be cast under matrix form:

$$\mathcal{V}_\chi = \frac{1}{2} \chi^T \begin{pmatrix} 0 & M_{\chi^+} & M_{\chi^-} \\ M_{\chi^+} & 0 & M_{\chi^0} \\ M_{\chi^-} & M_{\chi^0} & 0 \end{pmatrix} \chi + \text{h.c.}$$

for $\chi = \begin{pmatrix} \chi^- \chi^0 \chi^+ \end{pmatrix}$.

$$\mathcal{M}_{\chi^-} = \begin{pmatrix} M_{e^0,M_2} e^{i\phi_{M_2}} & gH_u^0 e^{i\varphi_{H_u}} \\ 0 & 0 \end{pmatrix} = \mathcal{M}_{\chi^-}^T$$

$$\mathcal{M}_{\chi^0} = \begin{pmatrix} M_{e^0,M_2} e^{i\phi_{M_2}} & gH_u^0 e^{i\varphi_{H_u}} & 0 \\ 0 & 0 & -\lambda e^{i\varphi_S} H_d^0 \\ -\lambda e^{i\varphi_S} H_d^0 & 0 & 0 \end{pmatrix} = \mathcal{M}_{\chi^0}^T$$

### i) Charginos

The $2 \times 2$ chargino mass-matrix may be diagonalized via two unitary matrices $U$ and $V$:

$$\langle M_{\chi^\pm} \rangle = U^T \text{diag}(m_{\chi_1^\pm}, m_{\chi_2^\pm}) V.$$
which provide:

\[
\begin{align*}
\left\{ \begin{array}{l}
m_{\chi^+}^2 & = \frac{1}{2} \left[ \langle M_{\chi^+}^2 \rangle_{11} + \langle M_{\chi^+}^2 \rangle_{22} - \sqrt{\left( \langle M_{\chi^+}^2 \rangle_{11} - \langle M_{\chi^+}^2 \rangle_{22} \right)^2} + 4 \langle M_{\chi^+}^2 \rangle_{12}^2} \right] \\
m_{\chi^0}^2 & = \frac{1}{2} \left[ \langle M_{\chi^0}^2 \rangle_{11} + \langle M_{\chi^0}^2 \rangle_{22} + \sqrt{\left( \langle M_{\chi^0}^2 \rangle_{11} - \langle M_{\chi^0}^2 \rangle_{22} \right)^2} + 4 \langle M_{\chi^0}^2 \rangle_{12}^2} \right] \\
\end{array} \right. \\
\theta_V & = \arctan \frac{\langle M_{\chi^+}^2 \rangle_{12} - \langle M_{\chi^0}^2 \rangle_{12}}{\sqrt{2} \langle M_{\chi^0}^2 \rangle_{12}} \\
\varphi_V & = \arctan \frac{\langle M_{\chi^+}^2 \rangle_{12} + \langle M_{\chi^0}^2 \rangle_{12}}{\sqrt{2} \langle M_{\chi^0}^2 \rangle_{12}} \\
\end{align*}
\]

\[
U \equiv \begin{pmatrix}
e^{i\varphi_V} & 0 \\
0 & 1
\end{pmatrix} \begin{pmatrix}
\cos \theta_V & -\sin \theta_V e^{i\varphi_V} \\
\sin \theta_V e^{-i\varphi_V} & \cos \theta_V
\end{pmatrix} ; \\
V \equiv \begin{pmatrix}
1 & 0 \\
0 & e^{i\varphi_U}
\end{pmatrix} \begin{pmatrix}
\cos \theta_V & -\sin \theta_V e^{i\varphi_V} \\
\sin \theta_V e^{-i\varphi_V} & \cos \theta_V
\end{pmatrix}
\]

The choice of phases \( \varphi_U, \varphi_V \) is a priori arbitrary. We decide to determine them by the requirement that \( m_{\chi^\pm} \) and \( m_{\chi^0} \), obtained in the matrix product \( U^* \langle M_{\chi^+} \rangle V^* \), are real and positive. The associated mass-states are then:

\[
\chi^+ = V_{i1}(-i\tilde{w}^+) + V_{i2}\tilde{h}_u^+ \equiv V_{iu}(-i\tilde{w}^+) + V_{iu}\tilde{h}_u^+ \\
\chi^0 = U_{i1}(-i\tilde{w}^-) + U_{i2}\tilde{h}_d^- \equiv U_{iw}(-i\tilde{w}^-) + U_{id}\tilde{h}_d^-
\]

ii) Neutralinos

The 5 \times 5 neutralino mass-matrix is symmetric, hence is diagonalizable via a single unitary matrix \( N \):

\[
\langle M_{\chi^0} \rangle = N^T \text{diag}(m_{\chi^0}^2, i = 1, \ldots, 5) N
\]

As before, we first consider the hermitian matrix

\[
\langle M_{\chi^0}^2 \rangle \equiv \langle M_{\chi^0} \rangle^T \langle M_{\chi^0} \rangle = N^T \text{diag}(m_{\chi^0}^2, i = 1, \ldots, 5) N
\]

This hermitian matrix – or equivalently the 10 \times 10 symmetric matrix

\[
\begin{pmatrix}
\text{Re} & \text{Im} \\
-\text{Im} & \text{Re}
\end{pmatrix} \langle M_{\chi^0} \rangle
\]

– may be diagonalized numerically, providing us with \( m_{\chi^0}^2, i = 1, \ldots, 5 \) and a diagonalization matrix \( N_0 \). We define \( N = \text{diag}(e^{i\varphi_{\chi^0}}, i = 1, \ldots, 5) N_0 \), where the phases \( \varphi_{\chi^0}, i = 1, \ldots, 5 \) are determined by the requirement that the masses \( m_{\chi^0}^2, i = 1, \ldots, 5 \) obtained from the matrix product \( N^* \langle M_{\chi^0} \rangle N^T \) are real and positive. The neutralino mass-states are then defined as:

\[
\chi^0 = N_{i1}(-i\tilde{b}) + N_{i2}(-i\tilde{w}^3) + N_{i3}\tilde{h}_u^0 + N_{i4}\tilde{h}_d^0 + N_{i5}\tilde{h}_s^0 \equiv N_{ib}(-i\tilde{b}) + N_{iw}(-i\tilde{w}^3) + N_{iu}\tilde{h}_u^0 + N_{id}\tilde{h}_d^0 + N_{is}\tilde{h}_s^0
\]

B.1.5 Gluinos

The gluons of course remain massless. Concerning their supersymmetric partners, the gluino bilinear terms read:

\[
V_g = -M_3 e^{i\phi_{M_3}} \tilde{g}_a \tilde{g}_a + h.c.
\]

so that we define the mass states \( \tilde{g}_a \equiv -e^{i\phi_{M_3}} \tilde{g}_a \), with mass \( M_3 \).

B.1.6 Higgs sector

The tree-level Higgs potential is given in Eq \[3\]

i) Minimization Conditions
First derivatives of the potential must vanish at the minimum, which provides:

\[
\begin{align*}
\frac{1}{2} \left\langle \frac{\partial V_H^0}{\partial h^0_u/\sqrt{2}} \right\rangle &= 0 = \left[ m^2_{H_u} + \lambda^2 (s^2 + v_d^2) + g^2 + g^2 \right] v_u - \lambda s \left[ A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_n) \right] v_d \\
\frac{1}{2} \left\langle \frac{\partial V_H^0}{\partial h^0_d/\sqrt{2}} \right\rangle &= 0 = \left[ m^2_{H_d} + \lambda^2 (s^2 + v_u^2) + g^2 + g^2 \right] v_d - \lambda s \left[ A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_n) \right] v_u \\
\frac{1}{2} \left\langle \frac{\partial V_H^0}{\partial h^0_u/\sqrt{2}} \right\rangle &= 0 = \left[ m_2^2 + \kappa s (A_\lambda \cos \varphi_2) + 2 \kappa s + \lambda^2 (v_u^2 + v_d^2) \right] s - \lambda \left[ A_\lambda \cos \varphi_1 + 2 \kappa s \cos(\varphi_\lambda - \varphi_n) \right] v_u v_d \\
\frac{1}{2} \left\langle \frac{\partial V_H^0}{\partial h^0_d/\sqrt{2}} \right\rangle &= 0 = \lambda s \left[ A_\lambda \sin \varphi_1 + \kappa s \sin(\varphi_\lambda - \varphi_n) \right] v_d \\
\frac{1}{2} \left\langle \frac{\partial V_H^0}{\partial h^0_u/\sqrt{2}} \right\rangle &= 0 = \lambda s \left[ A_\lambda \sin \varphi_1 + \kappa s \sin(\varphi_\lambda - \varphi_n) \right] v_u \\
\frac{1}{2} \left\langle \frac{\partial V_H^0}{\partial h^0_d/\sqrt{2}} \right\rangle &= 0 = \lambda \left[ A_\lambda \sin \varphi_1 - 2 \kappa s \sin(\varphi_\lambda - \varphi_n) \right] v_u v_d - \kappa s^2 A_\kappa \sin \varphi_2 \\
\end{align*}
\]

So that one can express certain parameters in terms of the v.e.v.'s:

\[
\begin{align*}
& m^2_{H_u} = \lambda s \left[ A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_n) \right] \frac{v_d}{v_u} - \lambda^2 (s^2 + v_d^2) - \frac{g^2 + g^2}{4} \left( v_u - v_d \right) \\
& m^2_{H_d} = \lambda s \left[ A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_n) \right] \frac{v_u}{v_d} - \lambda^2 (s^2 + v_u^2) + \frac{g^2 + g^2}{4} \left( v_u - v_d \right) \\
& m_2^2 = \lambda \left[ A_\lambda \cos \varphi_1 + 2 \kappa s \cos(\varphi_\lambda - \varphi_n) \right] \frac{v_u v_d}{s} - \kappa s (A_\lambda \cos \varphi_2) + 2 \kappa s - \lambda^2 (v_u^2 + v_d^2) \\
& A_\lambda \sin \varphi_1 = -\kappa s \sin(\varphi_\lambda - \varphi_n) \\
& A_\kappa \sin \varphi_2 = \frac{\lambda}{\kappa} [A_\lambda \sin \varphi_1 - 2 \kappa s \sin(\varphi_\lambda - \varphi_n)] \frac{v_u v_d}{s^2} = -3 \lambda v_u v_d \sin(\varphi_\lambda - \varphi_n) \\
\end{align*}
\]

\[\text{ii) Charged Higgs}\]

The 2 × 2 charged-Higgs bilinear terms read:

\[
V_{H^\pm} = \left( H_u^-, H_d^- \right) \mathcal{M}^2_{H^\pm} \left( \begin{array}{c} H_u^+ \\ H_d^+ \end{array} \right) 
\]

\[
\mathcal{M}^2_{H^\pm}|_{11} = m^2_{H_u} + \lambda^2 |S|^2 + \frac{g^2 + g^2}{4} \left( |H_u^0|^2 - |H_d^0|^2 \right) + \frac{g^2}{2} |H_d^0|^2 + \lambda^2 H_u^+ H_d^- + \frac{g^2 + g^2}{4} H_u^0 H_u^- \\
= \lambda s \left[ A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_n) \right] \frac{v_d}{v_u} - \left( \lambda^2 - \frac{g^2}{2} \right) v_u \\
+ \lambda^2 (|S|^2 - s^2) + \frac{g^2 + g^2}{4} \left( |H_u^0|^2 - |H_d^0|^2 - v_u^2 + v_d^2 \right) + \frac{g^2}{2} (|H_d^0|^2 - v_u^2) + \lambda^2 H_u^+ H_d^- + \frac{g^2 + g^2}{4} H_u^0 H_u^- \\
\]

\[
\mathcal{M}^2_{H^\pm}|_{22} = m^2_{H_d} + \lambda^2 |S|^2 = -\frac{g^2 + g^2}{4} \left( |H_u^0|^2 - |H_d^0|^2 \right) + \frac{g^2}{2} |H_u^0|^2 + \lambda^2 H_u^+ H_d^- + \frac{g^2 + g^2}{4} H_u^0 H_u^- \\
= \lambda s \left[ A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_n) \right] \frac{v_u}{v_d} - \left( \lambda^2 - \frac{g^2}{2} \right) v_d \\
+ \lambda^2 (|S|^2 - s^2) - \frac{g^2 + g^2}{4} \left( |H_u^0|^2 - |H_d^0|^2 - v_u^2 + v_d^2 \right) + \frac{g^2}{2} (|H_u^0|^2 - v_u^2) + \lambda^2 H_u^+ H_u^- + \frac{g^2 + g^2}{4} H_u^0 H_u^- \\
\]

\[
\mathcal{M}^2_{H^\pm}|_{12} = \lambda \left[ A_\lambda e^{-i \varphi_1} S^* + \kappa e^{-i (\varphi_\lambda - \varphi_n)} S^* \right] - \left( \lambda^2 - \frac{g^2}{2} \right) H_u^0 H_d^0 + \left( \lambda^2 - \frac{g^2 + g^2}{4} \right) H_u^+ H_d^- = \mathcal{M}^2_{H^\pm}|^*_{12} \\
= \lambda s \left[ A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_n) \right] - \left( \lambda^2 - \frac{g^2}{2} \right) v_u v_d + \left( \lambda^2 - \frac{g^2 + g^2}{4} \right) H_u^+ H_d^- \\
+ \lambda \left[ A_\lambda \cos \varphi_1 (S^* - s) + \kappa \cos(\varphi_\lambda - \varphi_n)(S^2 - s^2) - i \kappa \sin(\varphi_\lambda - \varphi_n)(S^2 - S^2) \right] - \left( \lambda^2 - \frac{g^2}{2} \right) (H_u^0 H_d^0 - v_u v_d) \\
\]
Obviously,
\[
\langle \mathcal{M}_{H^\pm}^2 \rangle = \left\{ \lambda s [A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_\kappa)] - \left( \lambda^2 - \frac{g^2}{2} \right) v_u v_d \right\} \left( \begin{array}{c} v_d \\ v_u \end{array} \right) \left( \begin{array}{c} 1 \\ 1 \end{array} \right) \\
= \left( \begin{array}{c} -\sin \beta & \cos \beta \\ \cos \beta & \sin \beta \end{array} \right) \left( \begin{array}{c} 0 \\ 0 \end{array} \right) \left( \begin{array}{c} -\sin \beta & \cos \beta \\ \cos \beta & \sin \beta \end{array} \right) m_{H^\pm}^2 \equiv \left\{ \lambda s [A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_\kappa)] - \left( \lambda^2 - \frac{g^2}{2} \right) \right\} (v_u^2 + v_d^2) ; \quad \tan \beta \equiv \frac{v_u}{v_d} (59)
\]
with the Goldstone boson \(G^\pm = -\sin \beta H_d^\pm + \cos \beta H_u^\pm\) and the charged Higgs state \(H^\pm = \cos \beta H_u^\pm + \sin \beta H_d^\pm\).

We will denote the corresponding rotation matrix as follows:
\[
X^C \equiv \left( \begin{array}{c} -\sin \beta & \cos \beta \\ \cos \beta & \sin \beta \end{array} \right) ; \quad H_1^\pm \equiv G^\pm ; \quad H_2^\pm \equiv H^\pm
\]

### iii) Neutral Higgs

The symmetric 6 \times 6 bilinear Higgs matrix \(\mathcal{M}_{H^0}^2 \equiv \left[ \frac{g^2}{2 \cos \varphi_1} S_{ij}, S_{ij} = h_u^0, h_d^0, \alpha_v^0, \alpha_u^0, \alpha_d^0, \alpha_u^0 \right]\) includes the following elements:
\[
\mathcal{M}_{H^0}^2 |_{11} = m_{H_u}^2 + \lambda^2 |(S|^2 + |H_u^0|^2)| + \frac{g^2 + g^2}{4} \left( 2 \Re(H_u^0) \Re(H_d^0) \right) \left( \lambda^2 - \frac{g^2 + g^2}{4} \right) \Re(H_u^0) \Re(H_d^0) \\
= -\lambda s [A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_\kappa)] v_u v_d - \left( \lambda^2 - \frac{g^2 + g^2}{4} \right) \Re(H_u^0) \Re(H_d^0) \\
+ \lambda^2 |(S|^2 + |H_u^0|^2)| + \frac{g^2 + g^2}{4} \left( 2 \Re(H_u^0) \Re(H_d^0) \right) \left( \lambda^2 - \frac{g^2 + g^2}{4} \right) \Re(H_u^0) \Re(H_d^0) \\
\mathcal{M}_{H^0}^2 |_{22} = m_{H_d}^2 + \lambda^2 |(S|^2 + |H_u^0|^2)| + \frac{g^2 + g^2}{4} \left( 2 \Re(H_d^0) \Re(H_u^0) \right) \left( \lambda^2 - \frac{g^2 + g^2}{4} \right) \Re(H_u^0) \Re(H_d^0) \\
= -\lambda s [A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_\kappa)] v_u v_d - \left( \lambda^2 - \frac{g^2 + g^2}{4} \right) \Re(H_u^0) \Re(H_d^0) \\
+ \lambda^2 |(S|^2 + |H_u^0|^2)| + \frac{g^2 + g^2}{4} \left( 2 \Re(H_d^0) \Re(H_u^0) \right) \left( \lambda^2 - \frac{g^2 + g^2}{4} \right) \Re(H_u^0) \Re(H_d^0) \\
\mathcal{M}_{H^0}^2 |_{13} = -\lambda v_d [A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_\kappa)] + 2 \lambda^2 \Re(S) \Re(H_u^0) \\
= -\lambda v_d [A_\lambda \cos \varphi_1 + \kappa s \cos(\varphi_\lambda - \varphi_\kappa) + 2 \lambda^2 s v_u \\
- \lambda [A_\lambda \cos \varphi_1 \Re(H_d^0) - v_d] + 2 \kappa \cos(\varphi_\lambda - \varphi_\kappa) \Re(S^* H_u^0 - S v_d) \\

\]

As for the case of the charged Higgs, the Goldstone boson \( G^0 \equiv -\sin \beta a_0^+ + \cos \beta a_0^0 \) can be separated from the doublet CP-odd state \( a_0^2 \equiv \cos \beta a_0^+ + \sin \beta a_0^0 \) by a rotation of angle \( \beta \). The remaining (symmetric) 5 \times 5 sub-matrix of massive states \( \tilde{\mathcal{M}}_{H^0} \) may be diagonalized (numerically) through an orthogonal matrix \( X^{H^0} \):

\[
\tilde{\mathcal{M}}_{H^0}^2 = X^{H^0 T} \text{diag}(m_{S_i}^2, i = 1, \ldots, 5) X^{H^0}
\]
The corresponding mass-states are then:

\[ S_i^0 = X_{i1}^0 u_{i1}^0 + X_{i2}^0 h_{i2}^0 + X_{i3}^0 h_{i3}^0 + X_{i4}^0 a_1^0 + X_{i5}^0 a_2^0 = X_{i1}^R h_{i1}^0 + X_{i2}^R h_{i2}^0 + X_{i3}^R h_{i3}^0 + X_{i4}^L a_1^0 + X_{i5}^L a_2^0 \]

iv) Charged-Neutral Higgs terms

For completeness we indicate the bilinear terms mixing charged and neutral Higgs states (note that \( M^2_{\bar{s}^i s^0} = \mathcal{M}^2 |_{\bar{s}^i s^0} \)):

\[
\begin{align*}
\mathcal{M}^2_{H^+ h_u^0} &= \frac{1}{\sqrt{2}} \left[ -(\lambda^2 - \frac{g^2}{2}) H_d^0 H_u^0 + \frac{g'^2 + g^2}{2} H_u^0 \text{Re}(H_u^0) \right] \\
\mathcal{M}^2_{H^+ h_d^0} &= \frac{1}{\sqrt{2}} \left[ -(\lambda^2 - \frac{g^2}{2}) H_d^0 H_u^0 - \frac{g^2 - g^2}{2} H_d^0 \text{Re}(H_u^0) \right] \\
\mathcal{M}^2_{H^+ h_u^0} &= \frac{1}{\sqrt{2}} \left[ \lambda \left( A_\lambda \bar{e}^\dagger \phi_1 + 2 \kappa_\lambda (\phi_\lambda - \phi_\lambda^*) S_u^+ \right) H_d^- + 2 \lambda^2 \text{Re}(S) H_u^- \right] \\
\mathcal{M}^2_{H^+ h_d^0} &= \frac{1}{\sqrt{2}} \left[ \lambda \left( A_\lambda \bar{e}^\dagger \phi_1 - 2 \kappa_\lambda (\phi_\lambda - \phi_\lambda^*) S_u^- \right) H_d^- + 2 \lambda^2 \text{Im}(S) H_d^- \right] \\
\mathcal{M}^2_{H^+ h_u^0} &= \frac{1}{\sqrt{2}} \left[ -(\lambda^2 - \frac{g^2}{2}) H_d^- H_u^- + \frac{g'^2 + g^2}{2} H_u^- \text{Im}(H_u^0) \right] \\
\mathcal{M}^2_{H^+ h_d^0} &= \frac{1}{\sqrt{2}} \left[ -(\lambda^2 - \frac{g^2}{2}) H_d^- H_u^- - \frac{g^2 - g^2}{2} H_u^- \text{Im}(H_u^0) \right] \\
\mathcal{M}^2_{H^+ h_u^0} &= \frac{1}{\sqrt{2}} \left[ \lambda \left( A_\lambda \bar{e}^\dagger \phi_1 - 2 \kappa_\lambda (\phi_\lambda - \phi_\lambda^*) S_u^- \right) H_d^- + 2 \lambda^2 \text{Im}(S) H_d^- \right] \\
\mathcal{M}^2_{H^+ h_d^0} &= \frac{1}{\sqrt{2}} \left[ \lambda \left( A_\lambda \bar{e}^\dagger \phi_1 + 2 \kappa_\lambda (\phi_\lambda - \phi_\lambda^*) S_u^+ \right) H_d^- + 2 \lambda^2 \text{Re}(S) H_d^- \right]
\end{align*}
\]

B.2 Tree-level Higgs couplings

Having presented the spectrum and our conventions, we may now turn to the Higgs couplings.

B.2.1 Higgs-SM fermions

Employing the Dirac-fermion notation, the Higgs couplings to SM fermions may be cast in the following form (with the usual left- and right-handed projectors \( P_{L,R} \)):

\[ \mathcal{V}_f \ni \bar{f} \left[ g_{L}^{S f f} P_L + g_{R}^{S f f} P_R \right] f^c S \quad ; \quad g_{L}^{S f f} = (g_{L}^{S f f})^* \]  

(61)

with the (non-vanishing) values of \( g_{L}^{S f f} \):

\[
\begin{align*}
g_{L}^{S_{u} u} &= \frac{Y_u}{\sqrt{2}} \left[ X^R_{i1} + i X^I_{i1} \right] \quad & g_{L}^{H^+ u} &= -Y_u \cos \beta \\
g_{L}^{S_{d} d} &= \frac{Y_d}{\sqrt{2}} \left[ X^R_{i2} + i X^I_{i2} \right] \quad & g_{L}^{H^+ d} &= -Y_d \sin \beta \\
g_{L}^{S_{e} e} &= \frac{Y_e}{\sqrt{2}} \left[ X^R_{i3} + i X^I_{i3} \right] \quad & g_{L}^{H^+ e} &= -Y_e \sin \beta 
\end{align*}
\]
B.2.2 Higgs-gauge

The situation is unchanged with respect to the CP-conserving case:

\[ \mathcal{V}_G \ni g_{\mu}^{SV} V^{\mu} V^{\nu} + g_{\mu}^{S} V^{\mu} V^{\nu} + g (\partial_{\mu} \delta - S \partial_{\mu} S) V^{\mu} \]  

(62)

\[ 2g_{\mu\nu}^{S_Z} = g_{\mu\nu} \frac{g^2 + g^2}{\sqrt{2}} (v_d X_{id}^R + v_u X_{iu}^R) \]

\[ g_{\mu\nu}^{S_W W^-} = g_{\mu\nu} \frac{g^2}{\sqrt{2}} (v_d X_{id}^R + v_u X_{iu}^R) \]

\[ g_{\mu\nu}^{H^+ H^- \gamma} = g_{\mu\nu} \frac{g^2}{\sqrt{2} (g^2 + g^2)} \delta_{ij} \]

\[ g_{\mu\nu}^{H^+ H^- Z} = g_{\mu\nu} \frac{g^2 - g^2}{2 \sqrt{2} (g^2 + g^2)} \delta_{ij} \]

\[ g_{\mu\nu}^{H^+ H^- ZZ} = g_{\mu\nu} \frac{(g^2 - g^2)^2}{2 (g^2 + g^2)} \delta_{ij} \]

\[ g_{\mu\nu}^{H^+ H^- W^-} = g_{\mu\nu} \frac{g^2 + g^2}{2 (g^2 + g^2)} \]

\[ g_{\mu\nu}^{S_S Z} = \frac{1}{2} \left[ \mathcal{V}^2 v_u X_{iu}^R + \frac{1}{4} \left( \frac{g^2}{3} - g^2 \right) (v_u X_{iu}^R - v_d X_{id}^R) \right] X_{kl}^U (X_{ikl}^U)^* \]

\[ + \frac{1}{2} \left[ \mathcal{V}^2 v_u X_{iu}^R - \frac{g^2}{3} (v_u X_{iu}^R - v_d X_{id}^R) \right] X_{klR}^U (X_{iklR}^U)^* \]

\[ + \frac{Y_u}{\sqrt{2}} \left[ A_u e^{i \varphi_u} (X_{R}^{X_{iu}} + i X_{L}^{X_{iu}}) - \lambda e^{i \varphi_u} (s (X_{R}^{X_{iu}} - i X_{L}^{X_{iu}}) + v_d (X_{R}^{X_{iu}} - i X_{L}^{X_{iu}})) \right] X_{klR}^U (X_{iklR}^U)^* \]

\[ + \frac{Y_u}{\sqrt{2}} \left[ A_u e^{-i \varphi_u} (X_{R}^{X_{iu}} - i X_{L}^{X_{iu}}) - \lambda e^{-i \varphi_u} (s (X_{R}^{X_{iu}} + i X_{L}^{X_{iu}}) + v_d (X_{R}^{X_{iu}} + i X_{L}^{X_{iu}})) \right] X_{klL}^U (X_{iklL}^U)^* \]

\[ g_{\mu\nu}^{S_S D_i D_i} = \frac{1}{2} \left[ \mathcal{V}^2 v_d X_{id}^R + \frac{1}{4} \left( \frac{g^2}{3} + g^2 \right) (v_u X_{iu}^R - v_d X_{id}^R) \right] X_{kl}^D (X_{ikl}^D)^* \]

\[ + \frac{1}{2} \left[ \mathcal{V}^2 v_d X_{id}^R - \frac{g^2}{3} (v_u X_{iu}^R - v_d X_{id}^R) \right] X_{klR}^D (X_{iklR}^D)^* \]

\[ + \frac{Y_d}{\sqrt{2}} \left[ A_d e^{i \varphi_d} (X_{R}^{X_{id}} + i X_{L}^{X_{id}}) - \lambda e^{i \varphi_d} (s (X_{R}^{X_{id}} - i X_{L}^{X_{id}}) + v_d (X_{R}^{X_{id}} - i X_{L}^{X_{id}})) \right] X_{klR}^D (X_{iklR}^D)^* \]

\[ + \frac{Y_d}{\sqrt{2}} \left[ A_d e^{-i \varphi_d} (X_{R}^{X_{id}} - i X_{L}^{X_{id}}) - \lambda e^{-i \varphi_d} (s (X_{R}^{X_{id}} + i X_{L}^{X_{id}}) + v_d (X_{R}^{X_{id}} + i X_{L}^{X_{id}})) \right] X_{klL}^D (X_{iklL}^D)^* \]

B.2.4 Higgs-charginos/neutrinos

As for the Higgs-fermion couplings:

\[g^{S_H^+X_L^*k_{i1}^+} = \left[ \frac{\sqrt{2}}{2} \left\{ [g(X^R_{id} - iX^I_{id}) U_{id}^* V_{id} + g(X^R_{id} - iX^I_{id}) U_{id}^* V_{id} + \lambda e^{i\varphi_c} (X^R_{id} + iX^I_{id}) U_{id}^* V_{id}] \right\} \right] \]

\[g^{S_H^+X_L^*k_{i1}^0} = \frac{1}{\sqrt{2}} \left\{ \left[ (X^R_{id} - iX^I_{id}) (N^*_{ku} N^*_{id} + N^*_{ku} N^*_{id}) - (X^R_{id} - iX^I_{id}) (N^*_{ku} N^*_{id} + N^*_{ku} N^*_{id}) \right] \right\} \]

\[g^{S_H^+X_L^*k_{i1}^0} = \frac{1}{\sqrt{2}} \left\{ \left[ (X^R_{id} - iX^I_{id}) (N^*_{ku} N^*_{id} + N^*_{ku} N^*_{id}) - (X^R_{id} - iX^I_{id}) (N^*_{ku} N^*_{id} + N^*_{ku} N^*_{id}) \right] \right\} \]

\[g^{H^+_ij^*X_L^*k_{i1}^0} = \frac{1}{\sqrt{2}} \left\{ (X^R_{id} - iX^I_{id}) (N^*_{ku} N^*_{id} + N^*_{ku} N^*_{id}) - (X^R_{id} - iX^I_{id}) (N^*_{ku} N^*_{id} + N^*_{ku} N^*_{id}) \right\} \]

\[g^{H^+_ij^*X_L^*k_{i1}^0} = \frac{1}{\sqrt{2}} \left\{ (X^R_{id} - iX^I_{id}) (N^*_{ku} N^*_{id} + N^*_{ku} N^*_{id}) - (X^R_{id} - iX^I_{id}) (N^*_{ku} N^*_{id} + N^*_{ku} N^*_{id}) \right\} \]

\[g^{H^+_ij^*X_L^*k_{i1}^0} = \frac{1}{\sqrt{2}} \left\{ (X^R_{id} - iX^I_{id}) (N^*_{ku} N^*_{id} + N^*_{ku} N^*_{id}) - (X^R_{id} - iX^I_{id}) (N^*_{ku} N^*_{id} + N^*_{ku} N^*_{id}) \right\} \]
B.2.5 Higgs-to-Higgs couplings

From the tree-level potential of Eq.10 one may derive the trilinear and quartic Higgs couplings:

\[ g_{ij}^{S(i)}g_{ik}^{S(k)} = \frac{1}{2} \left\{ g_{ij}^{2} + g_{ij}^{2} - \frac{g_{ij}^{2} + g_{ij}^{2}}{4} \left[ \nu_{u} \left( \Pi_{ij}^{S(uuu)} - \Pi_{ij}^{S(ddd)} + \Pi_{ij}^{S(ddd)} - \Pi_{ij}^{S(uuu)} \right) + v_{d} \left( \Pi_{ij}^{S(ddd)} + \Pi_{ij}^{S(uuu)} - \Pi_{ij}^{S(ddd)} + \Pi_{ij}^{S(uuu)} \right) \right] \right\} \]

\[ + \lambda^{2} \left[ \Phi_{ij}^{S(uuu)} + \Phi_{ij}^{S(ddd)} + \Phi_{ij}^{S(ddd)} + \Phi_{ij}^{S(uuu)} \right] + v_{u} \left( \Pi_{ij}^{S(ddd)} + \Pi_{ij}^{S(uuu)} + \Pi_{ij}^{S(ddd)} + \Pi_{ij}^{S(uuu)} \right) \]

\[- \lambda_{\alpha} \cos(\varphi_{\lambda} - \varphi_{\alpha}) \left[ 2s \left( \Pi_{ij}^{S(uds)} + \Pi_{ij}^{S(uds)} + \Pi_{ij}^{S(uds)} + \Pi_{ij}^{S(uds)} \right) + v_{d} \left( \Pi_{ij}^{S(uds)} - \Pi_{ij}^{S(uds)} + \Pi_{ij}^{S(uds)} - \Pi_{ij}^{S(uds)} \right) \right] \]

\[ + v_{u} \left( \Pi_{ij}^{S(dss)} - \Pi_{ij}^{S(dss)} + 2\Pi_{ij}^{S(dss)} \right) + \frac{7}{3} \lambda_{\alpha} \cos(\varphi_{\lambda} - \varphi_{\alpha}) \left[ \Pi_{ij}^{S(sss)} - 3\Pi_{ij}^{S(sss)} + 2\Pi_{ij}^{S(sss)} \right] + 2\lambda^{2} \left[ \Pi_{ij}^{S(sss)} + \Pi_{ij}^{S(sss)} \right] \]

where:

\[ (\Pi)_{ij}^{a,b,c}(x) = \frac{1}{2} \left[ \lambda_{a,b,c} x^{R_{i} R_{j} R_{k} R_{l}} + x^{R_{i} R_{j} R_{k} R_{l}} + x^{R_{i} R_{j} R_{k} R_{l}} + x^{R_{i} R_{j} R_{k} R_{l}} \right] \]

\[ (\Pi)_{ij}^{a,b,c}(x) = \frac{1}{2} \left[ \lambda_{a,b,c} x^{R_{i} R_{j} R_{k} R_{l}} + x^{R_{i} R_{j} R_{k} R_{l}} + x^{R_{i} R_{j} R_{k} R_{l}} + x^{R_{i} R_{j} R_{k} R_{l}} \right] \]

\[ (\Pi)_{ij}^{a,b,c}(x) = \frac{1}{2} \left[ \lambda_{a,b,c} x^{R_{i} R_{j} R_{k} R_{l}} + x^{R_{i} R_{j} R_{k} R_{l}} + x^{R_{i} R_{j} R_{k} R_{l}} + x^{R_{i} R_{j} R_{k} R_{l}} \right] \]

\[ (\Pi)_{ij}^{a,b,c}(x) = \frac{1}{2} \left[ \lambda_{a,b,c} x^{R_{i} R_{j} R_{k} R_{l}} + x^{R_{i} R_{j} R_{k} R_{l}} + x^{R_{i} R_{j} R_{k} R_{l}} + x^{R_{i} R_{j} R_{k} R_{l}} \right] \]
where:

\[ \Pi_{ijkl}^{ab} = \sum_{\sigma \in S_4} X_{\sigma(i)a}^{R} X_{\sigma(j)b}^{R} X_{\sigma(k)c}^{R} X_{\sigma(l)d}^{R} \]

\[ \Pi_{ijkl}^{abP} = \sum_{\sigma \in S_4} X_{\sigma(i)a}^{R} X_{\sigma(j)b}^{I} X_{\sigma(k)c}^{R} X_{\sigma(l)d}^{I} \]

\[ \Pi_{ijkl}^{abP} = \sum_{\sigma \in S_4} X_{\sigma(i)a}^{R} X_{\sigma(j)b}^{R} X_{\sigma(k)c}^{I} X_{\sigma(l)d}^{I} \]

\[ g_{\eta_i}^{R} H_{\eta_i}^{R} = \frac{g^2}{4} \left[ X_{\eta_i}^{R} X_{\eta_i}^{R} - X_{\eta_i}^{I} X_{\eta_i}^{I} \right] \left( X_{\eta_i}^{C} X_{\eta_i}^{C} - X_{\eta_i}^{C} X_{\eta_i}^{C} \right) \]

\[ + \frac{g^2}{4} \left[ X_{\eta_i}^{R} X_{\eta_i}^{R} + X_{\eta_i}^{I} X_{\eta_i}^{I} + X_{\eta_i}^{R} X_{\eta_i}^{R} + X_{\eta_i}^{I} X_{\eta_i}^{I} \right] \left( X_{\eta_i}^{C} X_{\eta_i}^{C} + X_{\eta_i}^{C} X_{\eta_i}^{C} \right) \]

\[ + \frac{\lambda}{2} \left( X_{\eta_i}^{C} X_{\eta_i}^{C} - X_{\eta_i}^{C} X_{\eta_i}^{C} \right) \left( X_{\eta_i}^{C} X_{\eta_i}^{C} + X_{\eta_i}^{C} X_{\eta_i}^{C} \right) \]

\[ + \lambda \kappa \left[ \cos(\varphi_\eta - \varphi_\kappa) \left( X_{\eta_i}^{R} X_{\eta_i}^{R} - X_{\eta_i}^{I} X_{\eta_i}^{I} \right) + \sin(\varphi_\eta - \varphi_\kappa) \left( X_{\eta_i}^{R} X_{\eta_i}^{R} + X_{\eta_i}^{R} X_{\eta_i}^{R} \right) \right] \]

\[ + \lambda \kappa \left[ \cos(\varphi_\eta - \varphi_\kappa) \left( X_{\eta_i}^{R} X_{\eta_i}^{R} - X_{\eta_i}^{I} X_{\eta_i}^{I} \right) - \cos(\varphi_\eta - \varphi_\kappa) \left( X_{\eta_i}^{R} X_{\eta_i}^{R} + X_{\eta_i}^{R} X_{\eta_i}^{R} \right) \right] \]

\[ + \lambda \kappa \left[ \cos(\varphi_\eta - \varphi_\kappa) \left( X_{\eta_i}^{R} X_{\eta_i}^{R} - X_{\eta_i}^{I} X_{\eta_i}^{I} \right) - \cos(\varphi_\eta - \varphi_\kappa) \left( X_{\eta_i}^{R} X_{\eta_i}^{R} + X_{\eta_i}^{R} X_{\eta_i}^{R} \right) \right] \]

\[ B.3 \quad Other \ couplings \]

**B.3.1 Chargino - Sfermion - SM fermion**

For each fermion / sfermion generation (with the convention of Eq.\ref{eq:61}):

\[ \tilde{U}_L^{\gamma} = Y_d U_{L}^{\gamma} \]

\[ \tilde{V}_L^{\gamma} = g_{R} U_{L}^{\gamma} \]

\[ \tilde{D}_L^{\gamma} = Y_d D_{L}^{\gamma} \]

\[ \tilde{E}_L^{\gamma} = Y_d E_{L}^{\gamma} \]

\[ \tilde{N}_L^{\gamma} = Y_d N_{L}^{\gamma} \]

\[ \tilde{E}_L^{\gamma} = \bar{Y}_d E_{L}^{\gamma} \]

\[ \tilde{D}_L^{\gamma} = \bar{Y}_d D_{L}^{\gamma} \]

\[ \tilde{V}_L^{\gamma} = \bar{Y}_d V_{L}^{\gamma} \]

\[ \tilde{N}_L^{\gamma} = \bar{Y}_d N_{L}^{\gamma} \]

**B.3.2 Neutralino - Sfermion - SM fermion**

For each fermion / sfermion generation:

\[ \tilde{U}_L^{\gamma} = -Y_u U_{L}^{\gamma} - \frac{1}{\sqrt{2}} \left( \frac{g}{3} N_{L}^{\gamma} + g N_{L}^{\gamma} \right) X_{L}^{\gamma} \]

\[ \tilde{V}_L^{\gamma} = -Y_u V_{L}^{\gamma} - \frac{1}{\sqrt{2}} \left( \frac{g}{3} N_{L}^{\gamma} + g N_{L}^{\gamma} \right) X_{L}^{\gamma} \]

\[ \tilde{D}_L^{\gamma} = -Y_d D_{L}^{\gamma} - \frac{1}{\sqrt{2}} \left( \frac{g}{3} N_{L}^{\gamma} + g N_{L}^{\gamma} \right) X_{L}^{\gamma} \]

\[ \tilde{E}_L^{\gamma} = -Y_e E_{L}^{\gamma} - \frac{1}{\sqrt{2}} \left( \frac{g}{3} N_{L}^{\gamma} + g N_{L}^{\gamma} \right) X_{L}^{\gamma} \]

**B.3.3 Chargino and Neutralino gauge couplings**

Using the notation:

\[ \mathcal{V}_f \equiv V_{\bar{f}} \gamma^\mu \left[ g_{L}^{Vf} P_L + g_{R}^{Vf} P_R \right] f' \]

\[ \mathcal{V}_f \equiv V_{\bar{f}} \gamma^\mu \left[ g_{L}^{Vf} P_L + g_{R}^{Vf} P_R \right] f' \]

\[ g_{L}^{Vf} = \left( g_{L}^{Vf} \right)^* \quad g_{R}^{Vf} = \left( g_{R}^{Vf} \right)^* \quad \text{(64)} \]
the chargino and neutralino gauge couplings may be written:

\[
\begin{align*}
\gamma \chi^0 \chi^0 &= g_{g_L} \frac{g' L}{\sqrt{g^2 + g'^2}} \\
\gamma \chi^+ \chi^0 &= g_{g_L} \frac{g' L}{\sqrt{g^2 + g'^2}} \left( V_{iw} V_{jw}^* + \frac{1}{2} V_{iu} V_{jw}^* - s_w^2 \delta_{ij} \right) \\
Z \chi^0 \chi^0 &= g_{g_L} \frac{g' L}{\sqrt{g^2 + g'^2}} \left( N_{id} N_{id}^* - N_{iu} N_{iw}^* \right) \\
W^- \chi^0 \chi^0 &= g \left( \frac{1}{\sqrt{2}} N_{iu} V_{iw}^* - N_{iw} V_{iw}^* \right)
\end{align*}
\]

\[
\begin{align*}
\gamma \chi^+ \chi^0 &= g_{g_R} \frac{g' L}{\sqrt{g^2 + g'^2}} \\
\gamma \chi^- \chi^- &= g_{g_R} \frac{g' L}{\sqrt{g^2 + g'^2}} \left( U_{iw} U_{jw}^* + \frac{1}{2} U_{id} U_{jd}^* - s_w^2 \delta_{ij} \right) \\
Z \chi^0 \chi^0 &= g_{g_R} \frac{g' L}{\sqrt{g^2 + g'^2}} \left( N_{id} N_{id}^* - N_{iu} N_{iw}^* \right) \\
W^- \chi^0 \chi^0 &= -g \left( \frac{1}{\sqrt{2}} U_{id} N_{id}^* + U_{iw} N_{iw}^* \right)
\end{align*}
\]

C Radiative corrections to the supersymmetric spectrum

C.1 Electroweak gauginos and higgsinos

We follow the approach of [20] and consider the loops involving sfermions / fermions, higgsinos or gauginos / Higgs and gauge bosons in the self energies of the gauginos and higgsinos, under the assumption that the gauge eigenstates are approximately mass states. Taking the complex phases $\phi_{M_i}$ and $\phi_{\lambda, \kappa}$ into account, we find the following corrections to the gaugino and higgsino masses:

\[
\left( \frac{\Delta M_1}{M_1} \right) = -\frac{g^2}{16\pi^2} \left\{ 11B_1(M_1, 0, M_{Q_1}) + 9B_1(M_1, 0, M_{L_1}) + B_1(M_1, \mu, M_A) + B_1(M_1, \mu, M_Z) \right. \\
+ \frac{\mu}{M_1} \sin2\beta \cos(\phi_{M_1} + \phi_{\lambda}) \left[ B_0(M_1, \mu, M_A) - B_0(M_1, \mu, M_Z) \right] \}
\]

\[
\left( \frac{\Delta M_2}{M_2} \right) = -\frac{g^2}{16\pi^2} \left\{ 9B_1(M_2, 0, M_{Q_1}) + 3B_1(M_2, 0, M_{L_1}) + B_1(M_2, \mu, M_A) + B_1(M_2, \mu, M_Z) \right. \\
+ \frac{\mu}{M_2} \sin2\beta \cos(\phi_{M_2} + \phi_{\lambda}) \left[ B_0(M_2, \mu, M_A) - B_0(M_2, \mu, M_Z) \right] \\
+ 4B_1(M_2, M_2, M_W) - 8B_0(M_2, M_2, M_W) \}
\]

\[
\left( \frac{\Delta \mu}{\mu} \right) = -\frac{3\lambda^2}{32\pi^2} \left\{ (Y_{t_1}^2 + Y_{t_2}^2)B_1(\mu, 0, M_{Q_1}) + Y_{t_1}^2 B_1(\mu, 0, M_{U_3}) + Y_{t_2}^2 B_1(\mu, \mu, M_{D_3}) \right. \\
- \frac{g^2}{64\pi^2} \left\{ 2B_1(\mu, \mu, M_Z) - 4B_0(\mu, \mu, M_Z) + B_1(\mu, M_A, M_A) + B_1(\mu, M_A, M_Z) \right. \\
+ \frac{M_1}{\mu} \sin2\beta \cos(\phi_{M_1} + \phi_{\lambda}) \left[ B_0(\mu, M_A) - B_0(\mu, M_Z) \right] \}
\]

\[
\left( \frac{\Delta m_{\tilde{g}}}{m_{\tilde{g}}} \right) = -\frac{\lambda^2}{8\pi^2} \left\{ B_1(m_{\tilde{g}}, M_A, M_A) + B_1(m_{\tilde{g}}, \mu, M_Z) \\
- \frac{m_{\tilde{g}}}{\mu} \sin2\beta \cos(\phi_{\lambda} - \phi_{\kappa}) \left[ B_0(\mu, m_{\tilde{g}}) - B_0(\mu, m_{\tilde{g}}) \right] \}
\]

We took over the notations of [20] to designate the approximate masses of the particles in the loops; note that $\mu \equiv \lambda s$ stands for the doublet higgsino mass, $m_{\tilde{g}} \equiv 2\kappa s$ for the singlino one and $m_{h_0^0, a_0^0}$ for the singlet (pseudo)scalar masses.
C.2 Sfermions

$O(\alpha_S)$ corrections to the squark masses are generated by gluon / squark and gluino / quark loops. Another source are squark self-couplings, as these receive a contribution from the $SU(3)_c$ D-term. We use the following expressions to correct the squark squared masses $m_Q^2$:

$$
\Delta m_Q^2 = -\frac{\alpha_S}{3\pi} \left\{ 2m_Q^2 \left[ B_1(m_Q, 0, m_Q) - 2B_0(m_Q, 0, m_Q) + \sum_{j=1}^{2} X_{QjL} \tilde{X}_{QjL} - X_{QjR} \tilde{X}_{QjR} \right]^2 A_0(m_Q) \right. 
+ 4 \left[ m_Q^2 B_1(m_Q, m_\tilde{g}, m_\tilde{g}) - A_0(m_\tilde{g}) - m_\tilde{g}^2 \left( 1 + 2\frac{m_\tilde{g}}{m_\tilde{g}} \Re(e^{-i\phi_3} X_{QL} \tilde{X}_{QR}) B_0(m_\tilde{Q}, m_\tilde{g}, m_\tilde{g}) \right) \right] \left\} \right.
$$

We recover the results of [40] in the CP-conserving limit.

C.3 Gluino

We follow [20] to include the $O(\alpha_S)$ corrections to the gluino mass: these involve the gluon /gluino and the quark / squark / gluino couplings. We obtain:

$$
\left( \frac{\Delta m_{\tilde{g}}}{m_{\tilde{g}}} \right) = -\frac{\alpha_S}{4\pi} \left\{ 6 \left[ B_1(m_{\tilde{g}}, m_{\tilde{g}}, 0) - 2B_0(m_{\tilde{g}}, m_{\tilde{g}}, 0) \right] 
+ \sum_{q,i=1,2} \left[ B_1(m_{\tilde{g}}, m_q, m_{\tilde{Q}_i}) + \frac{m_{\tilde{g}}}{m_\tilde{g}} \Re(e^{-i\phi_3} X_{QL} \tilde{X}_{QR}) B_0(m_{\tilde{Q}_i}, m_q, m_{\tilde{Q}_i}) \right] \right\} 
$$

D Radiative corrections to the Higgs spectrum

D.1 Wave-function renormalization

We summarize the discussion of section 3.3.1. Remember that $\mu_H = 125$ GeV replaces the external momentum.

$$
Z_{H_u} = 1 + \frac{1}{16\pi^2} \left\{ N_c Y_u^2 B_0(\mu_H, m_u, m_u) + \frac{g^2}{2} B_0(\mu_H, M_1, \mu) + \frac{3g^2}{2} B_0(\mu_H, M_2, \mu) + \lambda^2 B_0(\mu_H, \mu, m_{\tilde{g}}) 
- \sin^2 \beta \left[ g^2 B_0(\mu_H, M_W, M_W) + \frac{g^2}{2} B_0(\mu_H, M_Z, M_Z) \right] \right\} 
$$

$$
Z_{H_d} = 1 + \frac{1}{16\pi^2} \left\{ N_c Y_d^2 B_0(\mu_H, m_d, m_d) + Y_c^2 B_0(\mu_H, m_e, m_e) 
+ \frac{g^2}{2} B_0(\mu_H, M_1, \mu) + \frac{3g^2}{2} B_0(\mu_H, M_2, \mu) + \lambda^2 B_0(\mu_H, \mu, m_{\tilde{g}}) \right\} 
$$

$$
Z_S = 1 + \frac{1}{8\pi^2} \left\{ \lambda^2 B_0(\mu_H, \mu, \mu) + \kappa^2 B_0(\mu_H, m_{\tilde{g}}, m_{\tilde{g}}) \right\} 
$$

D.2 One-loop contributions to the effective potential

D.2.1 SM-fermions

The squared-bilinear matrices of the fermions of third generation have been provided in Eq.42. One observes that they split into (at-most) 2 x 2 blocks corresponding to the left-handed quark fields, the right-handed ones, the left-handed leptons and the right-handed one. The following eigenvalues can be derived:

$$
m_{t\tilde{t}}(H) = \frac{1}{2} \left[ Y_t^2 |H_u|^2 + Y_d^2 |H_d|^2 + \sqrt{Y_t^4 |H_u|^4 + Y_d^4 |H_d|^4 + 2Y_t^2 Y_d^2 (|H_u|^2 |H_d|^2 - 2|H_u \cdot H_d|)^2} \right] = m_{t\tilde{t}}^2(H)
$$

$$
m_{b\tilde{b}}(H) = \frac{1}{2} \left[ Y_b^2 |H_u|^2 + Y_d^2 |H_d|^2 - \sqrt{Y_t^4 |H_u|^4 + Y_d^4 |H_d|^4 + 2Y_t^2 Y_d^2 (|H_u|^2 |H_d|^2 - 2|H_u \cdot H_d|)^2} \right] = m_{b\tilde{b}}^2(H)
$$

$$
m_{\tau\tilde{\tau}}(H) = 0
$$

$$
m_{\tau\tilde{\tau}}(H) = Y_{\tau}^2 |H_d|^2 = m_{\tau\tilde{\tau}}^2(H)
$$

42
One can then deduce the following (non-vanishing) contributions to the Higgs mass matrices (with $N_c = 3$ the number of colors):

$$
\delta \langle M_{H^+}^2 \rangle_{11} = \Omega_f \frac{v_d}{v_u} \\
\delta \langle M_{H^+}^2 \rangle_{22} = \Omega_f \frac{v_u}{v_d} \\
\delta \langle M_{H^+}^2 \rangle_{12} = \Omega_f = \delta \langle M_{H^+}^2 \rangle_{21}
$$

We also note the following contributions to the trilinear Higgs couplings:

$$
\delta g^{S_1 S_2 S_3}_{H^+ H^0 H^0} = -\frac{N_c}{8\sqrt{2}\pi^2} \left\{ Y^2 \left[ \ln \left( \frac{Y^2 v_u}{Q^2} \right) + \frac{2}{3} \right] \left( \Pi^S \right)_{i,j,k}^{u,u,u} + Y^2 \left[ \ln \left( \frac{Y^2 v_d}{Q^2} \right) + \frac{2}{3} \right] \left( \Pi^S \right)_{i,j,k}^{d,d,d} \\
+ Y^2 \frac{\ln Y^2 v_u}{Q^2} \left( \Pi^H \right)_{i,j,k}^{u,u,u} + Y^2 \frac{\ln Y^2 v_d}{Q^2} \left( \Pi^H \right)_{i,j,k}^{d,d,d} \right\} \\
- \frac{2Y^2 Y^2 v_d v_u}{8\sqrt{2}\pi^2} \left( Y^2 v_u \sin \beta \cos \beta \left( 3 \ln \frac{Y^2 v_u^2}{Q^2} - \ln \frac{Y^2 v_d^2}{Q^2} \right) + (Y^2 v_d \sin^2 \beta + Y^2 v_d \cos^2 \beta) \left( \ln \frac{Y^2 v_d^2}{Q^2} - \frac{1}{2} \right) \right) \\
+ Y^2 \frac{Y^2 v_d^2}{Q^2} \sin \beta \cos \beta \left( 3 \ln \frac{Y^2 v_u^2}{Q^2} - \ln \frac{Y^2 v_d^2}{Q^2} \right) \left( \ln \frac{Y^2 v_d^2}{Q^2} - \frac{1}{2} \right) \right\} \\
- \frac{Y^4 v_d v_u \sin \beta \cos \beta}{8\sqrt{2}\pi^2} \ln \frac{Y^2 v_d^2}{Q^2}
$$

D.2.2 Electroweak gauge bosons

Using Eq. we obtain the following contribution to the effective potential (where we have performed an expansion in terms of the charged-Higgs fields):

$$
\delta V_H^2 = \frac{3}{64\pi^2} \left\{ \frac{(g^2 + g^2)^2}{4} \left( |H_u|^2 + |H_d|^2 \right)^2 \left[ \ln \left( \frac{g^2 + g^2}{|H_u|^2 + |H_d|^2} \right) - \frac{3}{2} \right] \\
+ \frac{g^4}{2} \left( |H_u|^2 + |H_d|^2 \right)^2 \left[ \ln \frac{g^2 |H_u|^2 + |H_d|^2}{2Q^2} - \frac{3}{2} \right] \\
+ \left[ \frac{g^2 + g^2}{2} \left( |H_u|^2 + |H_d|^2 \right) (H_u^+ H_u^- + H_d^+ H_d^-) \\
- 2g^4 \left( |H_u|^2 H_u^+ H_d^- + |H_d|^2 H_u^- H_d^+ + 2Re(H_u^+ H_d^- H_u^- H_d^+) \right) \right] \\
\times \left[ \ln \left( \frac{g^2 + g^2}{|H_u|^2 + |H_d|^2} \right) \right] \right\} \\
+ \left( \ln \frac{g^2 + g^2}{|H_u|^2 + |H_d|^2} \right) \left( H_u^+ H_u^- + H_d^+ H_d^- \right) \left[ \ln \frac{g^2 |H_u|^2 + |H_d|^2}{2Q^2} - 1 \right] + O (|H^+ H^-|^2) \right\}
$$
One derives the following (non-vanishing) contributions to the mass-matrices:

\[
\delta \langle \mathcal{M}^2_{H+} \rangle_{11} = \Omega_G v_d^2 \\
\delta \langle \mathcal{M}^2_{H+} \rangle_{22} = \Omega_G v_u^2 \\
\delta \langle \mathcal{M}^2_{H+} \rangle_{12} = \Omega_G v_d v_u \\
\Omega_G = -\frac{g^2 g^2}{32 \pi^2} v_d v_u \left[ \ln \frac{M_H^2}{Q^2} - 1 \right] \\
\bar{\Omega}_G = \frac{3}{64 \pi^2} \left[ 2g^4 \ln \frac{M_W^2}{Q^2} + (g^2 + g^2)^2 \ln \frac{M_Z^2}{Q^2} \right]
\]

Similarly, one can derive the corrections to the trilinear Higgs couplings:

\[
\delta g s_i^2 s_j^2 = \frac{3}{64 \sqrt{2} \pi^2} \left[ \left( \frac{g^2 + g^2}{2} \right)^2 \ln \frac{M_Z^2}{Q^2} + g^4 \ln \frac{M_W^2}{Q^2} \right] x \left[ (I)^{u,u,u} + (I)^{u,d,d} + (I)^{d,u,u} + (I)^{d,d,d} \right] + v_d \left[ (I)^{u,d,d} + (I)^{d,u,u} + (I)^{d,d,d} \right] + v_u \left[ (I)^{u,u,u} + 3v_d^2 v_d (I)^{d,u,u} + 3v_d^2 v_u^2 (I)^{d,d,d} + v_u^2 (I)^{d,d,d} \right]
\]

\[
\delta g s_i^2 h^+ h^- = \frac{3}{64 \sqrt{2} \pi^2} \left[ \left( \frac{g^2 - g^2}{2} \right)^2 \ln \frac{M_Z^2}{Q^2} + g^4 \ln \frac{M_W^2}{Q^2} \right] \left[ v_u X_R + v_d X_R \right]
\]

### D.2.3 Sfermions

Considering the sfermion mass-matrices of Eq.\(^\text{[39, 40, 21, 22, 30, 31]}\) and focusing on the neutral-Higgs dependence first, one obtains decoupling 2 × 2 blocks \(-1 \times 1\) in the case of the smuinos – so that eigenvalues may be expressed as \(m_{\tilde{F}_2}^2 = \frac{1}{2} T_F(H^0) + (-1)^m \sqrt{R_F(H^0)}\), \(m = 1, 2\). Corresponding contributions to the neutral Higgs mass-matrix thus read (we denote as \(E_{ijk}\) the coefficients coming from the tadpole equations – see Eq.\(^\text{[32]}\)):

\[
\delta \langle \mathcal{M}^2_{H^0} \rangle_{ij} = \frac{N_c}{64 \pi^2} \left\{ \left[ \left( \frac{g^2 + g^2}{2} \right)^2 \ln \frac{M_Z^2}{Q^2} + g^4 \ln \frac{M_W^2}{Q^2} \right] x \left[ (I)^{u,u,u} + (I)^{u,d,d} + (I)^{d,u,u} + (I)^{d,d,d} \right] + v_d \left[ (I)^{u,d,d} + (I)^{d,u,u} + (I)^{d,d,d} \right] + v_u \left[ (I)^{u,u,u} + 3v_d^2 v_d (I)^{d,u,u} + 3v_d^2 v_u^2 (I)^{d,d,d} + v_u^2 (I)^{d,d,d} \right] \right\}
\]

with:

\[
\begin{align*}
T_U &= m_{\tilde{q}}^2 + m_{\tilde{u}}^2 + 2Y_u^2 H_u^0 + \frac{g^2 + g^2}{4} (|H_u^0|^2 + |H_d^0|^2) \\
R_{U}^2 &= \left[ m_Q^2 + m_{\tilde{d}}^2 + \frac{1}{9} \left( \frac{g^2 + g^2}{3} \right) (|H_u^0|^2 + |H_d^0|^2) \right] (|H_u^0|^2 + |H_d^0|^2) + 4Y_u^2 \left[ A_u^2 |H_u^0|^2 + \lambda^2 |S|^2 |H_u^0|^2 - 2\lambda A_u \text{Re}(e^{(\varphi A_u + \varphi S)} S H_u^0 H_d^0) \right] \\
T_D &= m_{\tilde{q}}^2 + m_{\tilde{d}}^2 + 2Y_d^2 H_d^0 + \frac{g^2 + g^2}{4} (|H_u^0|^2 + |H_d^0|^2) \\
R_{D}^2 &= \left[ m_Q^2 + m_{\tilde{u}}^2 + \frac{1}{4} \left( \frac{g^2 - g^2}{3} \right) (|H_u^0|^2 + |H_d^0|^2) \right] (|H_u^0|^2 + |H_d^0|^2) + 4Y_d^2 \left[ A_d^2 |H_d^0|^2 + \lambda^2 |S|^2 |H_u^0|^2 - 2\lambda A_d \text{Re}(e^{(\varphi A_d + \varphi S)} S H_u^0 H_d^0) \right] \\
T_E &= m_{\tilde{q}}^2 + m_{\tilde{u}}^2 + 2Y_e^2 H_e^0 + \frac{g^2 + g^2}{4} (|H_u^0|^2 + |H_d^0|^2) \\
R_{E}^2 &= \left[ m_{\tilde{d}}^2 + m_{\tilde{d}}^2 + \frac{1}{4} \left( -2g^2 + g^2 \right) (|H_u^0|^2 + |H_d^0|^2) \right] (|H_u^0|^2 + |H_d^0|^2) + 4Y_e^2 \left[ A_e^2 |H_u^0|^2 + \lambda^2 |S|^2 |H_u^0|^2 - 2\lambda A_e \text{Re}(e^{(\varphi A_e + \varphi S)} S H_u^0 H_d^0) \right]
\end{align*}
\]

\[44\]
Additionally, the sneutrino mass reads: 

$$m_\nu^2 = m_H^2 - \frac{q^2 + z^2}{4} (|H_u^0|^2 - |H_d^0|^2).$$

To derive the corrections to the charged-Higgs masses and Higgs-to-Higgs couplings, one is confronted to the task of diagonalizing the matrix-system of Eq.49, 50, 51, 52, 53, 54. This can be performed perturbatively, as an expansion in the Higgs-doublet field, which amounts to a series in \( \delta \lambda \). We confine to a precision of order \( O(\delta^2) \) at the level of the masses, which means that we compute the potential up to terms of \( H^4 \)-order (\( H \) standing for any Higgs-doublet field) and freeze singlet fields to their v.e.v. s for terms of \( H^4 \)-order (they are kept explicitly for terms of lower order in the expansion). The ensuing corrections to the Higgs potential can be matched onto Eq.33 and we may then use the results of section [7,3] e.g. for the charged-Higgs mass (Eq.67) or the Higgs couplings. For squarks of each generation (note that we neglect the Yukawa couplings of the two first families):

$$\delta V_0 = \frac{N_c}{32 \pi^2} \left\{ 2 m_\nu^2 \left[ \ln \frac{m_\nu^2}{Q^2} - \frac{3}{2} \right] + m_\nu \left[ \ln \frac{m_\nu^2}{Q^2} - \frac{3}{2} \right] + m_D \left[ \ln \frac{m_D^2}{Q^2} - \frac{3}{2} \right] \right\}$$

$$\delta M_2 = \frac{2 N_c}{32 \pi^2} \left\{ \left( Y_u^2 + \frac{g^2}{6} \right) F_0(m_\nu^2) + \left( Y_d^2 + \frac{g^2}{6} \right) F_0(m_D^2) + Y_L^2 A_e^2 \tilde{F}_1(m_D^2, m_\nu^2) + Y_L^2 A_e^2 S_F(m_D^2, m_\nu^2) + Y_L^2 \lambda^2 |S|^2 \tilde{F}_1(m_D^2, m_\nu^2) \right\}$$

$$\delta \lambda = \frac{2 N_c}{32 \pi^2} \left\{ \left( Y_u^2 - Y_d^2 \right) \left( \frac{g^2}{12} + \frac{g^2}{4} \right) + 2 \left( \frac{g^2}{12} \right)^2 \right\} \ln \frac{m_\nu^2}{Q^2} + \left[ Y_u^2 - Y_d^2 \left( \frac{g^2}{12} + \frac{g^2}{4} \right) + 2 \left( \frac{g^2}{12} \right)^2 \right] \ln \frac{m_D^2}{Q^2} + \left[ Y_u^2 - Y_d^2 \left( \frac{g^2}{12} + \frac{g^2}{4} \right) + 2 \left( \frac{g^2}{12} \right)^2 \right] \ln \frac{m_D^2}{Q^2}$$
\[ \delta \lambda_5 = \frac{2N_c}{32\pi^2} \lambda^2 S^2 \left\{ V_u A_e e^{2i(\varphi_{\lambda u} + \varphi_{\lambda e})} V_r (m_{\lambda u}^2, m_{\lambda e}^2) + V_d A_d e^{2i(\varphi_{\lambda d} + \varphi_{\lambda d})} V_r (m_{\lambda d}^2, m_{\lambda d}^2) \right\} \]

\[ \delta \lambda_6 = \frac{2N_c}{32\pi^2} \lambda S \left\{ V_u A_e e^{i(\varphi_{\lambda u} + \varphi_{\lambda e})} \left[ \left( \frac{g^2 + g^2 - g^2}{12} \right) F_3(m_{\lambda u}^2, m_{\lambda u}^2) + \left( \frac{g^2 - g^2}{3} \right) F_3(m_{\lambda u}^2, m_{\lambda e}^2) + V_d A_d e^{i(\varphi_{\lambda d} + \varphi_{\lambda d})} F_3(m_{\lambda d}^2, m_{\lambda d}^2) \right] \right\} \]

\[ \delta \lambda_7 = \frac{2N_c}{32\pi^2} \lambda S \left\{ V_u A_e e^{i(\varphi_{\lambda u} + \varphi_{\lambda e})} \left[ \left( \frac{g^2 + g^2 - g^2}{12} \right) F_3(m_{\lambda u}^2, m_{\lambda u}^2) + \left( \frac{g^2 - g^2}{3} \right) F_3(m_{\lambda u}^2, m_{\lambda e}^2) + V_d A_d e^{i(\varphi_{\lambda d} + \varphi_{\lambda d})} F_3(m_{\lambda d}^2, m_{\lambda d}^2) \right] \right\} \]

For the sleptons:

\[ \delta \nu_0 = \frac{1}{32\pi^2} \left\{ 2m_{\nu_L} \left[ \ln \frac{m_{\nu_L}^2}{Q^2} - \frac{3}{2} \right] + m_{\nu_R} \left[ \ln \frac{m_{\nu_R}^2}{Q^2} - \frac{3}{2} \right] \right\} \]

\[ \delta M_{\nu_L}^2 = \frac{2}{32\pi^2} \left\{ \left[ \frac{g^2}{2} \left( F_0(m_{\nu_L}^2) - F_0(m_{\nu_R}^2) \right) + Y_{\nu_L}^2 \lambda^4 |S|^4 F_5(m_{\nu_L}^2, m_{\nu_R}^2) \right] \right\} \]

\[ \delta \lambda_{\nu_L} = \frac{2}{32\pi^2} \left\{ 2 \left[ \left( \frac{g^2}{2} \right)^2 + \left( \frac{g^2}{2} \right)^2 \right] \frac{m_{\nu_L}^2}{Q^2} \ln \frac{m_{\nu_L}^2}{Q^2} + \left( \frac{g^2}{2} \right)^2 \frac{m_{\nu_R}^2}{Q^2} \ln \frac{m_{\nu_R}^2}{Q^2} \right\} \]

\[ \delta \lambda_{\nu_R} = \frac{2}{32\pi^2} \left\{ 2 \left[ \left( \frac{g^2}{2} \right)^2 + \left( \frac{g^2}{2} \right)^2 \right] \frac{m_{\nu_L}^2}{Q^2} \ln \frac{m_{\nu_L}^2}{Q^2} + \left( \frac{g^2}{2} \right)^2 \frac{m_{\nu_R}^2}{Q^2} \ln \frac{m_{\nu_R}^2}{Q^2} - 2Y^{\nu_L} \lambda^2 |S|^4 |F_7(m_{\nu_L}^2, m_{\nu_R}^2) - Y_{\nu_R}^2 \lambda^2 |S|^4 F_7(m_{\nu_L}^2, m_{\nu_R}^2) \right\} \]

D.2.4 Charginos and neutralinos

To include the chargino and neutralino contributions to the effective Higgs potential, we turn exclusively to the method that we have just presented in the case of the fermions. In other words, we diagonalize the matrix system of Eq.33 perturbatively, in an expansion of doublet Higgs-fields and we match the ensuing potential to the form of Eq.33. One can then work out the contributions to the Higgs mass matrix and couplings. Note, however, that instead of diagonalizing directly the 9 x 9 (squared) bilinear matrix of Eq.33 it is easier to consider the dependence on neutral Higgs fields only (that is replacing charged fields by 0), as the corresponding matrix then splits into various blocks. All the couplings of Eq.33 can be identified from the neutral potential, with the exception of \( \lambda_{3,4,5} \), which only appear in terms of the sum \( \lambda_3 + \lambda_4 \). It is a straightforward task, however, to compute \( \lambda_4 \) in a second step, from the charged couplings of the full potential. Another remark accompanies the observation that, as higgsino and singlino masses depend on the singlet Higgs field, the coefficients in our matching procedure depend on the singlet fields as well (those would correspond to operators of dimension > 4), which leads to additional (but
straightforward) terms, with respect to the results of section E.3. This $S$-dependence can be neglected for terms of order $H^4$, as keeping it would produce terms of higher order in $\frac{\lambda^2}{\lambda^0}$. For $M^2_0$ and $M^2_2$, the $S$-dependence is largely absorbed (at least at leading logarithmic order) by the coefficients $\lambda^0_p$ and $\lambda^0_M$. We obtain:

$$\delta V_0 = -\frac{1}{32\pi^2} \left\{ M^2_0 \left[ \ln \frac{M^2_0}{Q^2} - \frac{3}{2} \right] + 3M^2_2 \left[ \ln \frac{M^2_2}{Q^2} - \frac{3}{2} \right] + 4(\lambda^2)^2 \left[ \ln \lambda^2 \left( \frac{S^2}{Q^2} \right) - \frac{3}{2} \right] + (4\lambda^2)^2 \left[ \ln \left( \frac{4\lambda^2 S^2}{Q^2} \right) - \frac{3}{2} \right] \right\}$$

$$\delta M^2_{0,d} = -\frac{1}{32\pi^2} \left\{ \left( g^2 F_0(M^2_0) + 3g^2 F_0(M^2_0) + (2\alpha^2 + 2^2 + 2^2) F_0(\lambda^2 S^2) + 2\alpha^2 F_0(4\lambda^2 S^2) \right) + g^2 (M^2_0 + \lambda^2 S^2) F_1(M^2_0, \lambda^2 S^2) + 3g^2 (M^2_0 + \lambda^2 S^2) F_1(M^2_0, \lambda^2 S^2) + 2\lambda^2 (4\alpha^2 + 2^2) |S|^2 \right\} F_4(4\alpha^2 |S|^2, \lambda^2 S^2) \right\}$$

$$\delta \lambda_p = -\frac{\lambda^2}{32\pi^2} \left\{ \left( g^2 \left[ \frac{\lambda^2 |S|^2}{Q^2} + F_1(M^2_0, \lambda^2 S^2) + (M^2_0 + \lambda^2 S^2) F_2(M^2_0, \lambda^2 S^2) \right) + 2\lambda^2 \left[ \frac{\lambda^2 |S|^2}{Q^2} + F_1(4\alpha^2 |S|^2, \lambda^2 S^2) + (4\alpha^2 + \lambda^2) |S|^2 F_3(4\alpha^2 |S|^2, \lambda^2 S^2) \right] \right\}$$

$$\delta A_{\omega,}\omega \rho_{\omega,\rho} = -\frac{1}{32\pi^2} \left\{ \left( 2\alpha^2 M^2_0 e^{(\omega_1 + \omega_\rho)} F_1(M^2_0, \lambda^2 |S|^2) + 3g^2 M^2_0 e^{(\omega_2 + \omega_\rho)} F_1(M^2_0, \lambda^2 |S|^2) \right) \right\}$$

$$\delta \lambda_M = -\frac{\lambda^2}{32\pi^2} \left\{ \left( g^2 \left[ \frac{\lambda^2 |S|^2}{Q^2} + F_1(M^2_0, \lambda^2 |S|^2) + (M^2_0 + \lambda^2 |S|^2) F_2(M^2_0, \lambda^2 |S|^2) \right) + 2\lambda^2 \left[ \frac{\lambda^2 |S|^2}{Q^2} + F_1(4\alpha^2 |S|^2, \lambda^2 |S|^2) + (4\alpha^2 + \lambda^2) |S|^2 F_3(4\alpha^2 |S|^2, \lambda^2 |S|^2) \right] \right\}$$

$$\delta \lambda_3 = -\frac{1}{32\pi^2} \left\{ \left( g^2 \left[ \frac{\lambda^2 |S|^2}{Q^2} + \frac{5g^2}{2} \ln \frac{M^2_0}{Q^2} + \left( 2\lambda^2 + 4\lambda^2 + 5\lambda^2 + 2^2 g^2 \right) \right] \ln \lambda^2 \left( \frac{|S|^2}{Q^2} \right) + 2\lambda^2 \ln \frac{4\lambda^2 |S|^2}{Q^2} + g^2 g^2 F_1(M^2_0, M^2_2) \right\}$$

\]

D.2.5 Higgs-to-Higgs contributions

Instead of diagonalizing the Higgs bilinear terms, we compute the Higgs self-energy (II) and tadpole (I) diagrams mediated by gauge and Higgs particles in the Feynmann gauge. We then set the external momentum to zero to determine the potential contributions to the Higgs mass matrices and substract the pure gauge effects in the Landau gauge – from the results in appendix D.2.2. Finally we identify the corrections to the $Z_3$-conserving parameters of Eq.33.

i) Pure-gauge contributions to the Higgs self-energies and tadpoles

For external neutral Higgs:

\[ \Pi^\nu_{\mathcal{S}^2 H^2} (p^2) = \frac{1}{16\pi^2} \left\{ \frac{7}{2} g^2 M_2^2 B_0(p, M_2, M_2) + \frac{g^2 + g^2}{2} M_2^2 B_0(p, M_2, M_2) \right\} \\
\times \sin^2 \beta X_{\nu_R X_{\nu_R}} + \cos^2 \beta X_{\nu_R X_{\nu_R}} + \sin \beta \cos \beta (X_{\nu_R X_{\nu_R}} + X_{\nu_R X_{\nu_R}}) \right\} \\
+ 2 \left[ g^2 A_0(M_2) + \frac{g^2 + g^2}{2} A_0(M_2) \right] \left[ X_{\nu_R X_{\nu_R}} + X_{\nu_R X_{\nu_R}} + X_{\nu_R X_{\nu_R}} + X_{\nu_R X_{\nu_R}} \right] \right\}.
\]

For an external charged Higgs (we consider only the physical state):

\[ \Pi^\nu_{H^+ H^-} (p^2) = \frac{2}{16\pi^2} \left[ g^2 A_0(M_2) + \frac{(g^2 - g^2)^2}{2(g^2 + g^2)} A_0(M_2) \right].
\]
ii) Higgs / gauge diagrams

The neutral self energy receives contributions from hybrid Higgs (Goldstone) / vector diagrams:

\[ \Pi_{S_0^H S_0^H}^{SV}(p^2) = \frac{1}{2\pi^2} \left\{ g^2 B_{SV}(p, M_W, M_W) + \frac{g^2 + g^2}{2} B_{SV}(p, M_Z, M_Z) \right\} \]

\[ \times \left\{ \sin^2 \beta X^R_{\mu, \nu} X^R_{\mu, \nu} + \cos^2 \beta X^R_{\mu, \nu} X^R_{\mu, \nu} + \sin \beta \cos \beta (X^R_{\mu, \nu} X^R_{\mu, \nu} + X^R_{\mu, \nu} X^R_{\mu, \nu}) \right\} \]

\[ + g^2 B_{SV}(p, M_H, M_W) \left[ \sin^2 \beta X^R_{\mu, \nu} X^R_{\mu, \nu} + \cos^2 \beta X^R_{\mu, \nu} X^R_{\mu, \nu} - \sin \beta \cos \beta (X^R_{\mu, \nu} X^R_{\mu, \nu} + X^R_{\mu, \nu} X^R_{\mu, \nu}) \right] \]

\[ + g^2 B_{SV}(p, m_{H^\pm}, M_W) \left[ \cos^2 \beta (X^R_{\mu, \nu} X^R_{\mu, \nu} + X^R_{\mu, \nu} X^R_{\mu, \nu}) + \sin^2 \beta (X^R_{\mu, \nu} X^R_{\mu, \nu} + X^R_{\mu, \nu} X^R_{\mu, \nu}) \right] \]

\[ + \frac{g^2 + g^2}{2} \sum_{k=1}^{5} B_{SV}(p, m_{S_k}, M_Z) \times \]

\[ (X^R_{\mu, \nu} X^R_{\mu, \nu} + X^R_{\mu, \nu} X^R_{\mu, \nu} - X^R_{\mu, \nu} X^R_{\mu, \nu} + X^R_{\mu, \nu} X^R_{\mu, \nu}) \}

For the charged Higgs self-energy:

\[ \Pi_{H^+ H^-}^{SV}(p^2) = \frac{1}{2\pi^2} \left\{ 2g^2 g^2 + g^2 + g^2 \frac{B_{SV}(p, m_{H^\pm}, 0) + (g^2 - g^2)^2}{2(g^2 + g^2)} B_{SV}(p, M_{H^\pm}, M_Z) + \frac{g^2 + g^2}{2} \sum_{k=1}^{5} B_{SV}(p, m_{S_k}, M_W) \right\} \]

\[ \times \left\{ \cos^2 \beta (X^R_{\mu, \nu} X^R_{\mu, \nu} + X^R_{\mu, \nu} X^R_{\mu, \nu}) + \sin^2 \beta (X^R_{\mu, \nu} X^R_{\mu, \nu} + X^R_{\mu, \nu} X^R_{\mu, \nu}) - \sin \beta \cos \beta (X^R_{\mu, \nu} X^R_{\mu, \nu} + X^R_{\mu, \nu} X^R_{\mu, \nu}) \right\} \]

iii) Pure Higgs loops

The loops including only Higgs bosons (including the Goldstone bosons, with mass \( M_W \) and \( M_Z \)) read:

\[ \Pi_{S_0^H S_0^H}^{S}(p^2) = \frac{1}{2\pi^2} \left\{ \sum_{m,n=1}^{2} g^2 S^0_{m} H^+_m H^-_n B_0(p, m_{H^+_m}, m_{H^-_n}) + \frac{1}{2} \sum_{m=1}^{2} g^2 S^0_{m} H^+_m H^-_n A_0(m_{H^+_m}) \right\} \]

\[ \Pi_{H^+ H^-}^{S}(p^2) = \frac{1}{2\pi^2} \left\{ \sum_{m=1}^{6} g^2 H^+ H^- H^-_m A_0(m_{H^+_m}) + \frac{1}{2} \sum_{m=1}^{6} g^2 S^0_{m} H^+_m H^-_m A_0(m_{S^0_{m}}) \right\} \]

\[ + \sum_{n=1,2}^{6} g^2 S^0_{m} H^+_m H^-_n B_0(p, m_{S^0_{n}}, m_{H^-_n}) \]

\[ T_{S_0^H}^{S} = \frac{1}{2\pi^2} \sum_{m=1}^{2} g^2 S^0_{m} H^+_m H^-_n A_0(m_{H^+_m}) + \frac{1}{2} \sum_{m=1}^{2} g^2 S^0_{m} S^0_{n} A_0(m_{S^0_{m}}) \]

where the Higgs-to-Higgs couplings can be found in appendix B.2.3.

iv) Contributions to the Higgs mass-matrices

Since we are interested in the contributions from the effective potential, we take the limit \( p^2 = 0 \), which simply induces the replacement \( B_0(p, m, M) \rightarrow -F_1(m^2, M^2) \). The contribution to the mass matrices of the Higgs states reads:

\[ \delta \langle M_{H^0}^2 \rangle_{ij} = - \left[ \Pi_{S_0^H S_0^H}^{V+SV+S}(0) - E_{ijk} T_{S_0^H}^{V+SV+S} \right] \]

\[ \delta m_{H^\pm}^2 = - \left[ \Pi_{H^+ H^-}^{V+SV+S}(0) - \cos^2 \beta T_{H^0}^{V+SV+S} \right] \]

where the coefficients \( E_{ijk} \) are the same as in appendix D.2.3 that is, they correspond to the tadpole coefficients of Eq.32.

v) Reconstruction of the Higgs contributions to the potential

After subtracting the pure gauge contributions from appendix D.2.2, one can reconstruct the \( Z_2 \)-conserving parameters of the potential of Eq.33 induced by Higgs corrections. We start by rotating away the neutral Goldstone
boson, obtaining thus a $5 \times 5$ matrix for the Higgs corrections to the neutral Higgs mass-matrix: $\delta \left( \tilde{M}_{H^0}^2 \right)_{ij}$. We then employ the method that was outlined in [25]:

$$\delta A_S \cos \varphi_2 = -\frac{1}{3s} \left\{ \delta \left( \tilde{M}_{H^0}^2 \right)_{55} + \frac{v}{s} \sin 2\beta \left[ \frac{1}{2} \delta \left( \tilde{M}_{H^0}^2 \right)_{45} - \frac{v}{s} \sin 2\beta \delta \left( \tilde{M}_{H^0}^2 \right)_{44} \right] \right\}$$

$$\delta V_0(|S|^2) = \frac{1}{4s^2} \left\{ \frac{1}{3} \delta \left( \tilde{M}_{H^0}^2 \right)_{33} + \frac{1}{3} \delta \left( \tilde{M}_{H^0}^2 \right)_{55} - \frac{v}{s} \sin 2\beta \delta \left( \tilde{M}_{H^0}^2 \right)_{44} \right\} |S|^4$$

$$\delta A_{ud} \cos \varphi_{A_{ud}} = \frac{1}{3sv \sqrt{2}} \left\{ \frac{1}{3} \delta \left( \tilde{M}_{H^0}^2 \right)_{45} + \frac{v}{s} \sin 2\beta \delta \left( \tilde{M}_{H^0}^2 \right)_{44} \right\}$$

$$\delta \lambda_2^M \cos \varphi_M = -\frac{1}{3sv} \left\{ \frac{1}{3} \delta \left( \tilde{M}_{H^0}^2 \right)_{45} - \frac{v}{s} \sin 2\beta \delta \left( \tilde{M}_{H^0}^2 \right)_{44} \right\}$$

$$\delta \lambda_2^M \sin \varphi_M = \frac{2}{3sv^2 \sin 2\beta} \left\{ \delta \left( \tilde{M}_{H^0}^2 \right)_{35} - \frac{v}{s} \sin 2\beta \delta \left( \tilde{M}_{H^0}^2 \right)_{34} \right\}$$

$$\delta \lambda_t = \frac{1}{2sv_u} \left\{ \delta \left( \tilde{M}_{H^0}^2 \right)_{13} - \cos \beta \left[ \frac{1}{3} \delta \left( \tilde{M}_{H^0}^2 \right)_{45} - \frac{2v}{s} \sin 2\beta \delta \left( \tilde{M}_{H^0}^2 \right)_{44} \right] \right\}$$

$$\delta \lambda_t = \frac{1}{2sv_d} \left\{ \delta \left( \tilde{M}_{H^0}^2 \right)_{23} - \sin \beta \left[ \frac{1}{3} \delta \left( \tilde{M}_{H^0}^2 \right)_{45} - \frac{2v}{s} \sin 2\beta \delta \left( \tilde{M}_{H^0}^2 \right)_{44} \right] \right\}$$

$$\delta \lambda_u = \frac{1}{2v_t} \left\{ \delta \left( \tilde{M}_{H^0}^2 \right)_{11} - \cos^2 \beta \delta \left( \tilde{M}_{H^0}^2 \right)_{44} \right\}$$

$$\delta \lambda_d = \frac{1}{2v_t} \left\{ \delta \left( \tilde{M}_{H^0}^2 \right)_{22} - \sin^2 \beta \delta \left( \tilde{M}_{H^0}^2 \right)_{44} \right\}$$

$$\delta \lambda_3 = \frac{1}{2v_t} \left\{ \delta \left( \tilde{M}_{H^0}^2 \right)_{12} + \sin 2\beta \left[ \delta m^2_{H^0} - \frac{1}{2} \delta \left( \tilde{M}_{H^0}^2 \right)_{44} \right] \right\}$$

$$\delta \lambda_4 = \frac{1}{v_t^2} \left\{ \delta \left( \tilde{M}_{H^0}^2 \right)_{44} - \delta m^2_{H^0} \right\}$$

### D.3 Leading two-loop effects $O(Y_t^6, Y_t^4 \alpha(S))$

We follow [22]:

$$\delta \lambda_u = \frac{3Y_t^4}{256\pi^4} \left\{ \left[ 16g_t^2 + \frac{4}{3} g^2 - 3 \sin^2 \beta Y_t^2 + 3 \cos^2 \beta Y_t^2 \right] \ln^2 \frac{Q^2}{m_t^2} \right. \right.$$  

$$\left. + \left[ 3 \cos^2 \beta Y_t^2 + (3 \cos^2 \beta + 1) Y_t^2 \right] \left( \ln^2 \frac{M_A^2}{m_t^2} - \ln^2 \frac{Q^2}{m_t^2} \right) \right\}$$

$$\delta \lambda_d = \frac{3Y_t^4}{256\pi^4} \left\{ \left[ 16g_t^2 - \frac{2}{3} g^2 + 3 \sin^2 \beta Y_t^2 - 3 \cos^2 \beta Y_t^2 \right] \ln^2 \frac{Q^2}{m_t^2} \right. \right.$$  

$$\left. + \left[ 3 \sin^2 \beta Y_t^2 + (3 \sin^2 \beta + 1) Y_t^2 \right] \left( \ln^2 \frac{M_A^2}{m_t^2} - \ln^2 \frac{Q^2}{m_t^2} \right) \right\}$$

Note that these leading effects are conveyed by the SM-fermion and gauge sector, as well as the doublet Higgs sector, so that the new-physics phases do not intervene. The contribution of sfermions or gauginos is merely reduced to the cutoff $Q$ in the logarithms.

### D.4 Pole corrections

Here we compute the shifts in the Higgs self-energies, which then allow to evaluate the pole corrections to the $\overline{\text{DR}}$ Higgs masses. We use the notation $\Delta f(p^2) \equiv f(p^2) - f(0)$ for any function $f$ of the external momentum. We are still working in the Feynmann gauge.
i) Contributions from SM fermions

\[ \Delta \Pi_{\text{SM F}}(p^2) = \frac{1}{16\pi^2} \left\{ Y_u^2 \left[ (X_{iu}^R X_{ij}^R + X_{iu}^l X_{ij}^l) \Delta B_{FF}(p, m_u, m_u) \right] - 2m_u^2 (X_{iu}^R X_{ij}^R - X_{iu}^l X_{ij}^l) \Delta B_0(p, m_u, m_u) \right\} + N_d \left[ (X_{id}^R X_{ijd}^R + X_{id}^l X_{ijd}^l) \Delta B_{FF}(p, m_d, m_d) \right] + m_d^2 (X_{id}^R X_{ijd}^R - X_{id}^l X_{ijd}^l) \Delta B_0(p, m_d, m_d) \]

\[ + Y_d^2 \left[ (X_{id}^R X_{ijd}^R + X_{id}^l X_{ijd}^l) \Delta B_{FF}(p, m_e, m_e) \right] + m_e^2 (X_{id}^R X_{ijd}^R - X_{id}^l X_{ijd}^l) \Delta B_0(p, m_e, m_e) \right\} \]

\[ \Delta \Pi_{H^+ H^-}(p^2) = \frac{1}{16\pi^2} \left\{ Y_u^2 \left[ (Y_u^2 \cos^2 \beta + Y_d^2 \sin^2 \beta) \Delta B_{FF}(p, m_u, m_d) \right] - 2Y_u Y_d m_u m_d \sin 2\beta \Delta B_0(p, m_u, m_d) \right\} + Y_e^2 \sin^2 \beta \Delta B_{FF}(p, 0, m_e) \right\} \]

ii) Contributions from gauginos and higgsinos

\[ \Delta \Pi_{\text{Gau Hig}}(p^2) = \frac{1}{16\pi^2} \left\{ \frac{g^2}{2} \Delta B_{FF}(p, M_1, \mu) + \frac{3g^2}{2} \Delta B_{FF}(p, M_2, \mu) + \lambda^2 \Delta B_{FF}(p, m_z, \mu) \right\} \times (X_{iu}^R X_{ij}^R + X_{id}^R X_{ijd}^R + X_{iu}^l X_{ij}^l) \]

\[ + 2 \left[ \lambda^2 \Delta B_{FF}(p, m_z, \mu) + \kappa^2 \Delta B_{FF}(p, m_z, m_i) \right] (X_{iu}^R X_{ij}^R + X_{id}^l X_{ijd}^l) \right\} \]

\[ \Delta \Pi_{H^+ H^-}(p^2) = \frac{1}{16\pi^2} \left\{ \frac{g^2}{2} \Delta B_{FF}(p, M_1, \mu) + \frac{3g^2}{2} \Delta B_{FF}(p, M_2, \mu) + \lambda^2 \Delta B_{FF}(p, m_z, \mu) \right\} \]

iii) Contributions exclusively from the electroweak gauge sector

\[ \Delta \Pi_{\text{EWSB}}(p^2) = \frac{1}{16\pi^2} \left\{ \frac{g^2 M_W^2}{M_0} \Delta B_0(p, M_W, M_W) + \frac{g^2 + g^2}{2} \Delta B_{SS}(p, M_Z, M_Z) \right\} \times \sin^2 \beta (X_{iu}^R X_{ij}^R + \cos^2 \beta (X_{iu}^R X_{ij}^R + \sin \beta \cos \beta (X_{iu}^R X_{ij}^R + X_{id}^l X_{ijd}^l)) \right\} \]

\[ \Delta \Pi_{H^+ H^-}(p^2) = 0 \]

iv) Contributions from the gauge / Higgs diagrams

\[ \Delta \Pi_{\text{Gau Hig}}(p^2) = \frac{1}{32\pi^2} \left\{ \left[ \Delta B_{SS}(p, M_W, M_W) + \frac{g^2 + g^2}{2} \Delta B_{SS}(p, M_Z, M_Z) \right] \right\} \times \sin^2 \beta (X_{iu}^R X_{ij}^R + X_{id}^R X_{ijd}^R) \sin \beta \cos \beta (X_{iu}^R X_{ij}^R + X_{id}^R X_{ijd}^R) \right\} \]

\[ + \frac{g^2 + g^2}{2} \sum_{k=1}^{5} \Delta B_{SS}(p, m_{S_{k}^0}, M_Z) \times \left( X_{iu}^l X_{ku}^R - X_{iu}^R X_{ku}^l + X_{id}^l X_{kd}^R - X_{id}^R X_{kd}^l \right) \left( X_{iu}^l X_{ku}^R - X_{iu}^R X_{ku}^l + X_{id}^l X_{kd}^R - X_{id}^R X_{kd}^l \right) \right\} \]

\[ \Delta \Pi_{H^+ H^-}(p^2) = \frac{1}{32\pi^2} \left\{ \left[ \frac{2g^2 g^2}{g^2 + g^2} \Delta B_{SS}(p, m_{H^+}, 0) + \frac{(g^2 - g^2)^2}{2(g^2 + g^2)} \Delta B_{SS}(p, m_{H^+}, M_Z) + \frac{g^2 + g^2}{2} \sum_{k=1}^{5} \Delta B_{SS}(p, M_{S_{k}^0}, M_W) \right] \right\} \times \sin^2 \beta (X_{ku}^R X_{ku}^R + X_{kd}^R X_{kd}^R) \sin^2 \beta (X_{ku}^R X_{ku}^R + X_{kd}^R X_{kd}^R) \right\} \]

v) Contributions exclusively from the Higgs / Goldstone sector

\[ \Delta \Pi_{\text{Higgs Gld}}(p^2) = \frac{1}{16\pi^2} \left\{ \left[ \sum_{m,n=1}^{2} g_{m,n}^R h_{m,n}^R \Delta B_0(p, m_{H^+}, m_{H^+}) + \frac{1}{2} \right] \left[ \sum_{m,n=1}^{6} g_{m,n}^R g_{m,n}^R \Delta B_0(p, m_{S_{m}^0}, m_{S_{n}^0}) \right] \right\} \]

\[ \Delta \Pi_{H^+ H^-}(p^2) = \frac{1}{16\pi^2} \left\{ \sum_{m=1,6}^{n=1,2} g_{m,n}^R h_{m,n}^R \Delta B_0(p, m_{H^+}, m_{H^+}) \right\} \]
The tree-level Higgs potential (Eq. 9) matches straightforwardly on Eq. 66:

\[ \Delta \Pi^{H}_{H-H}(p^2) = \frac{1}{16\pi^2} \left\{ \sum_{m,n=1}^{2} \right\} \left[ \begin{array}{c} N_{e} g^{s^{2}C_{m}^{*}C_{n}} + g^{s^{2}C_{m}^{*}C_{n}} \Delta B_{0}(p, m_{C_{m}}, m_{C_{n}}) + N_{e} g^{s^{2}C_{m}^{*}C_{n}} \Delta B_{0}(p, m_{C_{m}}, m_{C_{n}}) \\ + g^{s^{2}C_{m}^{*}C_{n}} \Delta B_{0}(p, m_{C_{m}}, m_{C_{n}}) \end{array} \right] \]

The Higgs potential is given in appendix B.2.2.

E.1 Matching the tree-level Higgs potential

In this appendix, we study the simplified effective Higgs potential of Eq.33, or more precisely the following and slightly modified version:

\[ \tilde{V}_{eff} = -\frac{1}{2} \left( S^{2} + \frac{A_{S}}{3} \left[ e^{i\varphi_{A}} S^{3} + h.c. \right] + V_{0}(|S|^{2}) \right) \]

This simplified potential is meant as an expansion of the effective potential – see Eq.29 – up to quartic order in the doublet fields. It slightly differs from Eq.33 in that the Z₃-symmetry has been explicitly restored in the terms of the last line. Note that this way of restoring the Z₃-symmetry is just the simplest educated guess, while any additional factor \( f(|S|^{2}, S^{3}, S^{4}) \) could intervene. Therefore, the factors of \( S/s \) appearing in the last line are just chosen as such because they will provide improved results numerically. Formally however, the associated corrections will remain of subleading order in the expansion in the doublet v.e.v.’s.

E.2 Minimization conditions

\[ M_{u}^{2} = \left[ (A_{ud} \cos \varphi_{A_{ud}} + \lambda_{P} s \cos \varphi_{M}) s + 3 \lambda_{6} \cos \varphi_{6} v_{u}^{2} + \lambda_{7} \cos \varphi_{7} v_{d}^{2} \right] \frac{v_{u}}{v_{d}} = \left[ \lambda_{P} s^{2} + \lambda_{u} v_{u}^{2} + (\lambda_{3} + \lambda_{4} + \lambda_{5} \cos \varphi_{5}) v_{d}^{2} \right] \]

\[ M_{d}^{2} = \left[ (A_{ud} \cos \varphi_{A_{ud}} + \lambda_{P} s \cos \varphi_{M}) s + \lambda_{6} \cos \varphi_{6} v_{d}^{2} + 3 \lambda_{7} \cos \varphi_{7} v_{d}^{2} \right] \frac{v_{d}}{v_{u}} = \left[ \lambda_{P} s^{2} + \lambda_{d} v_{d}^{2} + (\lambda_{3} + \lambda_{4} + \lambda_{5} \cos \varphi_{5}) v_{u}^{2} \right] \]

\[ M_{s}^{2} = -\left( V_{0} \right) - A_{S} s \cos \varphi_{A_{s}} - \lambda_{5} s v_{d}^{2} - \lambda_{4} s v_{u}^{2} + \left( A_{ud} \cos \varphi_{A_{ud}} + 2 \lambda_{P} s \cos \varphi_{M} \right) \frac{v_{u}v_{d}}{s} \]

\[ A_{S} \sin \varphi_{A_{s}} = -\lambda_{4} s \sin \varphi_{M} + \frac{1}{8} \left[ \lambda_{5} \sin \varphi_{5} v_{u} v_{d} - \lambda_{6} \sin \varphi_{6} v_{u}^{2} - \lambda_{7} \sin \varphi_{7} v_{d}^{2} \right] \]

\[ A_{S} \sin \varphi_{A_{s}} = \left( A_{ud} \sin \varphi_{A_{ud}} - 2 \lambda_{P} s \sin \varphi_{M} \right) \frac{v_{u}v_{d}}{s} \approx -3 \lambda_{P} s \sin \varphi_{M} \frac{v_{u}v_{d}}{s} \]
O(\epsilon^4) terms have been neglected. \( \langle H_0^0 \rangle \equiv \frac{\partial \langle \psi \rangle}{\partial S} \bigg|_{\langle S \rangle=x^a} \).

### E.3 Higgs mass matrices

Charged Higgs in the base \((H^+_d, H^+_u)\):

\[
\langle M^2_{H^+_u} \rangle_{11} = \Omega^+_\pm \frac{\epsilon_d}{\epsilon_u}, \quad \langle M^2_{H^+_u} \rangle_{22} = \Omega^+_\pm \frac{\epsilon_u}{\epsilon_d}, \quad \langle M^2_{H^+_u} \rangle_{12} = \Omega^+_\pm = \langle M^2_{H^+_u} \rangle_{21}
\]

\[
\Omega^+_\pm \equiv \text{Re} \left( A_{ud} \cos \varphi_{A_{ud}} + \lambda^M P_s \cos \varphi_M \right) s - (\lambda_4 + \lambda_5 \cos \varphi_5) v_u v_d + \lambda_6 \cos \varphi_6 v_u^2 + \lambda_7 \cos \varphi_7 v_d^2
\]

Neutral Higgs in the base \((h^0_u, h^0_d, h^0_s, a^0_u, a^0_d, a^0_s)\); \(O(\epsilon^4)\) terms are neglected:

\[
\langle M^2_{H^0} \rangle_{11} = \left[ A_{ud} \cos \varphi_{A_{ud}} + \lambda^M P_s \cos \varphi_M \right] s - 3 \lambda_6 \cos \varphi_6 v_u^2 + \lambda_7 \cos \varphi_7 v_d^2 \frac{\epsilon_d}{\epsilon_u} + 2 \lambda_5 v_u^2
\]

\[
\langle M^2_{H^0} \rangle_{12} = - \left[ A_{ud} \cos \varphi_{A_{ud}} + \lambda^M P_s \cos \varphi_M \right] s + 3 \lambda_6 \cos \varphi_6 v_u^2 + 3 \lambda_7 \cos \varphi_7 v_d^2 \frac{\epsilon_u}{\epsilon_d} + 2 \lambda_5 v_u^2
\]

\[
\langle M^2_{H^0} \rangle_{22} = \left[ A_{ud} \cos \varphi_{A_{ud}} + \lambda^M P_s \cos \varphi_M \right] s + \lambda_6 \cos \varphi_6 v_u^2 - 3 \lambda_7 \cos \varphi_7 v_d^2 \frac{\epsilon_u}{\epsilon_d} + 2 \lambda_5 v_u^2
\]

\[
\langle M^2_{H^0} \rangle_{13} = - \left[ A_{ud} \cos \varphi_{A_{ud}} + 2 \lambda^M P_s \cos \varphi_M \right] s + \frac{1}{s} \left( 3 \lambda_6 \cos \varphi_6 v_u^2 + \lambda_7 \cos \varphi_7 v_d^2 - 2 \lambda_5 \cos \varphi_5 v_u v_d \right) v_d + 2 \lambda_5^2 s v_u
\]

\[
\langle M^2_{H^0} \rangle_{23} = - \left[ A_{ud} \cos \varphi_{A_{ud}} + 2 \lambda^M P_s \cos \varphi_M \right] s + \frac{1}{s} \left( \lambda_6 \cos \varphi_6 v_u^2 + 3 \lambda_7 \cos \varphi_7 v_d^2 - 2 \lambda_5 \cos \varphi_5 v_u v_d \right) v_u + 2 \lambda_5^2 s v_d
\]

\[
\langle M^2_{H^0} \rangle_{33} = s A_S \cos \varphi_{A_S} + 2 s^2 \langle H^0_0 \rangle + A_{ud} \cos \varphi_{A_{ud}} \frac{\epsilon_u v_d}{s}
\]

\[
\langle M^2_{H^0} \rangle_{44} = \Omega^+_0 \frac{\epsilon_d}{\epsilon_u} ; \quad \langle M^2_{H^0} \rangle_{45} = \frac{\epsilon_u}{\epsilon_d} ; \quad \langle M^2_{H^0} \rangle_{55} = \Omega^+_0 \frac{\epsilon_u}{\epsilon_d}
\]

\[
\Omega^+_0 \equiv \left[ A_{ud} \cos \varphi_{A_{ud}} + \lambda^M P_s \cos \varphi_M \right] s - 2 \lambda_5 \cos \varphi_5 v_u v_d + \lambda_6 \cos \varphi_6 v_u^2 + \lambda_7 \cos \varphi_7 v_d^2
\]

\[
\langle M^2_{H^0} \rangle_{46} = \left[ A_{ud} \cos \varphi_{A_{ud}} - 2 \lambda^M P_s \cos \varphi_M + \frac{1}{s} \left( \lambda_6 \cos \varphi_6 v_u^2 + \lambda_7 \cos \varphi_7 v_d^2 - 2 \lambda_5 \cos \varphi_5 v_u v_d \right) \right] v_d
\]

\[
\langle M^2_{H^0} \rangle_{56} = \left[ A_{ud} \cos \varphi_{A_{ud}} - 2 \lambda^M P_s \cos \varphi_M + \frac{1}{s} \left( \lambda_6 \cos \varphi_6 v_u^2 + \lambda_7 \cos \varphi_7 v_d^2 - 2 \lambda_5 \cos \varphi_5 v_u v_d \right) \right] v_u
\]

\[
\langle M^2_{H^0} \rangle_{66} = -3 s A_S \cos \varphi_{A_S} + (A_{ud} \cos \varphi_{A_{ud}} + 4 \lambda^M P_s \cos \varphi_M) \frac{\epsilon_u v_d}{s}
\]

\[
\langle M^2_{H^0} \rangle_{14} = (2 \lambda_6 \sin \varphi_6 v_u - \lambda_5 \sin \varphi_5 v_d) v_d
\]

\[
\langle M^2_{H^0} \rangle_{15} = (2 \lambda_6 \sin \varphi_6 v_u - \lambda_5 \sin \varphi_5 v_d) v_u
\]

\[
\langle M^2_{H^0} \rangle_{16} = \left[ -3 \lambda^M P_s \sin \varphi_M + \frac{1}{s} \left( 2 \lambda_6 \sin \varphi_6 v_u^2 - \lambda_5 \sin \varphi_5 v_u v_d \right) \right] v_d
\]

\[
\langle M^2_{H^0} \rangle_{24} = (2 \lambda_7 \sin \varphi_7 v_d - \lambda_5 \sin \varphi_5 v_u) v_d
\]

\[
\langle M^2_{H^0} \rangle_{25} = (2 \lambda_7 \sin \varphi_7 v_d - \lambda_5 \sin \varphi_5 v_u) v_u
\]

\[
\langle M^2_{H^0} \rangle_{26} = \left[ -3 \lambda^M P_s \sin \varphi_M + \frac{1}{s} \left( 2 \lambda_6 \sin \varphi_7 v_u^2 - \lambda_5 \sin \varphi_5 v_u v_d \right) \right] v_u
\]

\[
\langle M^2_{H^0} \rangle_{34} = u_d \left[ \lambda^M P_s \sin \varphi_M - \frac{\epsilon_u v_d}{s} \lambda_5 \sin \varphi_5 \right]
\]

\[
\langle M^2_{H^0} \rangle_{35} = u_u \left[ \lambda^M P_s \sin \varphi_M - \frac{\epsilon_u v_d}{s} \lambda_5 \sin \varphi_5 \right]
\]

\[
\langle M^2_{H^0} \rangle_{36} = 4 \lambda^M P_s \sin \varphi_M u_d v_d
\]
E.4 Trilinear Higgs couplings

\[ g_{\phi \beta H H} = \frac{1}{\sqrt{2}} \left\{ \lambda_\mu v_u \left[ (\Pi_S)^{u,u,u}_{i,j,k} + (\Pi_A)^{u,u,u}_{i,j,k} \right] + \lambda_\rho v_d \left[ (\Pi_S)^{d,d,d}_{i,j,k} + (\Pi_A)^{d,d,d}_{i,j,k} \right] \\
