Glucometers for Patients with Type 2 Diabetes Mellitus: Are they helpful?

Andrew Thomas,1 Mohan T Shenoy,2 K.T. Shenoy,1 Nirmal George.1

Abstract

Background: The effectiveness of self-monitoring of blood glucose (SMBG) in type 2 diabetes mellitus (T2DM) patients is debated in the literature. We aimed at elucidating the association and patterns of complications between SMBG use and plasma glucose values. Methods: This cross-sectional study comprised 303 participants from outpatient departments with T2DM for over 12 months. We analyzed sociodemographic and clinical variables including: anthropometry, SMBG use, disease duration, treatment modulation, complications, plasma glucose level, and glycated hemoglobin level (%). Results: The mean duration of T2DM was 93 ± 76 months. Participants were grouped into SMBG users (n=115, 38%) and non-SMBG users (n=188, 62%). The mean fasting plasma glucose levels of SMBG and non-SMBG users were 140.7±42.7 (95% Confidence Interval [95%CI]: 132.7-148.67) mg/dl and 145.4±50 (95%CI: 138.1-152.67) mg/dl (p=0.03), respectively. The mean post-prandial plasma glucose levels of the SMBG and non-SMBG groups were 202 ± 63.42 (95%CI: 190.3-213.76) mg/dl and 209±84.54 (95%CI: 196.5-221.43) mg/dl (p=0.002), respectively. The mean difference in HbA1c among the groups were 10.2±3.6% (95%CI: 7.5-9.88) and 12.05±4.8% (95%CI: 7.7-12.09) (p<0.05), respectively. Hypoglycemia (n=50, 43.5%) was the most common complication. The prevalence of neuropathy (n=5, 4.3%, p=0.036) and cardiovascular disease (n=21, 18.3%, p=0.042) were significantly higher in the SMBG group. Conclusion: Although plasma glucose values were significantly lower in the SMBG group, its clinical significance remains questionable. Furthermore, many participants in both groups had shortfalls in awareness, monitoring, and glycemic control. SMBG use needs to be evaluated in a cohort of patients with T2DM with adequate health awareness.

Key Words: Blood Glucose Self-Monitoring; Type 2 Diabetes Mellitus; Glycemic Control; Blood glucose; Diabetes Complications (Source: MeSH-NLM).

Introduction

India is a country with a high incidence of diabetes mellitus. The morbidity and mortality related to this disease are enormous and pose a significant burden on the public health of this country in the future.1 Venous plasma and capillary whole blood methods are two ways of estimating blood glucose level. The venous plasma glucose level is slightly higher in random and fasting glucose estimation, but lower than capillary whole blood glucose level for samples taken 2 hours after glucose is given orally. However, the diagnostic criteria are similar between these two methods of estimation.2 According to the American Diabetes Association (ADA), random blood glucose values of 79–140 mg/dl are considered normal; 140–200 mg/dl, pre-diabetes; and a value above 200 mg/dl, diabetes. In terms of glycated hemoglobin levels, values less than 6.5% are normal, whereas values between 5.7% and 6.7% are considered high risk.3,4 Control of blood glucose is important in preventing diabetes-associated complications; however, over 70% of all patients diagnosed with diabetes have uncontrolled diabetes.5

Some may argue that self-monitoring of blood glucose (SMBG) can be recommended for all patients with type 2 diabetes mellitus (T2DM).6 This is because SMBG can be useful in detecting hypoglycemia and hyperglycemia. Furthermore, high blood glucose levels encourage patients to improve their diet and physical activity. Multiple SMBG measurements taken over a period of time may also be helpful for physicians to monitor their patients and modify their treatment if needed.6,7 Glycemic variability is a term used to describe the fluctuations of glucose levels. While SMBG may provide diurnal glucose profile, continuous glucose monitoring (CCM) is considered helpful in detecting glycemic variability.8 The data on SMBG practice among patients with T2DM are not well understood. Many studies have been conducted to estimate the effectiveness of SMBG practice, especially among non-insulin-treated patients. Some studies revealed no association between SMBG and glycemic control, whereas others indicated the benefits of SMBG use.9–14 A reduction in hemoglobin A1C (HbA1C) of 0.5% was found when the patients were better educated to interpret the values of SMBG.9 Physicians need to monitor patients with T2DM regularly, because the effectiveness of SMBG is dependent both on patients and appropriate glucometer use.15 Patients should be made aware that practicing SMBG alone will not improve their glycemic control. Good glycemic control is attained only when data obtained are properly interpreted to modify treatment strategies. This study aimed at elucidating the use of SMBG in patients with T2DM by comparing glycemic levels and complication rates among SMBG and non-SMBG users.

Methods

This was a cross-sectional study conducted from May to June 2019. The project was approved by the Institutional Ethical Committee of Sree Gokulam Medical College and Research Foundation (SGMCMRC No.: 34/450/05/2019). Each participant provided a written informed consent before the commencement of the study.

Sree Gokulam Medical College and Research Foundation (SGMC&RF) is a tertiary health center located at Thrivunanthapuram in the state of Kerala, India. Study participants were selected by convenient sampling from the outpatient departments of General medicine, General Surgery, Orthopedics, Endocrinology, Diabetology, and Gastroenterology of SGMC&RF. Participants with T2DM for over 12 months and those aged at least 18 years were included in the study. Pregnant women were excluded from the study.

Socio-demographics, anthropometry (height in cm and weight in Kg), duration of disease (in months), current treatment pattern (6 treatment modalities, namely insulin preparations, oral hypoglycemic drugs except metformin monotherapy, metformin monotherapy, alternative drug therapy like Ayurveda or Homeopathy, combination therapy (insulin and oral hypoglycemic drugs), and no treatment), recent plasma glucose values (fasting, post-prandial in mg/dl, and HbA1C as a percentage), co-morbidities, such as hypertension, dyslipidemia, hypoa-and hyperthyroidism, bronchial asthma, cardiovascular disease (cardiac failure, arrhythmias, and myocardial infarction), stroke (both ischemic and hemorrhagic), neuropathy, nephropathy, and retinopathy, and pattern of SMBG use (duration, frequency) were the variables studied.

Awareness and practice of SMBG among the study participants were enquired and noted. Following data collection, all participants were educated on disease progression and appropriate SMBG practice.

Data were collected through interviews lasting 15 minutes conducted by the principal investigator, using questionnaires on SMBG practice. Height and weight were measured for calculating BMI. Laboratory records, such as blood glucose, lipid profile, and HbA1C, were perused by the principal investigator, using questionnaires on SMBG practice. The sample size was estimated based on a previous report using the Open-Epi (Open-Source Epidemiologic Statistics for Public Health) software. A proportion of 52.4% was assumed to be SMBG users with a precision of 5%, alpha error (0.05), and power of 90%; the required sample size was calculated. All quantitative variables were compared using the mean and standard deviation.

The association between SMBG practice and plasma glucose values was assessed using the independent t-test. Chi-square test and odds ratio were used to determine the association between SMBG use and glycemic values. Sensitivity analysis was not performed.

**Results**

**SMBG Practice**

The study participants were classified into SMBG (115, 38%) and non-SMBG groups (188, 62%). Among the SMBG group, 96 (83.5%), 8 (7%), 5 (4.3%), 4 (3.5%), and 2 (1.7%) participants practiced SMBG irregularly, once weekly, once monthly, once daily, and multiple times a day, respectively.

A summary of different treatment modalities administered to the study participants is given in **Table 1**. Metformin monotherapy administered to 113 (37.3%) participants was the most common treatment modality, whereas 51 (16.8%) and 63 (20.8%) participants were on insulin monotherapy and combined therapy with insulin and oral hypoglycemic drugs, respectively. Participants were grouped based on insulin use for sub-group analysis. No significant difference was observed between them.

**Table 1. Participants Classified According Asian BMI Criteria**

| Asian BMI criteria | SMBG group (n=115) | Non-SMBG group (n=188) | p-value |
|--------------------|--------------------|------------------------|---------|
| Underweight (<18.5 kg/m²) | 7 (6.1%) | 0 | 0.65 |
| Normal (18.5-23 kg/m²) | 44 (37.8%) | 32 (17.2%) | 0.002 |
| Overweight (23.1-27.5 kg/m²) | 37 (32.2%) | 27 (14.4%) | 0.86 |
| Obese (≥27.5 kg/m²) | 92 (80.5%) | 55 (29.2%) | 0.93 |

**SMGB Use and Glycemic Levels**

The mean plasma glucose and HbA1C levels of the SMBG and non-SMBG groups were compared using t-test (**Figure 1**). The fasting plasma glucose levels of 297 participants were analyzed. Among them, 113 participants practiced SMBG. The mean plasma fasting glucose levels were 140.47±42.7 (95%CI: 132.72-148.67) mg/dl and 145.4±50 (95%CI: 138.12-152.67).

Most of the participants (79, 68.7%) performed SMBG after overnight fasting, whereas 3 (2.6%) and 33 (28.7%) participants performed it 2 hours after eating and randomly, respectively. More than half (74, 64.5%) of the participants felt they were not adequately educated about SMBG use. Among the SMBG users, only 38 (33%) participants modified their treatment using SMBG values. The other 78 (67.8%) participants began exercising and had diet modifications because of SMBG use.

In all, 60 (52.2%) participants said they would verify the SMBG values by performing follow-up tests in certified laboratories. However, 48 (41.7%) participants did not perform SMBG values at any time. Following data collection, all participants were enquired and noted. Following data collection, all participants were enquired and noted.
Figure 1. Association between glycemic levels and SMBG use. (A) Mean fasting and Post-prandial plasma glucose between SMBG and Non-SMBG groups. (B) Mean HbA1c between SMBG and Non-SMBG groups. (*) denotes significant difference (p value less than 0.05).

Table 3. Frequency of complications and co-morbidities observed in study participants

| Complications and Co-morbidities | Total (n=303) | SMBG group (n=115) | Non-SMBG group (n=188) | P value |
|----------------------------------|--------------|---------------------|------------------------|---------|
| Retinopathy                      | 54 (17.8%)   | 25 (21.7%)          | 29 (15.4%)             | 0.16    |
| Nephropathy                      | 10 (3.3%)    | 5 (4.3%)            | 5 (2.7%)               | 0.42    |
| Neuropathy                       | 20 (6.6%)    | 12 (10.4%)          | 8 (4.3%)               | 0.04    |
| Hypoglycemia                     | 117 (38.6%)  | 50 (43.5%)          | 67 (35.6%)             | 0.17    |
| Cardiovascular disease           | 40 (13.2%)   | 21 (18.3%)          | 19 (10.1%)             | 0.04    |
| Stroke                           | 8 (2.6%)     | 4 (3.5%)            | 4 (2.1%)               | 0.48    |
| Hypertension                     | 151 (49.8%)  | 49 (42.6%)          | 102 (54.3%)            | 0.04    |
| Dyslipidemia                     | 141 (46.5%)  | 51 (44.3%)          | 90 (47.9%)             | 0.55    |
| Thyroid dysfunction              | 45 (14.9%)   | 15 (13%)            | 30 (16%)               | 0.49    |

More participants who practiced SMBG had neuropathy (n=12, 10.4%, p=0.03) and cardiovascular disease (n=21, 18.3%, p=0.04). The odds ratios (OR) of micro-vascular (OR=1.8, 95% CI=1.00-3.2) and macro-vascular complications (OR=2.1, 95% CI=1.1-3.9) were significantly different when analyzing SMBG and non-SMBG groups, as summarized in Figure 2.

Discussion

The usefulness of SMBG practice among patients with T2DM, especially those without insulin medication, is doubtful in the literature. We conducted a cross-sectional study among 303 patients with T2DM patients with and without SMBG practice, and compared their fasting, post-prandial and HbA1c values. The mean HbA1c values did not differ between the two groups. While the mean plasma glucose values between the groups may be statistically significant, the differences were too infinitesimal to produce a clinically significant difference. A mere 7 mg/dl difference in post-prandial glucose is doubtful to elicit a clinically significant difference in practice.18

One of the specific goals for practicing SMBG is to detect and prevent hypoglycemia.20 Contrary to this, hypoglycemia was the most common complication observed in the participants. Furthermore, no statistically significant difference existed in the proportion of hypoglycemia between SMBG and non-SMBG groups, as reported in literature.21
Most of the complications, except neuropathy and cardiovascular disease, had no statistically significant differences between the two groups. The leading cause of mortality and morbidity in patients with diabetes is related to cardiovascular events. A weak, yet significant association between SMBG use and cardiovascular disease has been reported. Huang et al. observed that frequent SMBG monitoring decreased micro-vascular complications. One interesting finding was that neuropathy and cardiovascular diseases were more prevalent in the SMBG group with statistical significance. Overall, our study observed that more micro-vascular complications were present in the non-SMBG group (29 vs. 30), whereas more macro-vascular complications were present in the SMBG group (24 vs. 21). However, these complications may not be associated with SMBG use. A possible explanation for this finding might be that participants with more complications used SMBG because of severe disease.

SMBG use in T2DM is debated in the literature. Improvement in glycemic control can only be found if the patient is educated about the appropriate ways of practicing SMBG. Many patients in our study were not satisfied with the health education they received from the healthcare provider. Most patients practiced SMBG irregularly and did not confirm or consult physicians on results. This might be the reason for poor response to SMBG practice in our study setting. Perhaps, the most concerning finding in our study was that mean fasting, post-prandial, and HbA1c of both groups were significantly higher than the recommended glycemic targets by American Diabetes Association (ADA), American College of Endocrinologists, and International Diabetes Federation (IDF). In India, education on diabetes is not enough to impart adequate awareness and monitoring status of glycemic control. Thus, determining the efficiency of SMBG is challenging.

The effectiveness of SMBG especially among patients with T2DM who are not on insulin therapy is debated in the literature. A systematic review and meta-analysis conducted in 2012 included 12 randomized controlled trials. They concluded that the effect of SMBG lasted only about six months in these patients. Furthermore, they also observed that the effectiveness decreases after one year. Another multicenter analysis on 24,500 patients from 191 centers observed that patients with T2DM on oral hypoglycemic agents or nutrition therapy derived no apparent benefits from SMBG. These findings are similar to those of our study. One prospective study conducted among 689 patients observed benefits in patients who performed SMBG, but observed a 0.3% reduction in HbA1c level (8.1 ± 1.6% vs. 8.4 ± 1.4%, p = 0.012). Thus, any claims of significant clinical effects of SMBG among SMBG users are doubtful.

The study had few limitations. First, information bias due to reliance on self-declared information was most likely. Second, ideally, a randomized controlled trial would be better to ascertain the differences between the SMBG and non-SMBG groups. Third, while we only included participants who practiced SMBG for at least 6 months, we did not analyze the duration of SMBG use with their glycemic values. Even though our study indicated a significant difference in fasting and post-prandial plasma glucose, participants had shortfalls in awareness, practice, and control of diabetes. Further studies using randomized controlled trials and meta-analysis should be conducted on patients with T2DM using SMBG to determine its effectiveness and establish standard guidelines for SMBG practice.
