Abstract
Gastric cancer (GC) is one of the most common malignant tumors. The mechanism of how GC develops is vague, and therapies are inefficient. The function of microRNAs (miRNAs) in tumorigenesis has attracted the attention from many scientists. During the development of GC, miRNAs function in the regulation of different phenotypes, such as proliferation, apoptosis, invasion and metastasis, drug sensitivity and resistance, and stem-cell-like properties. MiRNAs were evaluated for use in diagnostic and prognostic predictions and exhibited considerable accuracy. Although many problems exist for the application of therapy, current studies showed the antitumor effects of miRNAs. This paper reviews recent advances in miRNA mechanisms in the development of GC and the potential use of miRNAs in the diagnosis and treatment of GC.

Keywords: Apoptosis; Diagnosis; Drug resistance; MicroRNAs; Neoplasm metastasis; Neoplastic stem cells; Prognosis; Stomach neoplasms; Treatment

Introduction
Gastric cancer (GC) is one of the most common malignant tumors, with high morbidity and mortality worldwide.¹ It produces a tremendous burden, especially in Asia, Latin America, and central and eastern Europe.² GC is second in incidence and mortality of all malignant tumors in China. Approximately 498,000 Chinese people died from GC in 2015.³,⁴ Gastrointestinal endoscopic screening reduces the risk of death in Asian countries.⁵ However, the economic and medical burden for endoscopic screening is too high.⁶ Therefore, it is important and imperative to study and understand the mechanism throughout the development of GC and identify new efficient non-invasive methods for the detection, prognostic prediction, and treatment.

MicroRNAs (miRNAs) are endogenous RNAs, approximately 22 nucleotides (nts), that play regulatory roles in animals and plants. MiRNAs are an abundant class of gene regulators in multi-cellular organisms that may affect the expression of numerous protein-coding genes.⁸,⁹ MiRNAs directly bind to complementary sequences in the 3'-untranslated regions (3'-UTR) of target mRNAs to regulate degradation or translational repression of the target mRNAs. Many miRNAs contribute to cancer development, and the ectopic expression of miRNAs is associated with tumor initiation and progression, such as proliferation, invasion, and other malignant phenotypes.¹⁰,¹¹ During the past decade, studies found that miRNAs were unexpectedly rich in information content with respect to cancer. Analysis of microarray data showed that many miRNAs, long non-coding RNAs (lncRNAs) and circular RNAs (circRNAs) were detected during the process of malignant transformation of GC from normal tissues to atrophic gastritis and tumorigenesis.¹²,¹³ The differential expression pattern of miRNAs in GC creates specific miRNA signatures that characterize distinct histologic subtypes, cancer progression, and patient prognosis.¹⁴,¹⁵ The study of miRNA characteristics and their regulatory genes will help us better understand the functions and mechanism of the development of GC. The present review summarizes the recent advances of the role and application of miRNAs in GC.

Roles of MiRNAs in the Development of Gastric Cancer
MiRNAs are involved in different cellular processes, like metabolism, differentiation, development, and apoptosis.
These miRNAs function as promoters or suppressors depending on the character of the target mRNAs or genes. Specific expression profiles exist in normal and gastric tumor tissues.[17,18] Previous studies showed that miRNAs played a pivotal role in GC progression. MiRNAs function as oncogenes or tumor-suppressive genes to regulate many aspects of GC, such as proliferation, apoptosis, metastasis, chemo-sensitivity and chemo-resistance, and the stemness of cancer stem cells (CSCs) [Figure 1].

**Proliferation**

Several miRNAs may contribute to the proliferation of GC via influencing the growth of cancer cells. Previously, miR-21 was closely related to tumorigenesis. Zhang et al.[19] found that miR-21 was markedly over-expressed in human GC tissues and cancer cell lines, and it repressed reversion-inducing cysteine-rich protein with Kazal motifs (RECK) expression, which resulted in the proliferation and development of GC. Another frequently reported miRNA related to GC cell proliferation is Let-7. The Let-7 miRNA family works as a negative regulator of the target high mobility group AT-hook 2 (HMGA2).[20] Hayashi et al.[21] showed that CagA induced the epigenetic silence of let-7 expression, which triggered the up-regulation of Ras signaling and the proliferation of GC cells. MiR-92b also activated the phosphatidylinositol 3 kinase (PI3K)/protein kinase B (AKT) signaling pathway. Ni et al. found that miR-92b played a supporting role by targeting DOC-2/DAB2 interacting protein in GC cell proliferation.[28] Wang et al.[29] showed that the up-regulation of miR-664a-3p remarkably enhanced the proliferation and invasion via the Hippo pathway in vitro and in vivo. MiR-192 and miR-215 target adenomatous polyposis coli, which is a well-known negative regulator of Wnt signaling function during the tumorigenesis of colorectal cancer to play an oncogenic in GC proliferation and migration.[30] MiR-371a-3p is also a positive force in tumorigenesis via the targeting of transducer of human epidermal growth factor receptor 2 (TOB1).[31] Myeloid-derived suppressor cells, which are marked by the myeloid differentiation factor Slc1a2, showed increased expression of miR-130b, which stimulated epithelial cell proliferation,
promoted the induction of metaplasia, and advanced xenograft tumor growth.\(^{32}\)

Researchers also found that miRNAs acted as tumor suppressive genes in GC. Matsuo et al.\(^{33}\) reported that miR-29c up-regulated regulator of chromosome condensation 2 and suppressed the growth of GC cells, and miR-29c antagonists promoted proliferation. Another study found that miR-29c was lost in the inception phase of gastric tumorigenesis, and further experiments revealed that miR-29c directly targeted integrin β1 to act as a tumor suppressor.\(^{34}\) MiR-203 over-expression and knockdown of its target PIBF1 suppressed tumor cell proliferation, and the knockdown of miR-203 promoted the growth of tumor cells.\(^{35}\) YES proto-oncogene 1 (YES1) activates the Wnt/β-catenin pathway to promote cancer cell proliferation. MiR-140-5p negatively regulates YES1 expression and acts as a tumor suppressor in GC.\(^{36,37}\) MiR-873 and retinoic acid worked in a similar manner to miR-140-5p and YES1.\(^{38}\) H. pylori infection induced interleukin-6 (IL-6) to influence STAT3 activity and suppressed the expression of miR-520d-5p. The inhibition of miR-520d-5p expression promoted cyclophilin B expression and caused activation of STAT3 and the Janus kinase (JAK)/STAT pathway, which resulted in the proliferation of GC cells.\(^{39}\) Min et al.\(^{40}\) demonstrated that miR-30a played a tumor-suppressive role via mediation of integrin subunit α 2 in carcinogenesis. Jiang et al.\(^{41}\) showed that miR-1254 inhibited the PI3K/AKT signaling pathway via the targeting of Smurf1, which led to the suppression of tumor cell proliferation, migration, and invasion.

LncRNA and circRNAs participate in the progression of GC. An increasing number of researchers are paying attention to the interaction between miRNAs and other non-coding RNAs. LncRNA TRPM2-AS acts as a miRNA sponge of miR-612. Silence of TRPM2-AS suppressed GC cell proliferation, metastasis, and radio-resistance, and ectopic expression showed an obvious opposite effect.\(^{42}\) CircRHOBBT3 acted as a sponge for miR-654-3p. Its over-expression produced decreased proliferation, G/S arrest in vitro and xenograft tumor growth inhibition in vivo.\(^{43}\)

### Apoptosis

Anomalous apoptosis is an important reason for cancer occurrence, development, and therapeutic inefficiency. Apoptosis-related genes or miRNAs are novel mechanisms for the study of the development of cancers, and the targeting of these molecules is a potential method for cancer therapeutics.

Zhang et al.\(^{44}\) reported that B-cell lymphoma-2-like protein 11 (BCL2L11) was an important factor mediating apoptosis progress, and miR-24 directly binds to the 3’-UTR of BCL2L11 mRNA to regulate its expression, which enhances GC cell growth and migration and inhibits apoptosis. Duan et al.\(^{45}\) recently found that regenerating gene IV (RegIV) was associated with GC peritoneal metastasis and 5-FU resistance, and it was a target of miR-24. The ectopic expression of miR-24 triggered tumor cell cycle blockade and apoptosis. Except for cancer cell proliferation, miR-17-5p/20a also exerted a pro-apoptotic effect in this experiment. Knockdown of miR-17-5p/20a promoted cancer cell apoptosis and resulted in cell cycle blockade.\(^{46}\) MiR-1265 suppresses cell autophagy and proliferation and increases apoptosis via the regulation of calcium-binding protein 39 expression and the adenosine monophosphate-activated protein kinase-mammalian target of rapamycin signaling pathway.\(^{47}\) Early experiments revealed that poor expression of miR-106b enhanced apoptosis of GC cells via inhibition of the JAK1/STAT3 signaling pathway, and arm protein lost in epithelial cancers on chromosome X 1 was a direct target of miR-106b.\(^{48}\) Low miR-135b expression targeted mammalian sterile 20-like 1 to regulate the mitogen-activated protein kinase signaling pathway, which resulted in apoptosis and inhibition of cisplatin resistance of GC cells.\(^{49}\) MiR-324-3p over-expression contributed to the loss of drosophila protein, mothers against decapentaplegic homolog 4 and activated the Wnt/β-catenin signaling pathway, which resulted in tumor cell growth and apoptosis inhibition. MiR-192a-3p regulated the expression of pituitary homeobox 1, which targeted genes that were all relating to apoptosis, induced apoptosis and suppressed growth in GC cells.\(^{50}\) The above references showed that miRNAs target the main apoptotic genes or affect the signaling transduction to regulate cancer cell apoptosis.

### Invasion and Metastasis

The main reason cancers cause high mortality is because the cells easily invade and metastasize to adjacent tissues or blood vessels. The mechanisms of invasion and metastasis are not clear. Studies of the mechanisms of tumor invasion and metastasis are urgent for early diagnosis. MiRNAs are related to the invasion and metastasis of GC and may be used as a tool for the detection and therapeutic targeting of the metastasis of cancers.

Many recent studies found that miRNAs played a pivotal role in the metastasis of GC cells, which involved many signaling pathways. The Wnt signaling pathway also produced a marked effect.\(^{51}\) Peng et al.\(^{52}\) determined that miR-194 targeted suppressor of fused homolog (SUFU), which is an important negative regulator of Wnt and Hedgehog signaling. The anti-SUFU siRNAs eliminated the suppression of the antagonists and promoted tumor migration and proliferation. MiR-29c-3p mediated an inner ear-specific protein, cell migration inducing hyaluronan binding protein (KIAA1199 or CEMIP), expression and activated the fibroblast growth factor receptor 4/Wnt/β-catenin and EGFR signaling pathways, which induced metastasis behavior.\(^{53}\) Kang et al.\(^{54,55}\) recognized that miR-15a and miR-16-1 acted as tumor suppressors that improved the metastasis and proliferation of GC via the targeting of YES-associated protein 1 and activation of the rapidly accelerates RAF/mitogen-activated protein kinase (MEK)/extracellular signal-regulated kinase (ERK) signaling pathway. Wang et al.\(^{56}\) found that the tumor-suppressive miRNA miR-218 inhibited metastasis via the POU class 2 homeobox 2-oriented network, including simultaneously mediating multiple molecules. The network also regulated the NF-κB and slit guidance ligand 2/ligand of the roundabout 1 signaling pathways and modulated the metastasis of GC cells. The high expression of miR-27a was closely related to the metastatic

1858
characteristic of the patients’ clinical statistics. MiR-27a plays a pro-metastatic effect via inhibition of the PH domain and leucine-rich repeat protein phosphatase 2 and activation of the protein kinase B/glycogen synthase kinase 3 β (AKT/GSK3β) pathway. MiR-939 suppressed the migration and invasion phenotype and decreased the incidence of lung metastasis in vivo via targeting of the solute carrier 34 A2 (SLC34A2) to inhibit the SLC34A2/Raf/MEK/ERK pathway. Many studies clearly indicated the different targets of miRNAs in tumor cells. Wu et al. found that miR-19a/b, Max dimerization protein 1 and c-Myc created a positive feedback loop that facilitated the malignant phenotype metastasis. MiR-589 participated in an atypical miR-589-leukemia inhibitory factor receptor-PI3K/AKT-c-Jun feedback loop as a facilitating factor, which induced tumor cell metastasis and invasion. MiR-647 suppressed GC cell migration via the serum response factor/myosin heavy chain 9 axis. Down-regulation of miR-142-5p directly promoted the expression of the cysteine-rich angiogenic inducer 61 and promoted cell metastasis. The silencing of miR-34a also up-regulated insulin-like growth factor 2 mRNA-binding protein 3 expression and promoted metastasis. Blockade of autophagy-mediated glutaminolysis contributed to GC growth and metastasis, and Zhang et al. found that miR-133a-3p targeted gamma-aminobutyric acid type A receptor-associated protein-like 1 (GABARAPL1) to trigger this process. He et al. found that hypoxia-inducible miR-224 acted as an oncogene to promote the migration and invasion phenotype via targeting and lowering Ras-association domain family 8 (RASSF8) expression. Knockdown of RASSF8 promoted the transcriptional activity of NF-κB and p65 translocation. Mousa et al. showed that miR-4316 inhibited vascular endothelial growth factor A (VEGF-A) expression and induced the suppression of migration and colony formation in tumor cell lines. β-Elemene extracted from Chinese herbal medicine showed a good effect on the inhibition of metastasis in nude mice. Deng et al. confirmed that β-elemene suppressed miR-1323 and up-regulated casitas B lymphoma-b (Cbl-b) expression to achieve these results.

Angiogenesis is critical for the progression of invasion and metastasis. MiR-21 played an important role during tumor angiogenesis via the targeting of RECK and regulation of matrix metalloproteinases. Ye et al. discovered that the low expression of miR-7 activated p65-mediated abnormal NF-κB expression and promoted metastasis, which ultimately led to a poor prognosis. The delivery of miR-7 in BALB/c mice produced therapeutic effects via the inhibition of angiogenesis, lymph node metastases and inflammation. Zhang et al. demonstrated that low miR-29a/c expression promotes the release of VEGF in GC cells, which enhanced vascular cell growth and angiogenesis. Exosomal miR-155 caused tumor angiogenesis via the down-regulation of c-Myc and up-regulation VEGF, but it also suppressed the expression of Forkhead box O3 protein. MiR-23a derived from exosomes promoted tumor angiogenesis via suppression of phosphatase and tensin homolog (PTEN) expression.

Interaction with other non-coding RNAs also affects invasion behavior. LncRNA RGMB-AS1 functioned as a miR-574 sponge and up-regulated histone deacetylase 4 to promote aggressiveness behavior. LncRNA UCA1 is a competing endogenous RNA of miR-495 that up-regulates phosphatase of regenerating liver-3 expression to accelerate the development of GC. MiR-150-5p and its sponge circLMTK2 showed a positive effect on proliferation and metastasis in GC via the regulation of c-Myc expression. The above studies demonstrated the indispensable roles of miRNAs in the process of migration, invasion, and metastasis of GC.

Drug Sensitivity and Drug Resistance

Chemotherapy is the standard therapy for advanced GC. Chemotherapy is useful in the treatment of advanced malignant tumor patients and extends their survival time. However, multi-drug resistance generally leads to treatment failure and a poor prognosis of patients. Drug sensitivity and drug resistance are common in diverse cancer cells, and many factors influence the drug response. Commonly administered chemotherapeutic agents include platinum drugs and 5-fluorouracil. The roles of miRNAs in the modulation of chemo-sensitivity and chemo-resistance have received increased attention.

MiRNAs have the capacity to affect drug sensitivity via specific genes or signaling pathways. Wang et al. found that cisplatin (DDP) and docetaxel (DOC) restored the expression of miR-29 family members. Via suppression of catenin-δ and Ras homolog gene family member A (RhoA) signaling, MiR-29 family members mediate a significant part of the efficacious benefits of patients via suppression of catenin-δ and Ras homolog gene family member A (RhoA) signaling, especially patients who experienced recurrence after chemotherapy. MiR-148a-3p conferred mitochondrial fission and suppressed cyto-protective autophagy by enhancing cisplatin cytotoxicity in experiments. Chen et al. found a decreased concentration of miR-143-3p in gastric tumor tissues, and miR-143-3p transgenic expression in cell lines diminished proliferation and regenerated chemosensitivity to cisplatin via the targeting of bromodomain-containing protein 2. Suppression of miR-633 expression significantly enhanced doxorubicin (DOX)/DDP-induced GC cell apoptosis in vitro by increasing Fas-associated protein with death domain protein levels, and miR-633 antagonists in combination with DOX prominently decreased tumor growth and sensitized tumors cells to chemotherapy. A positive feedback loop played an important role in the chemoresistance to oxaliplatin and metastasis via epithelial-mesenchymal transition (EMT) and stemness-like properties. The over-expression of miR-577 suppressed SDPR expression and released a complex that included serum deprivation protein response protein to activate the ERK-NF-κB pathway, which up-regulated the transcription of miR-577. MiR-508-5p also influenced multi-drug resistance. High expression of miR-508-5p targeted P-glycoprotein and zinc ribbon domain-containing 1 and changed the chemo-resistant phenotype of tumor cells. Shao et al. found that a high level of miR-135b-5p suppressed apoptosis and induced cisplatin resistance. Zheng et al. demonstrated that E2F transcription factor 1 (E2F1) decreased miR-34c expression to promote resistance to paclitaxel combined with cisplatin in GC cells. Liu et al. created nanoparticles (NPs) that were stimulated by gelatinase to co-transport miR-200c and docetaxel, and
the results showed that the released miR-200c had a significantly synergistic effect of docetaxel. Exosome-delivered anti-miRs also have chemo-sensitive and chemo-resistant functions. For example, miR-374a-5p overexpression promoted a chemo-resistance characteristic of GC cells, and miR-374a-5p knockdown had an opposite effect. Exosome-delivered anti-miR-374a-5p promoted cell apoptosis and reversed oxaliplatin resistance via enhancing neurogenic differentiation 1 levels. Wang et al. also reported that exosome-mediated delivery of a miR-214 inhibitor reversed a DDP-resistant phenotype. DDPosomal transfer of the oncogenic miRNA miR-501 inhibited cell death inducer expression, inactivated caspases-9/-3 and induced phosphorylation of AKT, which led to a rapid growth rate of tumors and resistance to DOX.

Chemotherapy with fluorouracil is also widely used in the clinic for GC treatment. Li et al. demonstrated that treatment with 5-fluorouracil increased the expression of miR-204 and inhibited the transforming growth factor-β (TGF-β) pathway, and high miR-204 expression may reverse the chemotherapy resistance via the targeting of TGF-β receptors 1. Zhang et al. found that miR-567 exerted its chemo-sensitive function to 5-fluorouracil and oxaliplatin in tumor cells primarily by a miR-567-PK3AP1-P13K/AKT-c-Myc feedback loop. Another report showed that miR-939 enhanced 5-fluorouracil-induced chemo-sensitivity via inhibition of the SLC34A2/Raf/MEK/ERK pathway, which was activated in research studies. For TNF-related apoptosis-inducing ligand (TRAIL), which is a novel and low-toxic antitumor drug, one study showed that GC miR-494 expression level was associated with a TRAIL-sensitive phenotype. The above research achieved treatments with these miRNAs may be a novel approach to reverse drug resistance. The above research achievements are meaningful in the clinical application of drug-resistant diagnosis and further chemotherapy drug sensitization treatments, especially for advanced patients.

### Stemness of Cancer Stem Cells

CSCs are an important origin for cancer occurrence and recurrence. CSCs are the origin of cancer and targeting CSCs may be of significant clinical value in the treatment of GC. One miRNA may regulate CSCs via various target genes and have an amplifying effect in the regulation of CSC properties.

CD44 is a CSC marker. Mounting evidence shows that the ectopic expression of CD44 also influences the stemness of cancer cells. MiR-34a, a key regulator of tumor suppression, decreases CD44 level. Jang et al. designed nanovesicles containing poly L-lysine-graft-imidazole (PLI)/miR, PLI-condensing miRs, and found that the application of this PLI/miR-34a-containing nanovesicle to nude mice suppressed the expression of CD44. They further found that in CD44-positive tumor-bearing mouse models, this PLI/miR-34a-containing nanovesicle also significantly delayed tumor growth in CD44-positive tumor-bearing mouse models. MiR-200c NPs and miR-200c/DOC NPs also negatively regulated CD44 expression and elevated E-cadherin levels and were further reported to inhibit CSC stemness and reverse EMT. Similarly, Li et al. also found that miR-149 expression was markedly down-regulated in cancer-associated fibroblasts, which promoted stem-like properties and EMT of tumor cells. B-lymphoma Moloney murine leukemia virus insertion region-1 (Bmi-1), another known stem cell marker, regulated stemness phenotype in various CSCs. Wang et al. found that miR-34a regulated stem cell-like properties in GC via the regulation of p53 and PTEN-AKT signaling through the c-Myc/Bmi-1/miR-21 pathway.

MiR-21 was also up-regulated by chromobox protein homolog 7 and maintained the stem cell-like features of GC. MiR-26a targeted homeobox transcription factors C9 (HOXC9) promoted the stemness phenotype and metastasis of tumor cells. Some classic signaling pathways are also regulated by miRNAs. For example, miR-501-5p directly targeted and inhibited several repressors of the Wnt/β-catenin signaling cascade to enhance a stem-cell-like phenotype. In Drosha-silenced or Drosha low-expressing GC cells, miR-6778-3p up-regulated serine hydroxymethyltransferase 1 to mediate a compensatory activation of cytoplasmic carbon metabolism, which was essential for the maintenance of CSCs in GC. IL-1 signaling up-regulated the expression of miR-135b, promoted stem-cell characteristics and the invasiveness of tumor cells via decreasing of RECK and forkhead box N3 (FOXN3) miRNAs. Because CSCs that endow malignant phenotypes to normal cancer cells are regarded as the initiation of cancer, miRNAs in the regulation of CSCs also regulate other malignant phenotypes, such as growth, metastasis, and chemo-resistance, even in precancerous lesions. For example, the miRNA-17-92 cluster includes seven members: miR-17-5p, miR-17-3p, miR-18a, miR-19a, miR-19b, miR-20a, and miR-20b. Wu et al. reported that the over-expression of miR-17-92 cluster members (miR-92a, miR-20a, and miR-19b) maintained the self-renewal ability of gastric CSCs and promoted proliferation of tumor cells, perhaps via the targeting of E2F1 and homeodomain-interacting protein kinase 1 and inhibition of

Roles of MiRNAs in the Clinical Application of Gastric Cancer

Diagnostic prediction

Multiple miRNA expression signatures in tissues may contain many information for GC diagnosis. For example, the differential expression of miRNAs in cancer tissues may be used as a representation of different types of GC. Four miRNAs (miR-138, miR-196a, miR-150, and miR-155) were specifically over-expressed and two miRNAs (miR-7 and miR-153) were decreased in the tissues of gastric mucosa-associated lymphoid tissue (MALT) lymphomas patients. Another study in Japan showed that eight miRNAs (miR-145, miR-133a, miR-125b, miR-99a, miR-105, miR-143, miR-199a, and miR-100) were over-expressed in diffuse-type GC, and four miRNAs (miR-202, miR-494, miR-373, and miR-498) were over-expressed in intestinal-type lesions. Studies also showed the outcome prediction value of miRNA expression signatures. Li et al. identified a seven-miRNA signature in paraffin-embedded GC tissues, the miR-30a-5p, miR-21, miR-126, miR-338, let-7a, miR-10b, and miR-223 expression signature may be used as a predictor for overall survival (hazard ratio [HR] = 3.046) and relapse-free survival (HR = 3.337) of tumor patients.

With the growing number of patients with GC, the lack of non-invasive detection methods for early diagnosis is one of the biggest problems in China. Non-invasive body fluid tests for the detection of cancers are a satisfactory method. However, the present serum tumor biomarkers for GC, such as carcinoembryonic antigen, have a low positive rate. MiRNAs are small and relatively stable in blood, which is easier for testing. Therefore, the detection of circulating tumor-specific miRNAs has become a novel method for the diagnosis and prognosis of tumors. Different miRNAs were found and detected in the blood of patients with carcinoma of the stomach, and some of these markers may be used for further diagnosis and prediction of prognosis. Shin et al. recognized a three-miRNA signature (miR-652, miR-629, and miR-627) as a promising classifier for GC using microarray screening. They tested the signature in patient plasma samples and got a sensitivity of 86.7% and specificity of 85.5%. Huang et al. also identified a six-miRNA panel in serum, and the area under the receiver-operating characteristic curve was 0.702 in the validation phases.

Except for tissue and blood, detecting miRNA expression in other fluids, such as gastric juice and urine, may also be a useful method for diagnosis. MiR-21 and miR-106a levels in gastric juice were obviously different in patients with GC compared to those with benign gastric diseases. The value of the area under the receiver-operating characteristic curve was up to 0.969 and 0.871, respectively. A meta-
analysis revealed that the testing of gastric juice miRNAs was reliable and reproducible and may become a new biologic marker for the screening of gastric carcinoma.\textsuperscript{[128]} MiR-6807-5p and miR-6856-5p expression in urine was higher in patients with GC, their expression levels decreased after curative resection, which supports their use as novel biomarkers for diagnosis.\textsuperscript{[129]}

**Prognostic prediction**

Except for diagnostic prediction, miRNAs also have prognostic evaluation value in GC. For example, the expression of miR-200 family members provided superior predictive power for overall survival compared to single indicators.\textsuperscript{[121]} Ueda et al.\textsuperscript{[130]} verified that low expression of let-7g (HR = 2.600) and miR-433 (HR = 2.100) and high expression of miR-214 (HR = 2.400) were related to poor outcome in patients with GC.\textsuperscript{[14]} The expression of miR-153 in tumor tissues was associated with worse overall survival (HR = 0.253) and disease-free survival (HR = 0.228) in patients with GC. Guo et al.\textsuperscript{[131]} found that high hsa-mir-3923 expression in patients with GC may be an independent prognostic element for poor survival. Chen et al.\textsuperscript{[132]} developed a prognostic model that included six miRNAs (miRNA-549, miRNA-100, miRNA-653, miRNA-374a, miRNA-668, and miRNA-509-3). This miRNA signature differentiated between high- and low-risk patients (HR = 1.699) and forecast 3- and 5-year survival.\textsuperscript{[133]} MiR-1236-3p expression in tumor tissues was significantly declined, which was an independent prognostic factor for overall survival in patients with GC.\textsuperscript{[134]}

MiRNA expression in blood samples may also be used for prognostic prediction. Multivariate analysis showed that low miR-203 levels and high miR-25 levels in serum independently forecast metastasis and poor prognosis for patients with GC.\textsuperscript{[122,134]} Hou et al.\textsuperscript{[135]} confirmed that low serum miRNA-206 expression may be used for diagnosis and to predict the recurrence of gastric carcinoma and patients’ prognosis. Liu et al.\textsuperscript{[136]} found that 7 miRNAs (miR-125b, let-7e, miR-222, miR-148a, miR-21, miR-26a, and miR-126) in plasma predicted the recurrence and prognosis of GC independently or in combination with a pathologic factors index (HR = 1.839 of seven miRNAs and HR = 3.379 of the combination in validation set). Further study showed that patients with stages II and III GC benefited from the prognostic prediction. Nishibeppu et al.\textsuperscript{[137]} reported that high levels of miR-1229-3p in plasma were an independent predictor of poor prognosis for recurrence-free survival in GC (HR = 3.710).

Previously published work provided information on specific miRNA expression, and a ton of data demonstrated that these miRNAs exhibited decent sensitivity and specificity for the diagnosis and prognosis prediction of GC. Although more independent extensive groups or cohorts are needed to verify the conclusions of previous studies, miRNAs may be a group of new, non-invasive biomarkers with ample accuracy for GC diagnostic and prognostic analyses.

**Cancer treatment**

The treatment for GC includes operative and non-operative treatments. Although surgery is conventional for solid tumors, over half of the patients experience a relapse or general metastasis.\textsuperscript{[13]} Therefore, non-operative treatments are indispensable. The clinical use of miRNAs as a treatment for GC remains in the experimental phase in helping to enhance chemo-sensitivity or chemotherapy response. An ongoing clinical trial focused on the discovery and validation of miRNAs in predicting the effect of chemotherapy response in patients with GC. These researchers tried to combine biologic biomarkers and clinical factors to establish a prediction model for promoting the response of chemotherapy in GC (data from [https://clinicaltrials.gov]).

Except for being chemo-sensitive or chemo-resistant, miRNAs may also be used to enhance therapeutic efficacy in cancers. MiRNA-based drugs may have bright application prospects. Some miRNAs are being tested as an miRNA-based cancer therapy in clinical trials. A clinical trial of MRX34 (Mirna Therapeutics, Austin, Texas, USA) constructed a miR-34 mimetic to re-express miR-34 in cancer cells. The experiment was performed in patients with primary liver cancer or liver metastases in a phase I clinical trial protocol.\textsuperscript{[138,139]} In a pre-clinical study for non-small cell lung cancer, MRX34 treatment had marked effects in decreasing the expression of the checkpoint signal PD-L1 and enhancing the expression of CD8(+) cells in cancer tissues.\textsuperscript{[140]} MRX34 showed some curative effect in this experiment, but this clinical trial was stopped in 2016 because of the various and severe immune side effects in patients.\textsuperscript{[141]}

It is obvious that the safety and efficiency of miRNA-based drugs remain a problem. More studies are required to focus on the use of miRNAs in laboratory-to-clinical transformation.

**Prospect**

As one of the most common malignant tumors in China, GC causes a high mortality rate annually. Recent research of miRNAs and cancers has drawn great attention from scientists, and many researchers examined the relationship between miRNAs and GC from laboratory to clinical applications. Numerous miRNAs were found and their functions, properties and signaling pathways were studied. However, it is important to study the interaction networks between miRNAs and investigate whether these molecules work synergistically or counteract each other. Problems still exist. The results of these studies are not consistent, and various miRNAs exhibited conflicting results of expression in different cohorts.\textsuperscript{[11]} The expressions of miRNAs are the characteristic of heterogeneity in different studies, especially circulating miRNAs.\textsuperscript{[142,143]} Even if specific miRNAs correlate with tumorigenesis and have diagnostic or prognostic values, most of the studies were case control studies with small sample sizes. Further investigation with large-scale validation is needed. Problems occurred during clinical transformation, and abundant evidence is needed before miRNAs may be adopted to treat people with cancer. Additionally, there are few large-scale investigations on the safety and efficacy of miRNA-based drugs.

The development of cancer is a multi-gene and multi-step continuous dynamic process, and we still have a long way
to go. Fortunately, recent studies showed the broad prospects of miRNAs. The relatively stable property of miRNAs in the circulation makes them suitable for use as circulating biomarkers in cancer diagnostic and prognostic analysis. Furthermore, the acquisition of a miRNA signature compared to a single miRNA is more likely to provide useful information for clinical use on the individual-based management of diseases. Elucidation of the functions and relationships between these miRNAs and their target genes will increase the prospect for the effective therapeutic method for patients with GC. To achieve this goal, the optimization of laboratory techniques and experiment flow is necessary. Up until the present moment, the effect of miRNA application in the early diagnosis and risk stratification of precancerous lesions of GC is not clear. The application of miRNAs from laboratory to clinical transformation in therapeutics remains a big problem, but these molecules may be a promising research direction.

Conclusions
Abundant research supports that miRNAs provide a novel understanding in the occurrence and development of GC. MiRNAs may function to target miRNAs for regulation and interaction with other non-coding RNAs. The characteristics of miRNAs, like presence in accessible body fluids, make miRNAs promising biomarkers and potential targets for therapeutic interventions. Although converting research of basic medicine to clinical practice remains a huge challenge, experimental results offer hope for further research.

Funding
This work was supported by grants from the National Natural Science Foundation of China (No. 81873554) and the Shaanxi Innovation Foundation of Team of Science and Technology (No. 2018TD-003).
