We consider a generic abelian hidden sector that couples to the Standard Model only through gauge-invariant renormalizable operators. This allows the exotic Higgs boson to mix with the Standard Model Higgs boson, and the exotic abelian gauge bosons to mix with the Standard Model hypercharge gauge boson. One immediate consequence of spontaneous breaking of the hidden sector gauge group is the possible decay of the lightest Higgs boson into four fermions through intermediate exotic gauge bosons. We study the implications of this decay for Higgs boson phenomenology at the Fermilab Tevatron Collider and the CERN Large Hadron Collider. Our emphasis is on the four lepton final state.

PACS numbers:

Introduction. The fundamental theory may be significantly richer than the Standard Model (SM) world that we have directly probed. Copies of many other gauge theories may be inaccessible to us because the particles that form our bodies are not charged under them. Is there a method to explore such hidden worlds given the limited collection of charges that we can directly probe? The answer is not assured, but an opportunity can be identified \cite{12,3,4,5}.

The SM has two gauge invariant, flavor-neutral operators that are relevant (dimension < 4): the hypercharge field-strength tensor $B_{\mu\nu}$ and the SM Higgs mass operator $|\Phi_{SM}|^2$. Hidden sector (i.e., non-SM states with no SM charge) abelian gauge bosons $X$ and Higgs bosons $\Phi_H$ can couple to these operators in a gauge invariant, renormalizable manner \cite{27}:

$$X_{\mu\nu}B^{\mu\nu}, \text{ and } |\Phi_H|^2|\Phi_{SM}|^2. \quad (1)$$

These couplings give us the opportunity we are looking for to see the effects of a hidden sector by virtue of their interactions with states we can observe.

In this letter we investigate the implications for Higgs boson phenomenology of the simultaneous existence of the two operators in Eq. (1). We do not tie ourselves to any particular model of the hidden abelian sector. We note that if the kinetic mixing between the gauge bosons is large, precision electroweak and dedicated collider searches may see the effects \cite{44,45,46,47,48}. For our purposes, we only need the kinetic mixing to be non-zero and large enough to allow prompt decays of the exotic gauge boson eigenstate. We also note that the pure mixing effects of $\Phi_H$ and $\Phi_{SM}$ can be probed well by colliders \cite{12,10,11,12} even if no exotic decay modes are kinematically accessible. However, it would be more difficult in that circumstance to know what the origin is of the shift in Higgs boson phenomenology at colliders. For related discussion on the phenomenology of a hidden sector see Ref. \cite{49}.

Instead, what we focus on here is the prospect of the exotic gauge boson being sufficiently light such that the lightest Higgs boson decays into a pair of them \cite{44}. The decay of the Higgs boson into two $X$ bosons is through Higgs boson mixing. The $X$ boson will then decay into SM fermions if there is even a tiny amount of kinetic mixing, which we assume to be the case. The $X$ bosons could have competing branching fraction into other exotic states potentially leading to invisible decays or even more background-free topologies than considered here. We neglect these possibilities in order to keep our analysis simple and our assumptions to a minimum. We are particularly interested in leptonic final states. Thus, the subject of this paper is to provide the details of how $pp \rightarrow h \rightarrow XX \rightarrow l\bar{l}l\bar{l}$ is possible within this theoretical framework, and to explore the detectability of this channel at the Fermilab Tevatron and CERN LHC.

Theory framework. We consider an extra $U(1)_X$ factor in addition to the SM gauge group. The only coupling of this new gauge sector to the SM is through kinetic mixing with the hypercharge gauge boson $B_{\mu}$. The kinetic energy terms of the $U(1)_X$ gauge group are

$$\mathcal{L}^{KE}_X = -\frac{1}{4}X_{\mu\nu}X^{\mu\nu} + \frac{\chi}{2}X_{\mu\nu}B^{\mu\nu}, \quad (2)$$

where we take the parameter $\chi \ll 1$ to be consistent with precision electroweak constraints. Hats on fields imply that gauge fields do not have canonically normalized kinetic terms.

As an example, we note that heavy states that are charged under both $U(1)_Y$ and $U(1)_X$ can typically induce a $\chi$ at the loop level \cite{2} given by $\chi \sim g^4g_X/(16\pi^2) \sim 10^{-3}$. Tree-level mixing, although possible, will be absent if the $U(1)_X$ is the remnant of a spontaneously broken non-abelian gauge symmetry. If the scale of $U(1)_X$ breaking is not too far above the electroweak scale, a radiatively generated $\chi$ will be quite small. We take the $U(1)_X$ breaking VEV $\xi \sim 1 \text{ TeV}$.

We introduce a new Higgs boson $\Phi_H$ in addition to the usual SM Higgs boson $\Phi_{SM}$. Under $SU(2)_L \otimes U(1)_Y \otimes U(1)_X$ we take the representations $\Phi_{SM} : (2, 1/2, 0)$ and $\Phi_H : (1, 0, q_X)$, with $q_X$ arbitrary. The Higgs sector La-
The Higgs couplings are

\[ \mathcal{L}_h = |D_\mu \Phi_{SM}|^2 + |D_\mu H|^2 + m_{H'}^2 |H'|^2 + m_{SM}^2 |\Phi_{SM}|^2 - \lambda |\Phi_{SM}|^4 - \rho |H'|^4 - k |\Phi_{SM}|^2 |H'|^2. \]

so that \( U(1)_X \) is broken spontaneously by \( \langle \Phi_H \rangle = \xi / \sqrt{2} \), and electroweak symmetry is broken spontaneously as usual by \( \langle \Phi_{SM} \rangle = (0, v / \sqrt{2}) \).

One can diagonalize the kinetic terms by redefining \( \hat{X}_\mu, \hat{B}_\mu, \hat{B}_\mu \) with

\[ \begin{pmatrix} X_\mu \\ B_\mu \end{pmatrix} = \begin{pmatrix} \sqrt{1 - \chi^2} & 0 \\ -\chi & 1 \end{pmatrix} \begin{pmatrix} \hat{X}_\mu \\ \hat{B}_\mu \end{pmatrix} \]

The covariant derivative is then

\[ D_\mu = \partial_\mu + i (g_X Q_X + g'_Y Q_Y) X_\mu + i g_Y Q_Y B_\mu + i g T^3 W^3 \]

where \( \eta = \sqrt{1 - \chi^2} \).

After a \( GL(2, R) \) rotation to diagonalize the kinetic terms followed by an \( O(3) \) rotation to diagonalize the \( 3 \times 3 \) neutral gauge boson mass matrix, we can write the mass eigenstates as (with \( s_\chi = \sin \theta_\chi, c_\chi = \cos \theta_\chi \))

\[ \begin{pmatrix} B \\ W \end{pmatrix} = \begin{pmatrix} c_W & -s_W c_\alpha & s_W s_\alpha \\ s_W & c_W c_\alpha & -c_W s_\alpha \\ 0 & s_\alpha & c_\alpha \end{pmatrix} \begin{pmatrix} A \\ Z \\ Z' \end{pmatrix}, \]

where the usual weak mixing angle and the new gauge boson mixing angle are

\[ s_W = \frac{g'}{\sqrt{g' + g^2}}; \quad \tan (2\theta_\alpha) = -\frac{2sw_\eta}{1 - s_W^2 \eta^2 - \Delta_Z}, \]

with \( \Delta_Z = M_X^2 / M_{Z_0}^2, M_{Z_0}^2 = \xi^2 g_\chi^2 q_\chi^2, M_{Z_0}^2 = (g^2 + g'^2) v^2 / 4. M_{Z_0} \) and \( M_X \) are masses before mixing. The photon is massless (i.e., \( M_A = 0 \), and the two heavier gauge boson mass eigenvalues are

\[ M_{Z,Z'} = \frac{M_{Z_0}^2}{2} \left[ (1 + s_W^2 \eta^2 + \Delta_Z) \right. \]

\[ \pm \sqrt{(1 - s_W^2 \eta^2 - \Delta_Z)^2 + 4s_W^2 \eta^2} \left. \right], \]

valid for \( \Delta_Z < (1 - s_W^2 \eta^2) \). Since we assume that \( \eta < 1 \), mass eigenvalues are taken as \( M_Z \approx M_{Z_0} = 91.19 \text{ GeV} \) and \( M_{Z'} \approx M_X \).

The two real physical Higgs bosons \( \phi_{SM} \) and \( \phi_H \) mix after symmetry breaking, and the mass eigenstates \( h, H \) are

\[ \begin{pmatrix} \phi_{SM} \\ \phi_H \end{pmatrix} = \begin{pmatrix} c_h & s_h \\ -s_h & c_h \end{pmatrix} \begin{pmatrix} h \\ H \end{pmatrix}. \]

The mixing angle and mass eigenvalues are

\[ \tan (2\theta_h) = \frac{\kappa v \xi}{\rho \xi^2 - \lambda v^2} \]

\[ M_{h,H}^2 = (\lambda v^2 + \rho \xi^2) \pm \sqrt{(\lambda v^2 - \rho \xi^2)^2 + \kappa^2 v^2 \xi^2} \].

Although the mixing angle depends on the many unknown parameters of Eq. (3), we will treat the resulting \( \theta_h \) as an input along with the Higgs boson masses.

Now we are able to present the couplings of the \( Z' \) to various SM states.

**Fermion couplings:** Couplings to SM fermions are

\[ \bar{\psi}_f Z : \frac{i g}{c_W} [\bar{c}_a (1 - s_W t_a \eta)] \left[ T_3^f - \frac{1 - s_a \eta / s_W}{1 - s_W t_a \eta} s^f_w Q \right] \]

\[ \bar{\psi}_f Z': -i g / c_W [\bar{c}_a (t_a + \eta s_w)] \left[ T_3^f - \frac{t_a + \eta / s_W}{(t_a + \eta s_w)} s^f_w Q \right] \]

where we have used \( Q = T_3^f + Q_Y \) and \( t_a \equiv s_a / c_a \). The photon coupling is as in the SM and is not shifted.

**Triple gauge boson couplings:** Denoting the coupling relative to the corresponding SM coupling as \( R \), we find \( R_{AWW} = 1, R_{ZWW} = c_a \), and \( R_{ZW+W} = -s_a \) (the last is compared to the SM \( Z^+ W^- \) coupling). In our case, to leading order we have \( c_a \approx 1, s_a \ll 1 \).

**Higgs couplings:** The Higgs couplings are

\[ h f 

\[ h W W : 2 i c_h M_{W}^2 / v \]

\[ h ZZ : 2 i c_h M_{Z_0}^2 (c_a + \eta s_w s_a)^2 - 2 i s_h M_{Z_0}^2 / \xi \]

\[ h Z' Z' : 2 i c_h M_{Z_0}^2 (c_a + \eta s_w s_a)^2 - 2 i s_h M_{Z_0}^2 / \xi \]

\[ h Z' Z' : 2 i c_h M_{Z_0}^2 (c_a + \eta s_w s_a) (s_a + \eta s_w c_a) \]

\[ - 2 i s_h M_{Z_0}^2 / \xi \]

\[ \eta / \sqrt{1 - M_{Z'}^2 / M_{Z_0}^2} \lesssim 10^{-2}. \]

This is expected given that the fractional accuracy of EW precision measurements are at the \( 10^{-4} \) level, and in our model the deviations appear at \( O(\eta^2) \).

Fits to electroweak precision observables \cite{17} constrain the SM Higgs mass to be \( \log (M_{Higgs} / 1 \text{GeV}) = 1.93_{-0.17}^{+0.16} \). This can be turned into a constraint on our model by noting that all couplings to SM fields involving \( h \) have an additional factor of \( c_h \) while those for \( H \) have \( s_h \), which results in

\[ c_h^2 \log \left( \frac{M_h}{1 \text{GeV}} \right) + s_h^2 \log \left( \frac{M_H}{1 \text{GeV}} \right) \approx 1.93_{-0.17}^{+0.16} \]

Equivalently, one can state the constraints in terms of the \( S \) and \( T \) parameters, following the discussion in Ref. [18].
Since we do not specify the value of the heavier Higgs mass, we have the freedom to choose it such that there is minimal difficulty with precision electroweak constraints. Even if we choose a much heavier Higgs boson for our second eigenstate, there are well-known ways the theory can be augmented to be compatible with the data [15].

**Decay Branching Fractions.** We now turn to the actual decay branching fractions of the Higgs boson and $Z'$ mass eigenstate. We are particularly interested in the frequency of $h \to Z'Z'$ and the leptonic branching fractions of $Z'$.

$h \to Z'Z'$ decay: In Fig. 1 we show the $h \to Z'Z'$ branching ratio as a function of $s_h^2$ for various $M_{Z'}$ and $M_h$, with $\eta = 10^{-4}$. Benchmark points are shown in Table I.

![Branching ratio of $h \to Z'Z'$ as a function of $s_h^2$ for various $M_{Z'}$ and $M_h$, with $\eta = 10^{-4}$](image1.png)

**FIG. 1:** Branching ratio of $h \to Z'Z'$ as a function of $s_h^2$ for various $M_{Z'}$ and $M_h$, with $\eta = 10^{-4}$. Benchmark points are shown in Table I.

![Branching ratio of $Z'$ into two body final states as a function of $M_{Z'}$ with $c_h^2 = 0.5$ and $\eta = 10^{-4}$.](image2.png)

**FIG. 2:** Branching ratio of $Z'$ into two body final states as a function of $M_{Z'}$ with $c_h^2 = 0.5$ and $\eta = 10^{-4}$.

| Point  | A    | B    | C    | D    | E    | F    |
|--------|------|------|------|------|------|------|
| $(M_h, M_{Z'})$ (GeV) | 120, 5 | 120, 50 | 150, 5 | 150, 50 | 250, 5 | 250, 50 |

| Table I: Six benchmark points that we study. |
leptons with $\Delta R_{\ell^+\ell^-} < 2.5$ to ensure that they come from the same $Z'$, and for this pair, form the dilepton invariant mass $M_{\ell^+\ell^-}$. We also form the 4-lepton invariant mass $M_{\ell^+\ell^-+\gamma\gamma}$. In Fig. 3, we show 4-lepton invariant mass plots for point A at LHC and point F at Tevatron, for reference.

Based on the differential distributions, we impose the following cuts in order to maximize signal over background:

1. Basic cuts: $p_T \ell \geq 20, 10, 10$ GeV ; $|\eta| < 2.5$.
2. $\Delta R$ cut: $0.05 < \Delta R_{\ell^+\ell^-} < 2.5$.
3. $M_{ij}$ cuts: $M_{ee} = M_{\mu\mu} \pm 10$ GeV.
4. $M_{ijkl}$ cut: $M_{ee\mu\mu} = M_h \pm 10$ GeV.

The four-lepton cut around “$M_h$” is achieved by hypothesizing a Higgs boson resonance and scanning across that hypothesis. Such a scan is realizable in our case since the signal stands clearly above the continuum background. The signal and background cross-sections are shown in Table II. We find that the 4-lepton invariant mass cut is most effective in reducing the background. The $S/B$ is good for all the benchmark points, but can be improved further by the additional cut: $M_{\ell^+\ell^-} \neq M_Z \pm 10$ GeV, which removes on-shell $Z$-bosons surviving in the data sample.

Conclusions. In our chosen example cases with large mixing among the SM and hidden sector Higgs bosons and light-enough $M_Z'$ for $h \to Z'Z'$ to be on-shell, the prospects for seeing the signal at the LHC are excellent. The signals for the various examples are well above background after all cuts have been applied. The Tevatron is also beginning to achieve the sensitivity required to see the signal; however, there the key challenge is not signal to background, but overall signal rate and luminosity to collect enough events to reconstruct a resonance. Once sufficient luminosity is achieved, and after more tailored techniques are applied to the problem, such as those to search for SM $ZZ$ events [26], the Tevatron should be in a position to probe well a light Higgs boson decaying in the manner proposed here.

[27] A third renormalizable operator involves a SM gauge singlet fermion $N$ with the Yukawa interaction $N LH$ related to neutrino mass generation (note however that $N$ carries lepton number). We will not discuss this further in this work since our discussion here is largely independent of the presence of such an interaction.
