Describing a novel chemotherapeutic drug formulated by Diosmin for the treatment of acute lymphoblastic leukemia and diabetes mellitus

**Type**
Research paper

**Keywords**
cytotoxicity, molecular modeling, aldose reductase, alpha amylase, Diosmin

**Abstract**

**Introduction**
Diosmin is a natural citrus flavone with remarkable antioxidant and anti-inflammatory features. Acute leukemia is a common type of cancer that is caused in the blood.

**Material and methods**
Alpha amylase activity was determined by a method adapted from the work of Taha et al.

**Results**
In this study, we examined its effect on some important enzymes, the IC50 values were 196.07 for Aldose reductase, and 76.40 for alpha amylase. The molecular docking study was performed to assess the binding affinity and biological activities of diosmin in the presence of alpha amylase and aldose reductase. The results of the docking study indicated that diosmin has a remarkable binding affinity to these enzymes with a docking score of -9.768 and -140469 for alpha-amylase and aldose reductase, respectively. Therefore, this compound could be used as a potential inhibitor for these enzymes. In the cellular and molecular part of the recent study, the treated cells with Diosmin were assessed by MTT assay for 48h about the cytotoxicity and anti-human acute lymphoblastic leukemia properties on HL-60, Clone 15 HL-60, HL-60/MX1, and HL-60/MX2 cell lines. The IC50 of Diosmin were 466, 323, 502, and 537 µg/mL against HL-60, Clone 15 HL-60, HL-60/MX1, and HL-60/MX2 cell lines, respectively.

**Conclusions**
The viability of acute lymphoblastic leukemia cell lines reduced dose-dependently in the presence of Diosmin. It appears that the anti-human acute lymphoblastic leukemia effect of Diosmin is due to their antioxidant effects.
Describing a novel chemotherapeutic drug formulated by Diosmin for the treatment of acute lymphoblastic leukemia and diabetes mellitus

Abstract

Context: Diosmin is a natural citrus flavone with remarkable antioxidant and anti-inflammatory features.

Objective: Acute leukemia is a common type of cancer that is caused in the blood.

Materials & Methods: Alpha amylase activity was determined by a method adapted from the work of Taha et al.

Results: In this study, we examined its effect on some important enzymes, the IC$_{50}$ values were 196.07 for Aldose reductase, and 76.40 for alpha amylase. The molecular docking study was performed to assess the binding affinity and biological activities of diosmin in the presence of alpha amylase and aldose reductase.

Discussion: The results of the docking study indicated that diosmin has a remarkable binding affinity to these enzymes with a docking score of -9.768 and -140469 for alpha-amylase and aldose reductase, respectively. Therefore, this compound could be used as a potential inhibitor for these enzymes. In the cellular and molecular part of the recent study, the treated cells with Diosmin were assessed by MTT assay for 48h about the cytotoxicity and anti-human acute lymphoblastic leukemia properties on HL-60, Clone 15 HL-60, HL-60/MX1, and HL-60/MX2 cell lines. The IC$_{50}$ of Diosmin were 466, 323, 502, and 537 µg/mL against HL-60, Clone 15 HL-60, HL-60/MX1, and HL-60/MX2 cell lines, respectively.

Conclusion: The viability of acute lymphoblastic leukemia cell lines reduced dose-dependently in the presence of Diosmin. It appears that the anti-human acute lymphoblastic leukemia effect of Diosmin is due to their antioxidant effects.

KEYWORDS: Diosmin, cytotoxicity, alpha amylase, aldose reductase, molecular modeling
1. Introduction

Aldose reductase (AR) is a monomeric enzyme, weighing approximately 36 kDa, consisting of 315 amino acid sequences and located in the cell cytosol. Carper et al. (1989) [1] determined the primary structure of aldose reductase enzyme for the first time in rat lens. AR is an enzyme that, in the presence of NADPH cofactor, converts aldehydes originating from free oxygen radicals (ROS) into inactive alcohols as well as reducing glucose to sorbitol [2]. In cells with high AR activity, the depletion of NADPH causes an increase in GSH level, thus increasing oxidative stress [3]. As a result of many studies, it is thought that the aldose reductase enzyme is responsible for the reduction of Dglucose to D-sorbitol in the polyol pathway (Kador 1988) [4] and this reaction is associated with complications of diabetes in hyperglycemia. The three-dimensional structure of AR was revealed by X-ray crystallography analysis. Inhibitors interact with the active site of the AR. Because the active site of the AR enzyme has a flexible structure. AR is a cytosolic enzyme and is distributed in the lens of the eye, retina, kidney, adrenal gland, and reproductive organs [5]. The α-amylase has a very important role in the treatment of diabetes. Inhibition of this enzyme delays glucose secretion and absorption in the small intestine. In this event that takes place in the intestine, the level of hyperglycemia is reduced by delaying carbohydrate digestion by inhibitors of enzymes [6,7].

Molecular docking has recently emerged as a versatile method for the investigation of biological activities of chemical compounds. This method as a theoretical approach could provide a more detailed view of interactions and mechanisms between ligand-enzyme complexes [8]. This method can provide valuable information about the various characteristics of the interactions which have been constructed between chemical compounds and biological materials. The obtained data from
the outcomes of the docking study can give the knowledge that biologists need to understand the mechanisms in which an inhibitor could stop the enzyme activity [9].

Acute leukemia is a common type of cancer that is caused in the blood. In severe situations of the acute leukemia, immunotherapy, chemotherapy, radiation therapy, and surgery are administered for the treatment of acute leukemia [10-13]. The chemotherapeutic drugs have many side effects, so finding a new drug with the efficacy of the chemotherapeutic drugs and without any side effect is very valuable. In this regard, many studies have proven excellent anticancer properties of biotechnology materials such as antioxidant molecules [13].

In the recent study, the properties of prepared Diosmin against acute lymphoblastic leukemia (HL-60, Clone 15 HL-60, HL-60/MX1, and HL-60/MX2) cell lines and diverse enzymes were evaluated.
2. Experimental

2.1. Anti-acute lymphoblastic leukemia properties of Diosmin

The process of the controlled culture of prokaryotic or eukaryotic cells in a filtered or unfiltered flask or cell culture plate by a suitable culture medium is called. This term is mostly used for culturing multicellular cells. Special culture media are used to culture cells. The cells are usually cultured at 37 °C in equipment such as CO₂ incubators. Cell culture should be performed under aseptic (disinfected) conditions because the growth of these cells is much slower than the growth of bacteria and yeasts and there is a possibility of contamination of the culture medium. Antibiotics such as penicillin, streptomycin, or gentamicin are sometimes used to stop the growth of bacteria. In order for cells to proliferate well in culture medium, their density in culture medium must be low. For this purpose, the cells should be passed to the fresh culture medium from time to time. One of the goals of cell culture is to study cells in terms of how they grow, their nutritional needs, and the reasons they stop growing, each of which can have a profound effect on the morphology of the cells we see under a microscope. Therefore, to study the cell growth cycle, develop methods to control the growth of cancer cells and modulate the expression of genes, it is necessary to cultivate these cells in the external environment [14].

With the help of cell culture, cells can be prepared that are in different stages of differentiation and can be differentiated into other cells with the help of hormones and growth factors. With the help of cell culture, homogenous cells can be prepared and intracellular activities such as DNA replication, DNA transcription synthesis, RNA and protein synthesis and other details related to metabolism can be studied. It is also possible to examine the subsequent events and intracellular currents, such as the displacement of these complexes, the type of intracellular messages, and how the messages are transmitted, after connecting different molecules to the corresponding membrane.
The cultured cells can be stored frozen at very low temperatures. Such conditions will maintain the growth rate or genetic composition of these cells and can be thawed and used again at the appropriate time. This prevents the aging of cells, while it is currently not possible to prevent the aging of animals. When working with laboratory animals, systemic changes due to the effect of the animal's natural homeostasis or the stress of the experiments on the results should be considered. While the use of cell culture eliminates this problem. In addition, standardizing laboratory tests is easier and more practical than tests on living organisms. In laboratory environments, it is much easier to control the physical and chemical factors in the living environment of cells, including acidity, heat, osmotic pressure, and the pressure of gases such as oxygen and carbon dioxide. Cells that are taken directly from the individual are known as primer cells and have a limited lifespan. Most cells have a limited lifespan, except for those taken from a tumor. An immortal cell line can proliferate indefinitely by creating a random or targeted mutation (such as artificial expression of the genus and be established as a representative of specific cell types [14].

In this research, we used the following cell lines to evaluating anti-acute lymphoblastic leukemia and cytotoxicity effects of Diosmin using an MTT method.

a) Normal cell line:
- HUVEC.

b) Human acute lymphoblastic leukemia cell lines:
- HL-60, Clone 15 HL-60, HL-60/MX1, and HL-60/MX2.
In the recent study, the cells were cultured in medium (RPMI1640 = Roswell Park Memory Institute1640) with 10% FBS combined with penicillin and streptomycin antibiotics in an incubator containing 5% CO₂ in a flask (T25). After three passages for purification, the cells were used to perform the next steps. Cell count and the number of viable cells were performed with a hemocytometer slide using trypan blue. Evaluation of the cytotoxic effect of the Diosmin was performed by the modified 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-2H-tetrazolium bromide (MTT) colorimetric test. In this method, MTT, which is yellow, is converted to insoluble and formazan purple dye by the dehydrogenase enzymes in the mitochondria of active cells. The adsorption of this compound can be measured after dissolving at 570-540 nm. After two days and covering the flask bottom with cell, the cell layer adhering to the flask bottom was isolated enzymatically using trypsin-EDTA (5%) (Tetraacetic acid ethylenediamine), after transfer to sterile test tubes, it was centrifuged at 2000 rpm for 10 minutes. The cells were then resuspended in a fresh culture medium with the help of a pasteur pipette and cell suspension (10⁶ ml/μg) was prepared from them. 40 μl of this cell suspension (equivalent to 10⁴×4 cells) was poured into 96-well plate flat-bottomed wells (for cell culture). Then the final volume of each well with 10% FBS medium reached 200 μl. The first-row containing cell suspension was considered as negative control (control). After incubation for 18-24 hours to remove cells from the stress caused by trypsinization, the supernatant was removed slowly and carefully, A new medium was added to all rows with different concentrations of the Diosmin (only a new medium was added to the negative and positive control rows), so that the diluted Diosmin with concentrations of 1-1000 μg/ml was added to the third to sixth rows, respectively, the plate was incubated in CO2 for 48, 24 and 72 hours. After the incubation time, the plate was taken out of the incubator and 20 μl of MTT (Sigma) was added to all wells, and incubated for 3 hours. The supernatant was then gently removed and
100μl of DMSO was added to the wells and pipetted to dissolve the formazan crystals. The amount of light absorption (OD) according to the intensity of the blue color of formazan at 540 nm was read by Eliza reader. To convert OD to the percentage of living cells, the following formula was used and the percentage of cell life at each concentration was calculated after 48, 24 and 72 hours [14].

\[
\text{Cell viability (\%) } = \frac{\text{Sample A.}}{\text{Control A.}} \times 100
\]

The concentration of the tested compounds that reduced the percentage of cell life by half was considered as IC50 (The half maximal inhibitory concentration) [14].

2.2. Qualitative Measurement

At least three independent replications were performed for each data and the result was presented as mean ± SD. Data statistical analysis was done with SPSS software version 22 and Anova Way One and Duncan tests. Significance was considered at the level of \(P\leq0.05\).

2.3. Enzymes methods

Alpha amylase activity was determined by a method adapted from the work of Taha et al. [15] accordingly, α-amylase solution, phosphate buffer and starch from the reaction components were incubated in an eppendorf tube at 35 °C for 10 minutes. 100 μL of dinitrosalicylic acid (DNS) was added to the reaction and the reaction mixture was boiled for 5 minutes to stop the reaction. The reaction mixtures cooled to room temperature were diluted with 1000 μL of distilled water and
Absorbance measurements were performed at 540 nm [16]. One unit of enzyme activity was calculated as the amount of 1 μmol maltose released in 1 minute under the reaction conditions. For AR, these solutions were used: 1 M Na-phosphate buffer, pH=5.5, 0.11 mM NADPH solution, and 4.7 mM DL-glyceraldehyde solution. The activity measurement of the AR enzyme was performed by modifying the procedure used by Cerelli et al. (1986) [17]. The reaction medium was prepared by adding 50 μl of isolated enzyme to 250 μL of Na-phosphate buffer, 100 μl of NADPH and 500 μl of distilled water. The reaction was initiated by adding 100 μl of DL-glyceraldehyde to the cuvette prepared above. The decrease in NADPH concentration at 340 nm and room temperature was followed by a spectrophotometer for 3 minutes. Then, intervals with linear absorbance values were determined and slope calculations were made. For the IC₅₀ study, we obtained different activities using different inhibitor concentrations and calculated the percent activities and obtained them in graph form. We repeated 3 times them [18].

2.4. Molecular docking study

Molecular docking study as a versatile theoretical approach was used to evaluate the biological activities of diosmin as an inhibitor for alpha-amylase and aldose reductase numerically. For this purpose, the structures of human pancreatic alpha amylase (PDB ID: 1HNY) [19] and human aldose reductase (PDB ID: 1US0) [20] were downloaded from the PDB database (http://www.rcsb.org/pdb). The unprocessed structure is not ready to be used for docking study. Therefore, some preparation process has to be done. Some of the main steps are the addition of hydrogen atoms to the structure, water molecule removal, creation of H-bond network, and minimization of the system. The minimization step was carried out using the OPLS3e force field.
All of the preparation processes were accomplished using the preparation module of the Schrödinger Suite [21]. The structure of diosmin was obtained from the Pubchem database in SDF format, and the correct molecular geometries were produced using the LigPrep module of Schrödinger [22]. The suitable protonation states were also produced using the Epik module. The binding sites of the enzyme structure were predicted, and their related scores were determined using SiteMap of Schrödinger [23]. A grid of (20×20×20 Å³) was created around the first predicted active site. Finally, Glide of Schrödinger suites was utilized to perform molecular docking investigations.

3. Results and Discussion

3.1. Cytotoxicity and anti-acute lymphoblastic leukemia activities of Diosmin

Cancer is recognized as one of the leading causes of death in today's society and several drugs have been introduced to treat this disease, but, most common cancers are not yet controllable and this disease imposes huge costs on the patient and society. The main factor in the development and progression of cancer has not yet been precisely identified, however, the available data suggest that metabolic disorders in the tissue and immune disorders may be involved in the development and exacerbation of this disease [24-26]. In addition, metabolic disorders in the production and excretion of oxygen free radicals are important factors affecting cancer cells. Free radicals are destructive compounds that are produced as a by-product by the body's chemical reactions and are destroyed by the body's defense system and enzyme system and antioxidants. However, in cases where the body's metabolic disorders and the production of free radicals are high and they are not destroyed by the neutralizing system, due to their instability, these compounds have a strong
tendency to react with a variety of molecules in the body [26-29]. It is estimated that each cell in the human body is exposed to free radicals 10,000 times a day and DNA strands 5,000 times a day. Damage to cell components includes proteins (genetic disorder), fats (lipid oxidation), and cell membranes (permeability disorder) that if the damage is not repaired, it leads to disruption of the chemical reaction and normal proteinization of the cell and the formation of harmful compounds and sometimes cancer cells in the body [25,27]. It is reported that thousands of cancer cells are produced daily in the human body that are killed by the body's defense system. In some cases, due to dysfunction of the above systems, cancer cells proliferate and conditions for cancer development in different tissues. According to the above, antioxidants play a vital role in preventing disorders caused by the effects of free radicals and thus the prevention and treatment of cancer. Antioxidants are a wide range of molecular compounds with complex properties that combine with and neutralize free radicals. The results show that more than 60,000 types of molecular antioxidants have been identified so far. Antioxidants can be effective in three known ways to prevent and treat cancer; 1. Destruction of free radicals 2. Strengthen the immune system to destroy cancer cells. Prevent the adhesion of cancer cells to other cells and prevent their proliferation [24-29].

In this experiment, the treated cells with different concentrations of the present Diosmin were assessed by MTT assay for 48h about the cytotoxicity properties on normal (HUVEC) and acute lymphoblastic leukemia cell lines i.e. HL-60, Clone 15 HL-60, HL-60/MX1, and HL-60/MX2.

The viability of acute lymphoblastic leukemia cell lines reduced dose-dependently in the presence of Diosmin. The IC<sub>50</sub> of Diosmin were 466, 323, 502, and 537 μg/mL against HL-60, Clone 15 HL-60, HL-60/MX1, and HL-60/MX2 cell lines, respectively (Figures 1-3). The absorbance rate was evaluated at 570 nm, which represented viability on normal cell line (HUVEC) even up to 1000μg/mL for Diosmin (Figure 3).
**Fig. 1.** The anti-acute lymphoblastic leukemia properties (Cell viability (%)) of Diosmin (Concentrations of 0-1000 µg/mL) against acute lymphoblastic leukemia (HL-60, and Clone 15 HL-60) cell lines.

- **HL-60**
  - IC50 = 466

- **Clone 15 HL-60**
  - IC50 = 323
Fig. 2. The anti-acute lymphoblastic leukemia properties (Cell viability (%)) of Diosmin (Concentrations of 0-1000 µg/mL) against acute lymphoblastic leukemia (HL-60/MX1 and HL-60/MX2) cell lines.
It seems that the anti-acute lymphoblastic leukemia effect of recent molecule is due to their antioxidant effects. Because tumor progression is so closely linked to inflammation and oxidative stress, a compound with anti-inflammatory or antioxidant properties can be an anticarcinogenic agent [30]. Many molecules have pharmacological and biochemical properties, including antioxidant and anti-inflammatory properties, which appear to be involved in anticarcinogenic and
antimutagenic activities [31]. Today, molecules synthesized by biological methods play a vital role in treating many diseases, including cancer [32]. Molecules synthesized by biological methods are no longer the only ones in traditional medicine, in addition, they have been able to adopt an industrial line of natural products for treating various cancers. Various cell lines from cancers of the prostate, ovary, lung, liver, and pancreas have been treated with herbal molecules synthesized [33].

**Enzymes results**

Naturel compounds containing benzene rings are generally known as "phenolic compounds". Hydroxybenzene, known as 'phenol', in other words, benzene carrying one hydroxyl group, is the simplest form of phenolic compounds [34]. All other phenolic compounds are derived from hydroxybenzene. In this study, the effect of Diosmin as natural compound on AR and alpha amylase was investigated. Indeed, we examined its effect on some important enzymes, the IC$_{50}$ values were 196.07 for Aldose reductase, and 76.40 for alpha amylase. Glucosidase inhibitors are highly promising in the treatment of various diseases such as diabetes, viral infections and cancer metastasis, as well as being a very effective tool for understanding the mechanism of action of glucosidases [35]. Therefore, α-amylase has been the target enzyme for the design of drug molecules suitable for the treatment of diabetes, obesity, and hyperglycemia. In general, it is known that commercially available antidiabetic drugs are α-amylase inhibitors because they reduce postprandial hyperglycemia [36]. Liminoids purified from *Azadirachta indica* for pancreatic alpha amylase inhibition have also been reported to be used as antidiabetic drugs because of their potential therapeutic effects. In addition, it has been stated that tetracyclic diterpenoid (also known as isosteviol) triazole derivatives obtained by acid hydrolysis of stevio
glycoside extract, which is abundant in *Stevia rebaudiana*, are used as antitumor agents in cancer treatment [37]. Aldose reductase inhibitors are used in nephropathy and retinopathy. It produces sorbitol via the glucose aldose reductase enzyme. Ocular retinopathy occurs as a result of accumulation of sorbitol. Aldose reductase enzyme inhibitors (sorbinil, tolrestat, ponalrestat, epalrestat, flavonoid) may also be effective in the treatment of diabetic glomerulosclerosis (hardening of the kidney capillaries) [38].

**Molecular modeling results**

A molecular docking study was conducted for the investigation of biological and chemical activities of diosmin against two enzymes, human pancreatic alpha amylase, and human aldose reductase. The docking pose of the compound in the presence of alpha-amylase is presented in Fig. 4, and the interactions created by diosmin between this ligand and the enzyme are shown in Fig. 5. The results show that the number of hydrogen bonds between diosmin and alpha-amylase is seven bonds which have caused a strong binding affinity with a docking score of -9.768 (Table 1). Asp197 is a very active residue among the enzyme structure, as it has created three hydrogen bonds with diosmin. These hydrogen bonds are very crucial since Asp197 is one of the essential members of the catalytic domain of alpha amylase [39]. Glu233 is another residue that has created a hydrogen bond with diosmin, and like Asp197, this residue is one of the catalytic residues of alpha-amylase [39]. These essential hydrogen bonds show that diosmin is able to inhibit enzyme activity considerably. The other residues with hydrogen bond interaction are Thr1 and 63Arg195.

As could be seen in Fig. 5, twelve other residues have created hydrophobic contacts with the ligand. Asp300 is one of these residues, and since this residue is a catalytic residue [39], this hydrophobic contact is an important interaction. Fig. 6 presents the docking pose of the diosmin against aldose reductase, and the characteristics of their interactions are shown in Fig. 7. As it is
apparent, there are three hydrogen bonds between diosmin and the residues of aldose reductase. The residues that have created hydrogen bonds are Lys21, Gln49, and Asp160. There are a large number of hydrophobic interactions between various residues of aldose reductase and diosmin. Tyr48 and His110 are among twelve residues with hydrophobic contacts. These two residues are the catalytic residues of the enzyme [40], [41], which means that these two hydrophobic contacts are crucial interactions for the inhibitory activity of diosmin. The parameters obtained from docking calculations are shown in Table 1. One of the most essential parameters among the calculated parameters is the docking score [42]. This value for alpha amylase and aldose reductase is -9.768 and -14.469, respectively, which show a remarkable binding affinity of diosmin for these two enzymes. Another parameter is the Glide Ligand Efficiency, which is the parameter to show the energy between molecules and their related binding partner. The Van der Waals energy is shown with Glide Evdw, and Glide Ecol indicates the Coulomb energy. The Glide energy is the numerically calculated energy of the interaction, and the Glide Emodel is the interaction pose value [43]. These results indicate that diosmin has the potential for being used as an inhibitor for both alpha-amylase and aldose reductase. The lower amount of IC50 for alpha amylase could be probably attributed to the number of hydrogen bonds that have been created by diosmin. This number is seven for alpha amylase and four for aldose reductase.

Table 1. The parameters obtained from the molecular docking calculations.

|                      | Alpha amylase | Aldose reductase |
|----------------------|---------------|------------------|
| **IC$_{50}$ (mM)**   | 76.40         | 196.07           |
| **Docking score (kcal/mol)** | -9.768         | -14.469          |
| **Glide ligand efficiency (kcal/mol)** | -0.227         | -0.336           |
| **Glide E Coul (kcal/mol)** | -24.252       | -15.013          |
| **Glide Evdw (kcal/mol)** | -39.650       | -44.165          |
| **Glide Emodel (kcal/mol)** | -91.484       | -82.645          |
| **Glide energy (kcal/mol)** | -63.903       | -59.178          |
4. Conclusion

We determined the antidiabetic properties of the compound we used in the study. Molecular docking could provide valuable information about the interactions, mechanisms, and biological activities of a chemical compound in the presence of biological material such as enzymes. The outcomes of docking calculations revealed that diosmin has a remarkable binding affinity to alpha amylase and aldose reductase, which means this compound is a potential inhibitor for these enzymes. These inhibitory activities could be related to a large number of hydrogen bonds and hydrophobic contacts, which could be created by diosmin. The viability of acute lymphoblastic leukemia cell lines reduced dose-dependently in the presence of Diosmin. The IC$_{50}$ of Diosmin were 466, 323, 502, and 537 µg/mL against HL-60, Clone 15 HL-60, HL-60/MX1, and HL-60/MX2 cell lines, respectively.
