(Dated: May 11, 2014)

Lepton flavor-violating processes offer interesting possibilities to probe new physics at multi-TeV scale. We discuss those in the framework of effective field theory, emphasizing the role of gluonic operators. Those operators are obtained by integrating out heavy quarks that are not kinematically accessible at the scale where low-energy experiments take place and make those experiments sensitive to the couplings of lepton flavor changing neutral currents to heavy quarks. We discuss constraints on the Wilson coefficients of those operators from the muon conversion and from lepton flavor-violating tau decays with one or two hadrons in the final state, e.g. $\tau \rightarrow \ell \eta^{(0)}$ and $\tau \rightarrow \ell \pi^{+}\pi^{-}$ with $\ell = \mu, e$. To illustrate the results we discuss explicit examples of constraining parameters of leptoquark models.

I. INTRODUCTION

As follows from observations of neutrino oscillations, there is a good evidence that the individual lepton flavor is not conserved. Explicit calculations of the standard model (SM) rates for the charged lepton-flavor violating (LFV) transitions indicate that those are tiny\textsuperscript{[1,2]}, well beyond the capabilities of current and currently planned experiments. Yet, many models of beyond the standard model (BSM) physics do not exclude relatively large rates for such transitions, so experimental and theoretical studies of LFV processes like $\mu \rightarrow e\gamma, \tau \rightarrow \eta^{(0)}\mu$ or $\mu^{-} + (A,Z) \rightarrow e^{-} + (A,Z)$ and from lepton flavor-violating tau decays with one or two hadrons in the final state, could provide a sensitive test of those BSM schemes.

The language of effective field theory (EFT) is very useful in the studies of flavor violating processes for several reasons. First, it allows to probe the new physics (NP) scale generically, without specifying a particular model of NP. Studies of specific models in this framework are equivalent to specifying Wilson coefficients of effective operators. Second, EFT allows for studies of relative contributions of various operators and may even provide clues as to what experiments need to be done to discriminate among different possible models of new physics\textsuperscript{[3]}. Interactions of flavor-changing neutral currents (FCNC) of leptons with hadrons, either in muon conversion or in tau or meson decays can be described in terms of effective operators of increasing dimension\textsuperscript{[3]}. In order to set up an EFT calculation, however, one must first discuss the multitude of scales present in lepton FCNC transitions. The highest scale, which we denote as $\Lambda$, is the scale associated with new physics that generates the FCNC interaction. There could be many ways to generate the flavor-changing neutral current of leptons, yet, below the scale $\Lambda$ any heavy new physics particles are integrated out resulting only in a few effective operators\textsuperscript{[3]}. We shall keep track of the leading contribution due to NP which, below the scale $\Lambda$, is proportional to $1/\Lambda^2$. The second highest scale is the one associated with electroweak symmetry breaking, $v$. The most important scales for this study are the scales associated with heavy quark masses, $m_t, m_b$, and $m_c$. In the framework of EFT one must integrate out heavy quarks that are not kinematically accessible at the scale where the experiment takes place, resulting in changes of Wilson coefficients of quark and gluon operators. The relation between all those scales can be done with the help of renormalization group, keeping track of which degrees of freedom are kept and which are integrated out. We shall list the most important operators for our analysis below.

A. Quark operators

The lowest dimensional local operators that contribute to lepton-flavor violating transitions without photons in the final state\textsuperscript{[3]} have operator dimension 6. There are, in general, twelve types of operators that can be constructed,

$$L^{(6)}_{\ell_1 \ell_2} = \frac{1}{\Lambda^2} \sum_{i=1}^{12} \sum_q C_i^{q-} \ell_1 \ell_2 Q_i^{q-} \ell_1 \ell_2 + \text{H.c.},$$

where $\Lambda$ is a high scale of new physics, and $C_i^{q-}$ are dimensionless Wilson coefficients. The four fermion operators can be split into three classes which we define according to their Dirac structure,

(i) scalar operators,

$$Q_1^{q-} = (\bar{\ell}_1 R \ell_2 L) (\bar{q}R qL),$$

$$Q_2^{q-} = (\bar{\ell}_1 R \ell_2 L) (\bar{q}L qR),$$

$$Q_3^{q-} = (\bar{\ell}_1 L \ell_2 R) (\bar{q}R qL),$$

$$Q_4^{q-} = (\bar{\ell}_1 L \ell_2 R) (\bar{q}L qR),$$

where $\ell (q)$ is the SM charged lepton (quark).

The scalar operators above are defined below the scale of electroweak symmetry breaking (EWSB) in the standard model as they are not invariant under electroweak $SU(2)_L$-symmetry. The proper definition of those operators above EWSB scale should include Higgs doublet...
fields $H$. The operators of Eq. (2) result from the substitution $H \rightarrow v$ and redefinition of proper Wilson coefficients [8] to scale out quark or lepton Yukawa coupling, which would result in (dimensionless) factor of $G_F m_t m_q$ in front of the scalar operators.

These mass factors properly suppress flavor-violating transitions of the first generation of quarks and leptons that are well constrained experimentally. For example, models with FCNC Higgs boson interactions often employ factors of $\sqrt{m_\ell/m_{\tau}} v$ (so called Cheng-Sher ansatz [7]) to suppress flavor-changing lepton currents, while generic leptoquark or R-parity violative supersymmetric models do not have any factors of mass, relying on the smallness of coupling constants to suppress those effects [9]. In the following we shall absorb all mass factors into the definition of Wilson coefficients $C_i^{\ell_1 \ell_2}$.

(ii) vector operators,

\begin{align}
Q_3^{\ell_1 \ell_2} &= (\bar{q}_L \gamma^\mu \ell_2 L)(\bar{q}_L \gamma^\mu q_L), \\
Q_6^{\ell_1 \ell_2} &= (\bar{q}_L \gamma^\mu \ell_2 L)(\bar{q}_R \gamma^\mu q_R), \\
Q_7^{\ell_1 \ell_2} &= (\bar{q}_R \gamma^\mu \ell_2 R)(q_L \gamma^\mu q_L), \\
Q_8^{\ell_1 \ell_2} &= (\bar{q}_R \gamma^\mu \ell_2 R)(q_R \gamma^\mu q_R),
\end{align}

and (iii) tensor operators,

\begin{align}
Q_9^{\ell_1 \ell_2} &= (\bar{q}_L \sigma^{\mu\nu} \ell_2 L)(\bar{q}_R \sigma^{\mu\nu} q_L), \\
Q_{10}^{\ell_1 \ell_2} &= (\bar{q}_L \sigma^{\mu\nu} \ell_2 L)(\bar{q}_R \sigma^{\mu\nu} q_R), \\
Q_{11}^{\ell_1 \ell_2} &= (\bar{q}_L \gamma^\mu \ell_2 R)(\bar{q}_R \sigma^{\mu\nu} q_L), \\
Q_{12}^{\ell_1 \ell_2} &= (\bar{q}_L \gamma^\mu \ell_2 R)(\bar{q}_L \sigma^{\mu\nu} q_R).
\end{align}

All quark flavors need to be considered, but the operator basis needed to describe a particular experiment could include a smaller number of operators.

### B. Gluonic operators

The low energy experiments such as muon conversion $\mu + N \rightarrow e + N'$ or tau decay $\tau \rightarrow \eta(0)\mu$ have a naturally defined scale of the order of the mass of heavier lepton. In order to write appropriate set of effective operators at that scale one must integrate out quarks with masses above that scale [10].

The flavor changing Lagrangian for the effective vertices with $\ell_1$, $\ell_2$ and two gluon external legs at the energies lower than heavy quarks masses can be written as

\begin{equation}
\mathcal{L}_{\ell_1 \ell_2}^{(7)} = \frac{1}{\Lambda^2} \sum_{i=1}^{4} c_i^{\ell_1 \ell_2} O_i^{\ell_1 \ell_2} + \text{H.c.},
\end{equation}

where $c_i$ are the Wilson coefficients, and $O_i$ are the effective operators of dimension 7:

\begin{align}
O_1^{\ell_1 \ell_2} &= \bar{q}_L \gamma^\mu C_{1\mu}^a G^a_{\mu\nu} G^{\mu\nu}, \\
O_2^{\ell_1 \ell_2} &= \bar{q}_L \gamma^\mu C_{2\mu}^a G^a_{\mu\nu} \bar{G}^{\mu\nu}, \\
O_3^{\ell_1 \ell_2} &= \bar{q}_L C_{3\mu}^a G^a_{\mu\nu}, \\
O_4^{\ell_1 \ell_2} &= \bar{q}_L C_{4\mu}^a G^a_{\mu\nu} \bar{G}^{\mu\nu},
\end{align}

where $a = 1, \ldots, 8$ is gluon color index, $\beta_L = -b\alpha_s^2/(4\pi)$ is the one-loop beta function of three flavor QCD with $b = 11 - 2n_L/3$ ($n_L = 3$ is the number of light quarks) and $\alpha_s = g_s^2/(4\pi);

G^a_{\mu\nu} = \partial_{\mu} A_{\nu}^a - \partial_{\nu} A_{\mu}^a + g_s f_{abc} A_{\mu}^b A_{\nu}^c
\end{equation}

is the gluon strength tensor, and

\begin{equation}
C_{\mu\nu}^a = \frac{1}{2} \varepsilon_{\mu\nu\alpha\beta} G^{a\alpha\beta}
\end{equation}

is the dual one. In Eq. (10) we do not include the operators with dimension higher than 7. It can be easily seen that there are no other possibilities besides the four operators in Eqs. (6).

By calculating the loop diagrams in Fig. 1 using the standard methods [10], the coefficients $c_i^{\ell_1 \ell_2}$ can be expressed through $C_i^{\ell_1 \ell_2}$ in Eq. (1) as

\begin{align}
c_1^{\ell_1 \ell_2} &= -\frac{2}{9} \sum_{q=c,b,t} \frac{I_1(m_q)}{m_q} (C_1^{\ell_1 \ell_2} + C_2^{\ell_1 \ell_2}), \\
c_2^{\ell_1 \ell_2} &= \frac{2}{9} \sum_{q=c,b,t} \frac{I_2(m_q)}{m_q} (C_1^{\ell_1 \ell_2} - C_2^{\ell_1 \ell_2}), \\
c_3^{\ell_1 \ell_2} &= -\frac{2}{9} \sum_{q=c,b,t} \frac{I_1(m_q)}{m_q} (C_3^{\ell_1 \ell_2} + C_4^{\ell_1 \ell_2}), \\
c_4^{\ell_1 \ell_2} &= \frac{2}{9} \sum_{q=c,b,t} \frac{I_2(m_q)}{m_q} (C_3^{\ell_1 \ell_2} - C_4^{\ell_1 \ell_2}),
\end{align}

where the coefficients (see Ref. [11] for $I_1$ and Appendix A at the leading order are

\begin{equation}
I_1 = \frac{1}{3}, \quad I_2 = \frac{1}{2}
\end{equation}

FIG. 1: Feynman graphs for the calculation of matching coefficients of gluonic operators. The large dots indicate the effective vertices described by Eq. (1).
Note, as previously discussed, that while the Wilson coefficients in Eqs. (9)–(12) explicitly contain factors of $1/m_q$, in many models the coefficients $C_{1}^{q_{1}l_{1}l_{2}}$ contain factors of $m_q$, which we absorbed as part of their definition. Also, we do not explicitly write out contributions to Wilson coefficients due to possible colored heavy states that are not SM quarks; those contributions would result in additive modifications of Eqs. (9)–(12). Also, in this paper, we ignored running of $c_i$ in between different scales.

Integrating out heavy particles could also result in higher dimensional gluonic operators, as would happen for vector-like dimension-6 operators. For instance, a set of operators of dimension 8 can be written as

$$O_1^{(8)} = e^{\mu\nu\alpha\beta} (\bar{\ell}_L \partial_\mu \gamma_\nu \ell_2 L) \frac{\beta_L}{4\alpha_s} G_{\alpha\rho} G_{\beta}^{\rho}$$

$$O_2^{(8)} = e^{\mu\nu\alpha\beta} (\bar{\ell}_L \partial_\mu \gamma_\nu \ell_2 L) \frac{\beta_L}{4\alpha_s} G_{\mu}^{\alpha} G_{\beta}^{\rho}$$

$$O_3^{(8)} = (\bar{\ell}_L \partial_\mu \gamma_\nu \ell_2 L) \frac{\beta_L}{4\alpha_s} G_{\rho\alpha} G_{\mu\beta}$$ (14)

Another three operators, $O_4^{(8)} - O_6^{(8)}$, could be obtained by substituting left-handed lepton fields with the right-handed ones. Here we shall concentrate on the operators of dimension 7, leaving analysis of higher-dimensional operators for future work.

This paper is organized as follows. In section II we reexamine constraints on the Wilson coefficients of operators $O_1^{\mu}$ and $O_3^{\mu}$ from $\mu$-e conversion data. We consider constraints on Wilson coefficients of operators $O_1^{\mu} - O_2^{\mu}$ from tau decays in section III. As an example, in section IV we consider how our constraints translate into constraints on couplings of LFV lepton currents with heavy quarks in leptoquark models. We conclude in section V.

II. CONSTRAINTS FROM $\mu$-e CONVERSION

Muon conversion on a nucleus [2, 12, 17] offers a sensitive probe of new physics and a nice possibility to study it experimentally providing an interesting interplay of particle and nuclear physics effects. The number of relevant operators in Eqs. (1) and (2) is reduced if one only considers coherent $\mu + N \rightarrow e + N$ transitions$^1$ [3].

The initial state in the $\mu$-e conversion process

$$\mu^- + (A, Z) \rightarrow e^- + (A, Z)' \quad \text{(15)}$$

is the 1s state of the muonic atom with the binding energy $E_b$, and the final electron state is the eigenstate with the energy $m_e - E_b$ (neglecting the atomic recoil energy of a muonic atom, see [19]). Following Ref. [20] the $\mu$-e conversion amplitude can be written as

$$M_{N^N'}^{\mu e} = \frac{1}{\lambda^2} \int d^3x \left[ c_1 \bar{\psi}_{1s}^{\mu}(x) g_{L} P_L \psi_{1s}^{(\mu)}(x) + c_3 \bar{\psi}_{1s}^{\mu}(x) g_{R} P_R \psi_{1s}^{(\mu)}(x) \right]$$

$$\times \langle N' \mid \frac{\beta_L}{4\alpha_s} G_{\mu\nu} G_{\nu\mu} \mid N \rangle,$$ (16)

where $\langle N' \rangle$ and $|N\rangle$ are the final and initial states of the nucleus, respectively; the 1s initial muon wave function

$$\psi_{1s}(\mu) = \left( \begin{array}{c} g_{\mu} \chi_{1-}^{\pm 1/2} \\ i f_{\mu} \chi_{1+}^{\pm 1/2} \end{array} \right)$$ (17)

is normalized to 1 and corresponds to the quantum numbers $\kappa = -1$ and $\mu = \pm 1/2$ of the operators

$$K = \left( \begin{array}{cc} \sigma \cdot l + 1 & 0 \\ 0 & - (\sigma \cdot l + 1) \end{array} \right)$$ (18)

and $j_z$, respectively, where $l$ is the orbital angular momentum; and $\kappa = \pm 1$ final electron wave functions

$$\psi_{-1,W}^{\pm 1/2} = \left( \begin{array}{c} g_{e} \chi_{1-}^{\pm 1/2} \\ i f_{e} \chi_{1+}^{\pm 1/2} \end{array} \right)$$ (19)

and

$$\psi_{1,W}^{\pm 1/2} = \left( \begin{array}{c} g_{+}^{\chi} \chi_{1+}^{\pm 1/2} \\ i f_{+}^{\chi} \chi_{1-}^{\pm 1/2} \end{array} \right)$$ (20)

are normalized as

$$\int d^3x \bar{\psi}_{1,W}^{\mu}(x) \psi_{\kappa,W}^{\mu}(x) = 2 \pi \delta_{\mu\mu'} \delta_{\kappa\kappa'} \delta(W-W')$$ (21)

where $W$ is the energy. The electron mass was neglected in Eqs. (19) and (20) so that $g_{e} = i f_{e}$ and $i f_{e} = g_{e}$. Using the normalization

$$\int_{-1}^{1} d \cos \theta \int_{0}^{2\pi} d \phi \chi_{\kappa}^{\mu*} \chi_{\kappa'}^{\mu'} = \delta_{\mu\mu'} \delta_{\kappa\kappa'}$$ (22)

of the eigenfunctions $\chi_{\kappa}^{\mu}$ of $(\sigma \cdot l + 1)$ and $j_z$, we have

$$\bar{\psi}_{-1,W}^{\mu} P_L \psi_{1s}^{(\mu)} = \frac{1}{2} \left( g_{e} g_{\mu} - f_{e} f_{\mu} \right)$$

$$= \psi_{1,W}^{\mu} P_R \psi_{1s}^{(\mu)}, \quad \text{(23)}$$

$$\bar{\psi}_{1,W}^{\mu} P_L \psi_{1s}^{(\mu)} = - \frac{1}{2} \left( g_{e} g_{\mu} - f_{e} f_{\mu} \right)$$ (24)

with $\alpha = L, R$.

The pseudoscalar nucleon current couples to the nuclear spin leading to incoherent contribution [21].

$^1$ There are also important non-local contributions from the operators governing $\mu \rightarrow e \gamma$ transitions with the photon attached to a nucleus. Those contributions are well known [18] and will not be discussed here.
matrix element in Eq. [14] relevant to the coherent conversion process \((N = N')\) can be expressed by the proton \(\rho(p)\) and neutron \(\rho(n)\) densities in a nucleus as

\[
\langle N | \frac{\beta L}{4\alpha_s} G_{\mu\nu} G^{\mu\nu} | N \rangle = -\frac{9}{2} Z G^{(g,n)}(A - Z) G^{(g,n)}(\rho(n)),
\]

where \(A\) and \(Z\) represent mass and atomic number of the nucleus, and the matrix element of gluon operator between the nucleon states is defined as

\[
G^{(g,N)} = \langle N | \frac{\alpha_s}{4\pi} G_{\mu\nu} G^{\mu\nu} | N \rangle
\]

with \(N = n, p\). This scalar matrix element can be calculated by using the trace of the energy-momentum tensor \(\Theta_{\mu}^{\nu}\) and applying the flavor \(SU(3)\) symmetry. Since \(\Theta_{\mu}^{\nu}\) is flavor symmetric, the proton and neutron scalar matrix elements are equal. For the strange-quark sigma term \(\sigma_\pi = m_\pi(\bar{s}s + \bar{p}p) = 50\text{ MeV}\) the numerical result is \(G^{(g,n)} = -189\text{ MeV}\) [23].

The nucleon densities are assumed spherically symmetric and normalized as

\[
\int_0^\infty dr 4\pi r^2 \rho(N)(r) = 1.
\]

As usual for spherical nuclei, the two-parameter Fermi (2pF) charge distribution is used

\[
\rho(r) = \frac{\rho_0}{1 + \exp[(r - c)/\alpha]}.
\]

where \(c\) is the half-density radius.

The formula for the coherent conversion rate can be written as

\[
\Gamma_{\text{conv}}(\mu N \rightarrow e N) = \frac{4}{\Lambda^4} (|c_1|^2 + |c_2|^2) a_N^2,
\]

where

\[
a_N = G^{(g,p)} S^{(p)} + G^{(g,n)} S^{(n)}.
\]

The overlap integrals are defined as [20]

\[
S^{(p)} = \frac{1}{2\sqrt{2}} \int_0^\infty dr r^2 Z \rho(p)(g_{\mu} g_{\mu} - f_{\mu} f_{\mu});
\]

\[
S^{(n)} = \frac{1}{2\sqrt{2}} \int_0^\infty dr r^2 (A - Z) \rho(n)(g_{\mu} g_{\mu} - f_{\mu} f_{\mu}).
\]

The parameters of model 2pF of nucleon densities in Eq. [25] [24], and the overlap integrals in Eqs. [31] and [32] [20] for the same distributions

\[
\rho(p)(r) = \rho(n)(r) \equiv \rho(r)
\]

of neutrons and protons in the nuclei \(^{48}\text{Ti}\) and \(^{197}\text{Au}\) are shown in Table I. The parameters of the Fourier-Bessel

| Nucleus | Model | \(c\) fm | \(z\) fm | \(S^{(p)}\) | \(S^{(n)}\) |
|---------|-------|---------|---------|---------|---------|
| \(^{48}\text{Ti}\) | FB | - | - | 0.0368 | 0.0435 |
| \(^{197}\text{Au}\) | 2pF | 6.38 | 0.535 | 0.0614 | 0.0918 |

expansion (FB)

\[
\rho(r) = \left\{ \begin{array}{ll}
\sum_0 a_n \sin(v\pi r R^{-1})/(v\pi r R^{-1}) & \text{for } r \leq R \\
0 & \text{for } r > R
\end{array} \right.
\]

are given in Ref. [24, 22].

The branching ratio for \(\mu-e\) conversion on a nucleus \(N\) is defined as

\[
B_{\mu e}^N \equiv \Gamma_{\text{conv}}(\mu^- \rightarrow e^- N_{g.s.})/\Gamma_{\text{capt}}(\mu^- N),
\]

where g.s. stands for ground state. The SM muon capture rates [20, 26], the upper bounds on \(B_{\mu e}^N\), and the binding energies of \(^{48}\text{Ti}\) and \(^{197}\text{Au}\) are given in Table II with the respective references. The upper bounds on the parameters of the Lagrangian in Eq. [5] for one nonzero coefficient \(c\) at a time are given in Table I. It shows that the bound on \(\mu-e\) conversion rate on gold gives the best limit (see also Ref. [27]).

| Nucleus | \(\Gamma_{\text{capt}}(\mu^- N), s^{-1}\) | \(B_{\mu e}^N\) (90\% C.L.) | \(E_b, \text{MeV}\) |
|---------|------------------|------------------|--------|
| \(^{48}\text{Ti}\) | 2.59 \times 10^6 | 4.3 \times 10^{-12} Ref. [28] | 1.25 Ref. [29] |
| \(^{197}\text{Au}\) | 13.07 \times 10^6 | 7 \times 10^{-13} Ref. [19] | 10.08 Ref. [19] |

### III. CONSTRAINTS FROM \(\tau\) DECAYS.

The analysis presented above only deals with experimentally-interesting coherent \(\mu-e\) conversion. As a result, no parity-violating operator give any contribution to the experimental transition rates. Moreover, we had to resort to models to describe nuclear effects affecting conversion rates. It might be advantageous to use other experimental observables to study LFV new physics couplings to heavy quarks via gluonic operators. LFV tau decays offer such opportunity. Besides, analyses of tau decays have different theoretical uncertainties than muon conversion calculations; in fact, one can use chiral symmetry and low energy theorems to provide model-independent evaluations of operator matrix
elements. While the tau decays have been studied in a variety of models \([8]\), to the best of our knowledge gluonic operator contribution (and thus constraints on heavy quark couplings from those decays) has not been previously considered. In what follows we shall use tau decays to constrain matrix elements of gluonic operators.

### A. Parity-conserving gluonic operators

Complimentary to muon conversion experiments considered in section[11] parity-conserving operators can also be probed in lepton-flavor-violating tau decays \(\tau \to \ell M^+ M^-\), where \(\ell = \mu, e\) and \(M = \pi, \eta, K\) [30] [31]. In what follows, let us concentrate on the case of three-body decays \(\tau \to \mu \pi^+\pi^-\) and \(\tau \to \mu K^+ K^-\), which are the most interesting experimentally since all the final particles are charged. Transitions to other states (like \(\tau \to \ell \eta\)) can be obtained by employing flavor SU(3) symmetry relations.

In order to constrain the Wilson coefficients of the operators in Eq. (2), Eq. (3), and Eq. (4) one needs to constrain hadronic matrix elements. For the scalar operators we shall follow [30] to state

\[
\langle \pi^+\pi^- | \bar{q}q | 0 \rangle = \langle K^+ K^- | \bar{q}q | 0 \rangle = 3^M B_0, \tag{36}
\]

where for charged final states \(3^M = 1\) if the flavor of the quark field \(q\) in the operator matches the flavor content of the meson and zero otherwise. For example, \(\langle K^+ K^- | ss | 0 \rangle = \langle K^+ K^- | uu | 0 \rangle = B_0\), while \(\langle K^+ K^- | dd | 0 \rangle = 0\). Matrix elements for other light final states can be related to Eq. (36) via flavor SU(3) relations [30], e.g.,

\[
3\langle \eta \eta | \bar{u}u | 0 \rangle = \frac{3}{4} \langle \eta \eta | \bar{q}q | 0 \rangle = B_0. \tag{37}
\]

Note that \(B_0 = 1.96\) GeV can be estimated from the chiral Lagrangian relations, \(m_\pi^2 = (m_u + m_d) B_0\) assuming that \(m_u = m_d = 5\) MeV.

For the vector operators Eq. (3) one can use the definition of the pion (kaon) form factor and crossing symmetry,

\[
\langle M^+ M^- | q\gamma_\mu q | 0 \rangle = \delta^M G^{(q)}_M(Q^2) (p_+ - p_-)_\mu, \tag{38}
\]

where \(Q = p_+ - p_-\) is the momentum transfer to the hadronic system and \(p_\pm\) are the 4-momenta of \(M^\pm\). Note that \(G^{(q)}_M(0) = 1\) [32]. Just like before, flavor content of the operators should match that of the final state mesons.

The matrix elements of gluonic operators Eq. (6) are easiest estimated in the chiral limit, where \(m_u = m_d = m_s = m_M = 0\). In that limit, a low-energy theorem states that

\[
\langle M^+ M^- | \alpha_\ell B_{\mu\nu} | q^{(q)} | 0 \rangle = | \alpha_\ell | G^{(q)}_{\mu\nu} B_0 = -\frac{2}{a} q^2, \tag{39}
\]

We do not expect the results to change much away from the chiral limit, so shall use this estimate in what follows. It is these operators that we are most interested in the paper. Finally, parity invariance of strong interactions implies that

\[
\langle M^+ M^- | \bar{q}q | 0 \rangle = \langle M^+ M^- | \bar{q}q | 0 \rangle = 0. \tag{40}
\]

With the definitions above one can calculate the differential decay rate for the decay \(\tau \to \ell M^+ M^-\). For the scalar and gluonic operators one has

\[
d\Gamma(\tau \to \ell M^+ M^-) = \frac{m_\tau}{32(2\pi)^3 m_M} \left[ |A_{MM}|^2 + |B_{MM}|^2 \right] \times \left( 1 - \frac{4m_\tau^2}{q^2} \right)^2, \tag{41}
\]

where we set \(m_\ell = 0\) and defined

\[
A_{MM} = -\frac{2c_\ell^\tau}{9} q^2 + \frac{1}{2} \sum_{q=u,d,s} (C^q_{\ell\tau} + C^q_{\ell\tau}) \delta^M B_0, \tag{42}
\]

\[
B_{MM} = -\frac{2c_\ell^\tau}{9} q^2 + \frac{1}{2} \sum_{q=u,d,s} (C^q_{\ell\tau} + C^q_{\ell\tau}) \delta^M B_0. \tag{42}
\]

Integrating Eq. (41) we obtain constraints on \(c_\ell^\tau\) and \(c_\ell^\tau\) listed in Table III. Finally, for completion, we present the contribution to the differential decay rate due to vector operators,

\[
d\Gamma_V(\tau \to \ell M^+ M^-) = \frac{m_\tau^3}{308\pi^3 m_M^4} \left[ |C_{MM}|^2 + |D_{MM}|^2 \right] \times \left( 1 - \frac{4m_\tau^2}{q^2} \right)^{3/2} \left[ 1 - \frac{q^2}{m_M^2} \right]^2 \left( 1 - \frac{q^2}{m_M^2} \right), \tag{43}
\]

where we set \(m_\ell = 0\) and defined

\[
C_{MM} = \frac{1}{2} \sum_{q=u,d,s} (C^q_{\ell\tau} + C^q_{\ell\tau}) \delta^M G_M, \tag{44}
\]

\[
D_{MM} = \frac{1}{2} \sum_{q=u,d,s} (C^q_{\ell\tau} + C^q_{\ell\tau}) \delta^M G_M. \tag{44}
\]

This result could be used to constrain Wilson coefficients of vector operators.

### TABLE III: Upper bounds on the parameters of the Lagrangian in Eq. (4) from muon conversion experiments.

| Coefficient | Bound on \(|c_\ell^\tau|^2/|A|^2\), GeV\(^{-3}\) | Conversion on 197\(^+\)T | Conversion on 197\(^{+}\)Au |
|-------------|---------------------------------|---------------------|---------------------|
| \(c_1\)    | \(5.7 \times 10^{-12}\)         | \(2.6 \times 10^{-12}\) |                     |
| \(c_2\)    | \(-\)                           | \(-\)                |                     |
| \(c_3\)    | \(5.7 \times 10^{-12}\)         | \(2.6 \times 10^{-12}\) |                     |
| \(c_4\)    | \(-\)                           | \(-\)                |                     |
where \( q \) factors defined above in the Feldmann-Kroll-Stech (FKS) tau decays, be obtained from the lepton-flavor-violating meson and the hadronic matrix elements, in the flavor basis \([35]\). Numerically, anomaly matrix \( \phi \) is especially interesting, as \( \eta \) meson contains considerable amount of “glue”, which makes it possible to constrain gluonic LFV operators resulting from integrating out heavy quarks.

To calculate the decay rates one needs to parameterize the hadronic matrix elements,

\[
\begin{align*}
\langle M(p)|\bar{q}\gamma^\mu\gamma_5 q|0\rangle &= -ib_q f_M^a p^\mu, \\
\langle M(p)|\bar{q}\gamma_5 q|0\rangle &= -ib_q h_M^a, \\
\langle M(p)|\bar{q}G^{a\mu\nu}G^a_{\mu\nu}|0\rangle &= a_M,
\end{align*}
\]

where \( q = u, d, s \), and \( b_{u,d} = 1/\sqrt{2} \), \( b_s = 1 \). The form factors defined above in the Feldmann-Kroll-Stech (FKS) mixing scheme \([34]\) are constrained for \( \eta \) and \( \eta' \) mesons to be \([35]\).

\[
\begin{align*}
&a_\eta = -\frac{m_\eta^2 - m_u^2}{2} \sin 2\phi \left( f_u b_\eta \sin \phi + f_s \cos \phi \right), \\
&a_{\eta'} = -\frac{m_{\eta'}^2 - m_d^2}{2} \sin 2\phi \left( f_d b_{\eta'} \sin \phi + f_s \cos \phi \right),
\end{align*}
\]

where \( \phi = 39.3^{+1.0}_{-0.9} \) is a mixing angle of \( \eta \) and \( \eta' \) in the flavor basis \([35]\). Numerically, anomaly matrix elements are \( a_\eta = -0.022 \pm 0.002 \) GeV\(^3\), \( a_{\eta'} = -0.057 \pm 0.002 \) GeV\(^3\). The decay constants in Eq. (45) used in numerical work are \( f_\eta^u = 108 \pm 3 \) MeV, \( f_\eta^d = 89 \pm 3 \) MeV, \( f_{\eta'}^u = -111 \pm 6 \) MeV, and \( f_{\eta'}^d = 136 \pm 6 \) MeV \([35, 36]\).

Neglecting terms of the order \( \mathcal{O}(m_{/}/m_{\tau}) \), which would change our answer to at most 5% for \( \ell = \mu \), we can write for the decay rate,

\[
\Gamma(\tau \rightarrow \mu M) = \frac{m_\tau}{8\pi A^2} \left[ |A_M|^2 + |B_M|^2 \right] \left( 1 - \frac{m_M^2}{m_\tau^2} \right)^2,
\]

where \( A_M \) and \( B_M \) are defined as

\[
\begin{align*}
A_M &= \frac{2i}{9} c_\tau a_M + \sum_{q=u,d,s} \left( C_4^{q\ell\tau} - C_3^{q\ell\tau} \right) \frac{b_q h_q^M}{4m_q} + \frac{1}{2} m_{\tau} \sum_{q=u,d,s} \left( C_5^{q\ell\tau} - C_6^{q\ell\tau} \right) b_q f_M^q (48) \\
&- \frac{1}{2} m_{\tau} \sum_{q=u,d,s} \left( C_7^{q\ell\tau} - C_8^{q\ell\tau} \right) b_q f_M^q (49) \\
&+ \frac{1}{2} m_{\tau} \sum_{q=u,d,s} \left( C_9^{q\ell\tau} - C_{10}^{q\ell\tau} \right) b_q f_M^q
\end{align*}
\]

The current experimental bounds on flavor-violating tau decays allow to put stringent constraints on Wilson coefficients \( c_\tau^{q\ell\tau} \) \([37]\). We display them in Table IV. These results, along with the ones displayed in Table III, can be translated into bounds on flavor-changing interactions of leptons with heavy quarks in particular models. As an example on how this can be done, we consider a generic leptoquark model.

IV. MODEL EXAMPLE: LEPTOQUARKS

The Wilson coefficients of effective gluonic operators that were constrained in the previous sections can be used to put bounds on parameters of operators describing lepton interactions with heavy quarks in particular models of NP. Let us provide an example of how this can be done using generic leptoquark model.

The general renormalizable, \( B \) and \( L \) conserving, and \( SU(3) \times SU(2) \times U(1) \) invariant LQ-lepton-quark interactions are given in Refs. \([38, 40]\). The relevant for our consideration scalar LQs (S) and vector LQs (V) interac-
where \(q\), \(u\) and \(d\) are doublet, singlet up and singlet down quarks, respectively; we omit flavor indexes, the subindexes 0 and 1/2 indicate down quarks, respectively; we omit flavor indexes, the subindexes 0 and 1/2 indicate up and singlet quarks, respectively.

Consider the \(\mu-e\) conversion on \({}^{197}\text{Au}\) induced by leptoquark exchange. For the values of the loop integral in Eq. (A1) we simply have

\[
I_{1}(m_{1}) = I_{1}(m_{2}) = I_{1}(m_{c}) = 0.333 \text{ since the muon mass and the binding energy of the muonic gold are much lower than } c, b \text{ and } t \text{ quark masses.}
\]

The expressions for relevant Wilson coefficients in Eq. (11) are given in Table [V] where the quark flavor indexes are \(u = u, c, t\) and \(d = d, s, b\).

We assume that only the couplings \(\lambda\) for a single quark flavor are nonzero at a time. From Eqs. (11) and (11) it follows that the best bounds for the scalar LQs (left half of the Table [V]) are relaxed by the factor \(2m_{t}/m_{b} \approx 75\) with respect to the ones for the vector LQs (right half of the Table [V]). Using the bound on \(|c_{1}|\), we have for \(e = \ell_{1}\) and \(\mu = \ell_{2}\)

\[
\frac{|\lambda^{\mu t}_{RS_{S} \lambda^{\mu t}_{L_{S0}}}|}{M^{2}_{S_{0}}} = \frac{|\lambda^{\ell_{1}t}_{RS_{S} \lambda^{\ell_{1}t}_{L_{S0}}}|}{M^{2}_{S_{1/2}}} < 2.3 \times 10^{-4} \text{ GeV}^{-2} (58)
\]

\[
\frac{|\lambda^{\mu b}_{LV_{0} \lambda^{\mu b}_{R_{V0}}}|}{M^{2}_{V_{0}}} = \frac{|\lambda^{\ell_{2}b}_{LV_{0} \lambda^{\ell_{2}b}_{R_{V0}}}|}{M^{2}_{V_{1/2}}} < 4.4 \times 10^{-6} \text{ GeV}^{-2} (59)
\]

and,

\[
\frac{|\lambda^{\ell_{1}t}_{RS_{S} \lambda^{\ell_{1}t}_{L_{S0}}}|}{M^{2}_{S_{0}}} = \frac{|\lambda^{\ell_{1}t}_{RS_{S} \lambda^{\ell_{1}t}_{L_{S0}}}|}{M^{2}_{S_{1/2}}} < 2.3 \times 10^{-4} \text{ GeV}^{-2} (60)
\]

\[
\frac{|\lambda^{\ell_{2}b}_{LV_{0} \lambda^{\ell_{2}b}_{R_{V0}}}|}{M^{2}_{V_{0}}} = \frac{|\lambda^{\ell_{2}b}_{LV_{0} \lambda^{\ell_{2}b}_{R_{V0}}}|}{M^{2}_{V_{1/2}}} < 4.4 \times 10^{-6} \text{ GeV}^{-2} (61)
\]

While for \(e = \ell_{1}\) and \(\tau = \ell_{2}\),

\[
\frac{|\lambda^{\mu t}_{RS_{S} \lambda^{\mu t}_{L_{S0}}}|}{M^{2}_{S_{0}}} = \frac{|\lambda^{\ell_{1}t}_{RS_{S} \lambda^{\ell_{1}t}_{L_{S0}}}|}{M^{2}_{S_{1/2}}} < 2.2 \times 10^{-4} \text{ GeV}^{-2} (62)
\]

\[
\frac{|\lambda^{\mu b}_{LV_{0} \lambda^{\mu b}_{R_{V0}}}|}{M^{2}_{V_{0}}} = \frac{|\lambda^{\ell_{2}b}_{LV_{0} \lambda^{\ell_{2}b}_{R_{V0}}}|}{M^{2}_{V_{1/2}}} < 2.2 \times 10^{-4} \text{ GeV}^{-2} (63)
\]

and,

\[
\frac{|\lambda^{\ell_{1}t}_{RS_{S} \lambda^{\ell_{1}t}_{L_{S0}}}|}{M^{2}_{S_{0}}} = \frac{|\lambda^{\ell_{1}t}_{RS_{S} \lambda^{\ell_{1}t}_{L_{S0}}}|}{M^{2}_{S_{1/2}}} < 2.2 \times 10^{-4} \text{ GeV}^{-2} (64)
\]

\[
\frac{|\lambda^{\ell_{2}b}_{LV_{0} \lambda^{\ell_{2}b}_{R_{V0}}}|}{M^{2}_{V_{0}}} = \frac{|\lambda^{\ell_{2}b}_{LV_{0} \lambda^{\ell_{2}b}_{R_{V0}}}|}{M^{2}_{V_{1/2}}} < 4.2 \times 10^{-6} \text{ GeV}^{-2} (65)
\]

Clearly, constraints on the coefficients of operators containing tau-lepton fields are much weaker than the ones containing muon fields. We expect those constraints to improve with new data coming from Belle II collaboration.
V. CONCLUSIONS

We considered contributions of heavy quark-induced operators to leptonic FCNC transitions. We constrained Wilson coefficients of effective gluonic operators in $\mu-e$, $\tau-\mu$, and $\tau-e$ transitions. These bounds can be used to study interactions of leptonic FCNCs with heavy quarks that are kinematically inaccessible in the described experiments. We provided an explicit example of constraints on the parameters of a generic leptoquark model.

Appendix A: Integrals

In this appendix we present the results of computation of the integrals needed to obtain the matching coefficients of gluonic operators of dimension 7. The matching coefficients can be computed to be

\[ I_1(m_q) = \lambda_q \int_0^1 dx \int_0^{1-x} dy \frac{y - 4xy}{\lambda_q - xy}, \quad \text{(A1)} \]

\[ I_2(m_q) = \lambda_q \int_0^1 dx \int_0^{1-x} dy \frac{1}{\lambda_q - xy}, \quad \text{(A2)} \]

where $\lambda_q = m_q^2/E^2$ with the process energy scale $E$. For $\lambda_q > 1/4$ they take the form

\[ I_1 = 2\lambda_q - \lambda_q(4\lambda_q - 1) \left[ Li_2 \left( \frac{1 + i\sqrt{-1 + 4\lambda_q}}{2\lambda_q} \right) \right], \quad \text{(A3)} \]

\[ + Li_2 \left( \frac{2i}{\sqrt{-1 + 4\lambda_q} - i} \right), \quad \text{(A4)} \]

\[ I_2 = \lambda_q \left[ Li_2 \left( \frac{1 + i\sqrt{-1 + 4\lambda_q}}{2\lambda_q} \right) \right], \quad \text{(A5)} \]

\[ + Li_2 \left( \frac{2i}{\sqrt{-1 + 4\lambda_q} - i} \right), \quad \text{(A6)} \]

for $\lambda_q \gg 1$ they are

\[ I_1 = \frac{1}{3} \left[ 1 + \frac{7}{120}\lambda_q^{-1} + O(\lambda_q^{-2}) \right], \quad \text{(A7)} \]

\[ I_2 = \frac{1}{2} \left[ 1 + \frac{1}{12}\lambda_q^{-1} + O(\lambda_q^{-2}) \right]. \quad \text{(A8)} \]

In this paper we use the leading order result in the $\lambda_q$-expansion.

[4] A good example of this approach can be seen in discussion of charm mixing, see, e.g., E. Golowich, J. Hewett, S. Pakvasa and A. A. Petrov, Phys. Rev. D 76, 095009 (2007) [arXiv:0705.3650 [hep-ph]].
[5] For similar approach to generate lepton flavor-violating transitions with photons in the final state see, e.g. M. Raidal and A. Santamaria, Phys. Lett. B 421, 250 (1998); K. J. Healey, A. A. Petrov and D. Zhuridov, Phys. Rev. D 87, 117301 (2013).
[6] For example, $Q_1$ operator would result from an operator of the form $(\tilde{f}_R H L_{2L}) (\tilde{q}_R H Q_L)$ (where $L_{2L}$ and $Q_L$ are the correspondingly electroweak doublets of leptons and quarks). This is a dimension 8 operator that is suppressed by two powers of the NP scale and two powers of the scale $\nu$ associated with electroweak symmetry breaking.
