References 26

In this exposition, we continue the discussions of Dong [D2] and Li [L]. We shall prove an $S_3$-symmetry of the Jacobi identity, construct the contragredient module for a module for a vertex operator algebra and apply these to the construction of the vertex operator map for the moonshine module. We shall introduce the notions of intertwining operator, fusion rule and Verlinde algebra. We shall also describe briefly the geometric interpretation of vertex operator algebras. We end the exposition with an explanation of the role of vertex operator algebras in conformal field theories.

I would like to thank Masahiko Miyamoto for inviting me to this successful conference and James Lepowsky for helpful mathematical comments.

Notations:

$\mathbb{C}$: the (structured set of) complex numbers.
$\mathbb{C}^\times$: the nonzero complex numbers.
$\mathbb{R}$: the real numbers.
$\mathbb{Z}$: the integers.
$\mathbb{Z}_+:$ the positive integers.
$\mathbb{N}$: the nonnegative integers.

1. $S_3$-symmetry of the Jacobi identity and contragredient modules

The results and constructions discussed in this section are all natural from the axiomatic viewpoint. But they also have practical uses in some very concrete problems. Before going into the detailed discussions, let us first recall one of those problems.

One of the most important examples of vertex operator algebra is the moonshine module constructed by Frenkel, Lepowsky and Meurman [FLM1] [FLM2]. (See the introduction of [FLM2] for a historical discussion, including the important role of Borcherds’ announcement [B].) The construction can be briefly described as follows: From the Leech lattice $\Lambda$, one can construct an untwisted vertex operator algebra $V_\Lambda$. The automorphism $\theta : \Lambda \to \Lambda$ defined by $\theta(x) = -x$ for any $x \in \Lambda$ induces an automorphism of $V_\Lambda$ which is still denoted $\theta$. One can construct a unique irreducible $\theta$-twisted module $V_\Lambda^T$ for $V_\Lambda$. The automorphism $\theta : \Lambda \to \Lambda$ also induces an automorphism of $V_\Lambda$ and is also denoted $\theta$. Let $V_\Lambda^+$ and $(V_\Lambda^T)^+$ be spaces of fixed points of $\theta$ in $V_\Lambda$ and $V_\Lambda^T$, respectively. Then the moonshine module is $V^\natural = V_\Lambda^+ \oplus (V_\Lambda^T)^+$ as a $\mathbb{Z}$-graded vector space. In [FLM2], the vertex operator map for the moonshine module is defined and it is shown that $V^\natural$ is indeed a vertex operator algebra.

The definition of vertex operator map for $V^\natural$ in [FLM2] uses some special features in the construction of the moonshine module, in particular, “triality” ([FLM1], [FLM2]). In fact, there is a conceptual way to define the vertex operator map which is motivated by the $S_3$-symmetry of the Jacobi identity and contragredient modules and which works also in much more general cases (see [FHL] and also [DGM] in physicists’ language). The hard part is to prove that the moonshine module together with this abstractly defined vertex operator map is a vertex operator algebra. This was first proved directly (i.e., without using triality, as had been done in [FLM2]) in [DGM] using techniques developed in string theory. Recently, this has also been proved conceptually by the author [Hu7] using the tensor product theory for modules for a vertex operator algebra developed by Lepowsky and the author [HL1] [HL4]–[HL7] [Hu6] [Hu8] and some results of Dong-Mason-Zhu [DMZ] and Dong [D1] on modules for the vertex operator algebra $V_\Lambda^*$. (Note that in more general cases in which we can still define the vertex operator maps abstractly, it is not always true that we will obtain a vertex operator algebra. In [DGM], a vertex operator algebra is obtained in a family of cases generalizing [FLM2].)

We now turn to the main subjects of this section. At the end of this section, we shall apply these results to the problem above. The material below in Section 1 is essentially taken from [FHL].

We first list some properties of the formal $\delta$-function and some easy consequences of the definition of vertex operator algebra. First there is the fundamental property of the $\delta$-function:

$$f(x)\delta(x) = f(1)\delta(x) \quad \text{for} \quad f(x) \in \mathbb{C}[x, x^{-1}] .$$ (1.1)
This property has many variants; in general, whenever an expression is multiplied by the δ-function, we may formally set the argument appearing in the δ-function equal to 1, provided the relevant algebraic expressions make sense. There are two basic identities for the δ-function:

\[ x_1^{-1} \delta \left( \frac{x_2 + x_0}{x_1} \right) = x_2^{-1} \delta \left( \frac{x_1 - x_0}{x_2} \right), \]  

\[ x_0^{-1} \delta \left( \frac{x_1 - x_2}{x_0} \right) - x_0^{-1} \delta \left( \frac{x_2 - x_1}{-x_0} \right) = x_2^{-1} \delta \left( \frac{x_1 - x_0}{x_2} \right). \]  

Let \((V, Y, 1, \omega)\) be a vertex operator algebra. We have the following immediate consequences of the definition of vertex operator algebra:

\[ [L(-1), Y(v, x)] = Y(L(-1)v, x), \]  

\[ [L(0), Y(v, x)] = Y(L(0)v, x) + xY(L(-1)v, x), \]  

\[ [L(1), Y(v, x)] = Y(L(1)v, x) + 2xY(L(0)v, x) + x^2Y(L(-1)v, x) \]  

for any \(v \in V\). From the \(L(-1)\)-derivative property and bracket formulas (1.4), we obtain

\[ e^{x_0L(-1)}Y(v, x)e^{-x_0L(-1)} = Y(e^{x_0L(-1)}v, x) = Y(v, x + x_0) \]  

Applying (1.7) to \(1\) and then taking the constant term in \(x_0\), we have

\[ Y(v, x)1 = e^{xL(-1)}v. \]

Finally, one very important consequence is the skew-symmetry, that is, for any \(u, v \in V\),

\[ Y(u, x)v = e^{xL(-1)}Y(v, -x)u. \]

We derive (1.9) as follows: We have

\[ x_0^{-1} \delta \left( \frac{x_1 - x_2}{x_0} \right) Y(u, x_1)Y(v, x_2) \]

\[ -x_0^{-1} \delta \left( \frac{x_2 - x_1}{-x_0} \right) Y(v, x_1)Y(u, x_2) \]

\[ = (-x_0)^{-1} \delta \left( \frac{x_2 - x_1}{-x_0} \right) Y(v, x_2)Y(u, x_1) \]

\[ -(-x_0)^{-1} \delta \left( \frac{x_1 - x_2}{-(-x_0)} \right) Y(u, x_1)Y(v, x_2). \]  

By the Jacobi identity and (1.10),

\[ x_2^{-1} \delta \left( \frac{x_1 - x_0}{x_2} \right) Y(Y(u, x_0)v, x_2) = x_1^{-1} \delta \left( \frac{x_2 - (-x_0)}{x_1} \right) Y(Y(v, -x_0)u, x_1). \]  

\[ (1.11) \]
Using the fundamental property of the $\delta$-function and the identity (1.2), we obtain
\[ x_2^{-1} \delta \left( \frac{x_1 - x_0}{x_2} \right) Y(Y(u, x_0)v, x_2) = x_2^{-1} \delta \left( \frac{x_1 - x_0}{x_2} \right) Y(Y(v, -x_0)u, x_2 + x_0). \] (1.12)

In particular (taking the coefficient of $x_1^{-1}$ in (1.12)),
\[ Y(Y(u, x_0)v, x_2) = Y(Y(v, -x_0)u, x_2 + x_0). \] (1.13)

But by the second equality in (1.7),
\[ Y(Y(v, -x_0)u, x_2 + x_0) = Y(e^{x_0L(-1)}Y(v, -x_0)u, x_2). \] (1.14)

By the creation property, (1.13) and (1.14),
\[ Y(u, x_0)v = \lim_{x_2 \to 0} Y(Y(u, x_0)v, x_2)1 \]
\[ = \lim_{x_2 \to 0} Y(e^{x_0L(-1)}Y(v, -x_0)u, x_2)1 \]
\[ = e^{x_0L(-1)}Y(v, -x_0)u. \] (1.15)

Now we discuss the $S_3$-symmetry of the Jacobi identity. For the Jacobi identity for Lie algebras, if we call
\[ [u, [v, w]] - [v, [u, w]] = [[u, v], w] \] (1.16)
“the Jacobi identity for the ordered triple $(u, v, w)$,” then the Jacobi identity for $(u, v, w)$ implies the Jacobi identity for any permutation of the ordered triple $(u, v, w)$. The $S_3$-symmetry for the Jacobi identity for vertex operator algebra is an analogous statement. (The analogy between Lie algebras and vertex operator algebras is the reason why Frenkel, Lepowsky and Meurman called the main axiom for vertex operator algebras the “Jacobi identity.” It would be more accurate and less confusing to call this identity the Frenkel-Lepowsky-Meurman identity or simply the FLM identity.) Let us retain the axioms for a vertex operator algebra except for the Jacobi identity, and let us call
\[ x_0^{-1} \delta \left( \frac{x_1 - x_2}{x_0} \right) Y(u, x_1)Y(v, x_2)w - x_0^{-1} \delta \left( \frac{x_2 - x_1}{x_0} \right) Y(v, x_2)Y(u, x_1)w \]
\[ = x_2^{-1} \delta \left( \frac{x_1 - x_0}{x_2} \right) Y(Y(u, x_0)v, x_2)w \] (1.17)
“the Jacobi identity for the ordered triple $(u, v, w)$.” We also assume that the consequences (1.7) and (1.9) hold. By skew-symmetry (1.9) for the pair $(u, v)$ and the second equality in (1.7) for the vector $Y(v, -x_0)u$ we have
\[ Y(Y(u, x_0)v, x_2) = Y(e^{x_0L(-1)}Y(v, -x_0)u, x_2) = Y(Y(v, -x_0)u, x_2 + x_0). \] (1.18)
Thus from (1.18) and the identity (1.2), the Jacobi identity (1.17) for \((u, v, w)\) gives
\[
(-x_0)^{-1} \delta \left( \frac{x_2 - x_1}{x_0} \right) Y(v, x_2)Y(u, x_1)w - (-x_0)^{-1} \delta \left( \frac{x_1 - x_2}{-x_0} \right) Y(u, x_1)Y(v, x_2)w \\
= x_1^{-1} \delta \left( \frac{x_2 - (-x_0)}{x_1} \right) Y(Y(v, -x_0)u, x_1)w,
\]
which is the Jacobi identity for \((v, u, w)\) (with \((x_1, x_2, x_0)\) replaced by \((x_2, x_1, -x_0))\).

On the other hand, multiplying both sides of the Jacobi identity (1.17) for \((u, v, w)\) by \(e^{-x_2L(-1)}\) and using (1.9) for the pairs \((v, w), (v, Y(u, x_1)w)\) and \((Y(u, x_0)v, w)\) and the outer equality in (1.7) for the vector \(u\), we obtain
\[
x_0^{-1} \delta \left( \frac{x_1 - x_2}{x_0} \right) Y(u, x_1 - x_2)Y(w, -x_2)v - x_0^{-1} \delta \left( \frac{x_2 - x_1}{-x_0} \right) Y(Y(u, x_1)w, -x_2)v \\
= x_2^{-1} \delta \left( \frac{x_1 - x_0}{x_2} \right) Y(w, -x_2)Y(u, x_0)v.
\]

Using the fundamental property of the \(\delta\)-function and (1.2), we can write (1.20) as
\[
x_1^{-1} \delta \left( \frac{x_0 + x_2}{x_1} \right) Y(u, x_0)Y(w, -x_2)v + x_2^{-1} \delta \left( \frac{x_0 - x_1}{-x_2} \right) Y(Y(u, x_1)w, -x_2)v \\
= x_1^{-1} \delta \left( \frac{-x_2 - (-x_0)}{-x_1} \right) Y(w, -x_2)Y(u, x_0)v,
\]
that is,
\[
x_1^{-1} \delta \left( \frac{x_0 - (-x_2)}{x_1} \right) Y(u, x_0)Y(w, -x_2)v \\
- x_1^{-1} \delta \left( \frac{(-x_2) - x_0}{-x_1} \right) Y(w, -x_2)Y(u, x_0)v \\
= (-x_2)^{-1} \delta \left( \frac{x_0 - x_1}{-x_2} \right) Y(Y(u, x_1)w, -x_2)v,
\]
the Jacobi identity for \((u, v, w)\) (and \((x_0, -x_2, x_1))\). Since the two permutation above of \((u, v, w)\) generate \(S_3\), the permutation group of \((u, v, w)\), we conclude:

**Proposition 1.1.** Under the assumptions indicated in the argument above, the Jacobi identity for an ordered triple implies the Jacobi identity for any permutation of this triple.

We turn next to the contragredient module for a module for a vertex operator algebra. Let \((W, Y)\), with
\[
W = \coprod_{n \in \mathbb{C}} W(n),
\]

be a module for a vertex operator algebra \((V,Y,1,\omega)\),

\[
W' = \prod_{n \in \mathbb{C}} W_{(n)^*}
\]  

(1.24)

the graded dual space of \(W\) and \(\langle \cdot, \cdot \rangle\) the pairing between \(W'\) and \(W\). We define the **contragredient vertex operators** \(Y'(v,x)\) \((v \in V)\) by means of the linear map

\[
V \rightarrow (\text{End } W')[[x,x^{-1}]]
\]

\[
v \mapsto Y'(v,x) = \sum_{n \in \mathbb{Z}} v'_n x^{-n-1} \quad \text{(where } v'_n \in \text{End } W')
\]  

(1.25)

determined by the condition

\[
\langle Y'(v,x)w',w \rangle = \langle w', Y(e^{xL(1)}(-x^{-2})L(0)v,x^{-1})w \rangle
\]  

(1.26)

for \(v \in V\), \(w' \in W'\), \(w \in W\). The operator \((-x^{-2})L(0)\) has the obvious meaning; it acts on a vector of weight \(n \in \mathbb{Z}\) as multiplication by \((-x^{-2})^n\). Also note that \(e^{xL(1)}(-x^{-2})L(0)v\) involves only finitely many (integral) powers of \(z\), that the right-hand side of (1.26) is a Laurent polynomial in \(x\), and that the components \(v'_n\) of the formal Laurent series \(Y'(v,x)\) defined by (1.26) indeed preserve \(W'\).

We give the space \(W'\) a \(\mathbb{C}\)-grading by setting

\[
W'_{(n)} = W^*_{(n)} \quad \text{for } n \in \mathbb{C}.
\]  

(1.27)

The following proposition defines the **\(V\)-module contragredient to \(W\):**

**Theorem 1.2.** The pair \((W',Y')\) carries the structure of a \(V\)-module.

**Proof.** The axioms on the grading are clear. For the Virasoro algebra properties, we note that

\[
\langle Y'(\omega,x)w',w \rangle = \langle w', Y(x^{-4}\omega,x^{-1})w \rangle
\]  

(1.28)

since

\[
L(1)\omega = L(-1)L(-2)1 = L(-2)L(-1)1 = 0.
\]  

(1.29)

Thus, defining component operators \(L'(n)\) by

\[
Y'(\omega,x) = \sum_{n \in \mathbb{Z}} L'(n)x^{-n-2},
\]  

(1.30)
we have

\[ \langle \sum_{n \in \mathbb{Z}} L'(n)x^{-n}w', w \rangle = \]
\[ = \langle x^2 Y'(\omega, x)w', w \rangle \]
\[ = \langle w', x^{-2} Y(\omega, x^{-1})w \rangle \]
\[ = \langle w', \sum_{n \in \mathbb{Z}} L(-n)x^{-n}w \rangle, \]
\[ (1.31) \]

and so

\[ \langle L'(n)w', w \rangle = \langle w', L(-n)w \rangle \text{ for } n \in \mathbb{Z}. \]
\[ (1.32) \]

This immediately gives us the Virasoro commutator relation for \( L'(n), n \in \mathbb{Z}. \)

We shall give proofs of the Jacobi identity and the \( L(-1) \)-derivative property. For these two axioms, we shall use some commutator formulas motivated by the Lie group \( \text{SL}(2, \mathbb{C}) \), but formulated and proved in terms of formal series. We shall omit the proofs of these formulas; they can be found in [FHL] and are all direct calculations.

**Lemma 1.3.** Let

\[ f(x) \in x \mathbb{C}[[x]]. \]
\[ (1.33) \]

We have the following identities, valid on any module for the Lie algebra \( \mathfrak{sl}(2) \) spanned by \( L(-1), L(0), L(1) \):

\[ L(-1)e^{f(x)L(0)} = e^{f(x)L(0)}L(-1)e^{-f(x)}, \]
\[ (1.34) \]

\[ L(1)e^{f(x)L(0)} = e^{f(x)L(0)}L(1)e^{f(x)}, \]
\[ (1.35) \]

\[ L(-1)e^{f(x)L(1)} = \]
\[ = e^{f(x)L(1)}L(-1) - 2f(x)L(0)e^{f(x)L(1)} - f(x)^2 L(1)e^{f(x)L(1)} \]
\[ = e^{f(x)L(1)}L(-1) - 2f(x)e^{f(x)L(1)}L(0) + f(x)^2 e^{f(x)L(1)}L(1). \]
\[ (1.36) \]

These identities also hold for more general \( f \) for which the series are well defined, such as

\[ f(x, x_0) \in x \mathbb{C}[[x, x_0]]. \]
\[ (1.37) \]
Now we establish the $L(-1)$-derivative property. For convenience, we assume that $v \in V$ is homogeneous of weight $n \in \mathbb{Z}$: $L(0)v = nv$. Using the definition $Y'(\cdot, x)$ and the chain rule we get

$$
\frac{d}{dx} Y'(v, x)w', w) = \\
= \frac{d}{dx} Y'(e^{xL(1)}(-x^{-2})L(0)v, x^{-1})w) \\
= \langle w', \frac{d}{dx} Y(e^{xL(1)}(-x^{-2})L(0)v, x^{-1})w) \\
= \langle w', Y(\frac{d}{dx} e^{xL(1)}(-x^{-2})L(0)v, x^{-1})w) \\
+ \langle w', \frac{d}{dx} Y(v_1, x^{-1}) \mid \rangle_{v_1 = e^{xL(1)}(-x^{-2})L(0)v, w),}
$$

where $w'$ and $w$ are arbitrary elements of $W'$ and $W$, respectively. We perform the indicated calculations:

$$
\frac{d}{dx} (e^{xL(1)}(-x^{-2})L(0)) = \\
= L(1)e^{xL(1)}(-x^{-2})L(0) - 2x^{-1}e^{xL(1)}L(0)(-x^{-2})L(0),
$$

$$
\frac{d}{dx} Y(v_1, x^{-1}) \mid \rangle_{v_1 = e^{xL(1)}(-x^{-2})L(0)v} = \\
= -x^{-2} \frac{d}{dx-1} Y(v_1, x^{-1}) \mid \rangle_{v_1 = e^{xL(1)}(-x^{-2})L(0)v} \\
= -x^{-2} Y(L(-1)v_1, x^{-1}) \mid \rangle_{v_1 = e^{xL(1)}(-x^{-2})L(0)v} \\
= -x^{-2} Y((e^{xL(1)}L(-1) - 2xe^{xL(1)}L(0) \\
+ x^2 L(1)e^{xL(1)}(-x^{-2})v, x^{-1}) \\
= Y((e^{xL(1)}(-x^{-2})v, x^{-1}) \\
+ Y(2x^{-1}e^{xL(1)}L(0)(-x^{-2})v, x^{-1}) \\
- Y(L(1)e^{xL(1)}(-x^{-2})v, x^{-1}) \\
= Y((e^{xL(1)}(-x^{-2})v, x^{-1}) \\
+ Y(2x^{-1}e^{xL(1)}L(0)(-x^{-2})v, x^{-1}) \\
- Y(L(1)e^{xL(1)}(-x^{-2})v, x^{-1}).
$$

Here we have used the outer equality in (1.36) and the fact that

$$
L(0)L(-1)v = L(-1)(L(0) + 1)v = (n + 1)L(-1)v.
$$
Substituting (1.39) and (1.40) into (1.38) we get

\[
\left\langle \frac{d}{dx}Y'(v, x)w', w \right\rangle = \\
= \left\langle w', Y(L(1)e^{xL(1)}(-x^{-2})L(0)v \\
-2x^{-1}e^{xL(1)}L(0)(-x^{-2})L(0)v, x^{-1})w' \right\rangle \\
+ \left\langle w', Y(e^{xL(1)}(-x^{-2})L(0)L(-1)v, x^{-1})w' \right\rangle \\
+ \left\langle w', Y(2x^{-1}e^{xL(1)}L(0)(-x^{-2})L(0)v, x^{-1})w' \right\rangle \\
- \left\langle w', Y(L(1)e^{xL(1)}(-x^{-2})L(0)v, x^{-1})w' \right\rangle \\
= \left\langle w', Y(e^{xL(1)}(-x^{-2})L(0)L(-1)v, x^{-1})w' \right\rangle \\
= \left\langle Y'(-1)v, x)w', w \right\rangle,
\]
proving the \(L(-1)\)-derivative property.

Finally, we shall prove the Jacobi identity. Let \(v_1, v_2 \in V, w \in W\) and \(w' \in W'\). What we want to prove can be written as follows:

\[
\left\langle x_0^{-1}\delta \left(\frac{x_1 - x_2}{x_0}\right) Y'(v_1, x_1)Y'(v_2, x_2)w', w \right\rangle \\
= \left\langle x_0^{-1}\delta \left(\frac{x_2 - x_1}{x_0}\right) Y'(v_2, x_2)Y'(v_1, x_1)w', w \right\rangle \\
= \left\langle x_2^{-1}\delta \left(\frac{x_1 - x_0}{x_2}\right) Y'(Y(v_1, x_0)v_2, x_2)w', w \right\rangle.
\]

But by the definition (1.26) of contragredient vertex operator, we have

\[
\left\langle Y'(v_1, x_1)Y'(v_2, x_2)w', w \right\rangle = \left\langle w', Y(x_2L(1)(-x_2^{-2})L(0)v_2, x_2^{-1})Y(x_1L(1)(-x_1^{-2})L(0)v_1, x_1^{-1})w \right\rangle
\]

\[
\left\langle Y'(v_2, x_2)Y'(v_1, x_1)w', w \right\rangle = \left\langle w', Y(x_2L(1)(-x_2^{-2})L(0)v_1, x_1^{-1})Y(x_1L(1)(-x_1^{-2})L(0)v_2, x_2^{-1})w \right\rangle
\]

\[
\left\langle Y'(Y(v_1, x_0)v_2, x_2)w', w \right\rangle = \left\langle w', Y(x_2L(1)(-x_2^{-2})L(0))Y(v_1, x_0)v_2, x_2^{-1})w \right\rangle,
\]

(1.42)
and from the Jacobi identity for $W$ we have
\[
\langle w', \left( \frac{-x_0}{x_1x_2} \right)^{-1} \delta \left( \frac{x_2 - x_1}{-x_0/x_1x_2} \right) \rangle Y(e^{x_1L(1)}(-x_1^{-2}L(0)v_1, x_1^{-1})).
\]
\[
\cdot Y(e^{x_2L(1)}(-x_2^{-2}L(0)v_2, x_2^{-1}))w
\]
\[
= \langle w', (x_2^{-1}x_0/x_1x_2)^{-1} \delta \left( \frac{x_2 - x_1}{x_0/x_1x_2} \right) \rangle Y(e^{x_2L(1)}(-x_2^{-2}L(0)v_2, x_2^{-1}))w
\]
\[
= \langle w', (x_2^{-1}x_0/x_1x_2)^{-1} \delta \left( \frac{x_2 + x_0}{x_2} \right) \rangle Y(e^{x_2L(1)}(-x_2^{-2}L(0)v_2, x_2^{-1}))w
\]
\[
= \langle w', (x_2^{-1}x_0/x_1x_2)^{-1} \delta \left( \frac{x_2 + x_0}{x_1} \right) \rangle Y(e^{x_2L(1)}(-x_2^{-2}L(0)v_2, x_2^{-1}))w.
\]
(1.47)

or equivalently,
\[
-\langle w', x_0^{-1} \delta \left( \frac{x_2 - x_1}{-x_0} \right) \rangle Y(e^{x_1L(1)}(-x_1^{-2}L(0)v_1, x_1^{-1})).
\]
\[
\cdot Y(e^{x_2L(1)}(-x_2^{-2}L(0)v_2, x_2^{-1}))w
\]
\[
+ \langle w', x_0^{-1} \delta \left( \frac{x_1 - x_2}{x_0} \right) \rangle Y(e^{x_2L(1)}(-x_2^{-2}L(0)v_2, x_2^{-1})w
\]
\[
= \langle w', x_0^{-1} \delta \left( \frac{x_2 + x_0}{x_1} \right) \rangle \cdot Y(e^{x_2L(1)}(-x_2^{-2}L(0)v_2, x_2^{-1})w.
\]
(1.48)

(As usual, the reader should be observing that the formal Laurent series which arise are well defined.) Thus (by (1.2)) the desired result (1.43) is equivalent to
\[
x_1^{-1} \delta \left( \frac{x_2 + x_0}{x_1} \right) Y(e^{x_2L(1)}(-x_2^{-2}L(0)v_1, x_0)v_2, x_2^{-1})
\]
\[
= x_1^{-1} \delta \left( \frac{x_2 + x_0}{x_1} \right) Y(e^{x_1L(1)}(-x_1^{-2}L(0)v_1, -x_0/x_1x_2) \cdot e^{x_2L(1)}(-x_2^{-2}L(0)v_2, x_2^{-1})w.
\]
(1.49)

or to
\[
Y(e^{x_2L(1)}(-x_2^{-2}L(0)v_1, x_0)v_2, x_2^{-1})
\]
\[
= Y(e^{(x_2 + x_0)L(1)}(-x_2 + x_0)^{-2}L(0)v_1, -x_0/(x_2 + x_0)x_2) \cdot e^{x_2L(1)}(-x_2^{-2}L(0)v_2, x_2^{-1})w.
\]
(1.50)
If we can prove
\[
e^{x_2 L(1)} (-x_2^{-2} L(0)) Y(v_1, x_0) = Y(e^{x_2 + x_0} L(1) (-x_2 + x_0)^{-2} L(0) v_1, -x_0/(x_2 + x_0)x_2) \cdot e^{x_2 L(1)} (-x_2^{-2} L(0)) \tag{1.51}
\]
or equivalently, the conjugation formula
\[
e^{x L(1)} (-x^{-2} L(0)) Y(v, x_0) (-x^{-2} L(0) e^{-x L(1)} \tag{1.52}
\]
for any element \( v \) of a vertex operator algebra, where the operators act on the algebra itself, then we will be done. But for this, it is sufficient to prove the following lemma:

**Lemma 1.4.** Let \( V \) be a vertex operator algebra. The following conjugation formulas hold on \( V \):
\[
\begin{align*}
x L(0) Y(v, x_0) x^{-L(0)} &= Y(x L(0) v, xx_0) \tag{1.53} \\
e^{x L(1)} Y(v, x_0) e^{-x L(1)} &= Y(e^{x_0 L(1) (1 - xx_0)^{-2} L(0) v, x_0/(1 - xx_0)}). \tag{1.54}
\end{align*}
\]

The proof of this lemma, which we omit here, can be found in [FHL]. This finishes the proof of the theorem. \( \square \)

The functor taking a \( V \)-module to its contragredient module has some important properties which we state without proof (see [FHL]):

**Proposition 1.5.** There is a natural isomorphism between the double contragredient module \( (W'', Y'') \) and \( (W, Y) \).

**Proposition 1.6.** The module \( (W, Y) \) is irreducible if and only if \( (W', Y') \) is irreducible.

**Proposition 1.7.** The module \( (W, Y) \) is isomorphic to its contragredient module \( (W', Y') \) if and only if there exists a nondegenerate bilinear form \( (\cdot, \cdot)_W \) on \( W \) such that
\[
(W_m, W_n)_W = 0, \quad m \neq n \tag{1.55}
\]
and
\[
(Y'(v, x) w_1, w_2)_W = (w_1, Y(e^{x L(1)} (-x^{-2} L(0) v, x^{-1}) w_2)_W. \tag{1.56}
\]
If \( V \) as a \( V \)-module is isomorphic to \( V' \), the bilinear form \( (\cdot, \cdot)_V \) is symmetric.
We return to our problem of defining the vertex operator map for \( V^\natural \). Let \( V \) be a vertex operator algebra and \( W \) a \( V \)-module. Assume that both \( V \) and \( W \) as \( V \)-modules are isomorphic to themselves. By Proposition 1.7, there are nondegenerate bilinear forms \( (\cdot,\cdot)_V \) and \( (\cdot,\cdot)_W \) satisfying the two conditions in Proposition 1.7. In addition, \( (\cdot,\cdot)_V \) is symmetric. Assume that there is a vertex operator map 

\[
Y_{V \oplus W} : (V \oplus W) \otimes (V \oplus W) \to (\text{End} \ (V \oplus W))[x,x^{-1}]
\]

such that \( (V \oplus W, Y_{V \oplus W}, 1, \omega) \) (1 and \( \omega \) are the vacuum and the Virasoro element of \( V \), respectively) is a vertex operator algebra satisfying the following:

1. The vertex operator algebra structure on \( V \) and the module structure on \( W \) are substructures of it.
2. As a module for itself, it is isomorphic its contragredient module and the corresponding symmetric nondegenerate bilinear form \( (\cdot,\cdot)_{V \oplus W} \) is defined by

\[
((v_1,w_2),(v_2,w_2))_{V \oplus W} = (v_1,v_2)_V + (w_1,w_2)_W
\]

for all \( v_1,v_2 \in V \) and \( w_1,w_2 \in W \).
3. The involution which is the identity on \( V \) and is \(-1\) on \( W \) is an automorphism of \( (V \oplus W, Y_{V \oplus W}, 1, \omega) \).

Then we must have the following:

1. The module \( W \) is \( \mathbb{Z} \)-graded.
2. The bilinear form \( (\cdot,\cdot)_W \) is symmetric.
3. We have the following formulas: For any \( v \in V \) and \( w \in W \),

\[
Y_{V \oplus W}(w,x)v = e^{xL(-1)}Y_W(v,-x)w
\]

and for any \( v \in V \), \( w_1,w_2,w_3 \in W \),

\[
(w_3,Y_{V \oplus W}(w_1,x)w_2)_W = 0,
\]

\[
(v,Y_{V \oplus W}(w_1,x)w_2)_V = (Y_W(v,-x^{-1})e^{xL(1)}(-x^2)^{-L(0)}w_1,e^{x^{-1}L(1)}w_2)_W,
\]

where \( Y_V \) and \( Y_W \) are the vertex operator maps for \( V \) and \( W \), respectively.

We see that the vertex operator map \( Y_{V \oplus W} \) is determined completely by the vertex operator maps \( Y_V \), \( Y_W \), the bilinear forms \( (\cdot,\cdot)_V \), \( (\cdot,\cdot)_W \) and (1.58)–(1.60). Thus even if we do not know whether \( V \oplus W \) is such a vertex operator algebra, we can still define a vertex operator map \( Y_{V \oplus W} \) using \( Y_V \), \( Y_W \), the bilinear forms \( (\cdot,\cdot)_V \), \( (\cdot,\cdot)_W \) and (1.58)–(1.60). In particular, since \( V_A^+ \) and \( (V_A^T)^+ \) as \( V_A^+ \)-modules are both isomorphic to their contragredient modules, we can define a vertex operator map \( Y_{V^2} \) for \( V^2 = V_A^+ \oplus (V_A^T)^+ \).
2. INTERTWINING OPERATORS, FUSION RULES AND VERLINDE ALGEBRAS

We first define intertwining operators and fusion rules for a vertex operator following [FHL].

Let

\[ V\{x\} = \left\{ \sum_{n \in \mathbb{C}} v_n x^n | v_n \in V \right\} \]  

be the vector space of \( V \)-valued formal series involving the complex powers of \( x \) with coefficients in a vector space \( V \).

**Definition 2.1.** Let \( V \) be a vertex operator algebra and let \((W_1,Y_1),(W_2,Y_2)\) and \((W_3,Y_3)\) be three \( V \)-modules (not necessarily distinct, and possibly equal to \( V \)). An **intertwining operator of type** \( \left( \begin{array}{c} 3 \\ 12 \end{array} \right) \) (or of type \( \left( \begin{array}{c} W_3 \\ W_1 W_2 \end{array} \right) \)) is a linear map \( W_1 \otimes W_2 \rightarrow W_3\{x\} \), or equivalently,

\[ W_1 \rightarrow (\text{Hom}(W_2,W_3))\{x\} \]
\[ w \mapsto \mathcal{Y}(w,x) = \sum_{n \in \mathbb{Q}} w_n x^{-n-1} \quad (\text{where } w_n \in \text{Hom}(W_2,W_3)) \]  

such that “all the defining properties of a module action that make sense hold” (cf. the definition of \( V \)-module). That is, for \( v \in V \), \( w_{(1)} \in W_1 \) and \( w_{(2)} \in W_2 \),

\[ w_{(1)n} w_{(2)} = 0 \quad \text{for } n \text{ whose real part is sufficiently large}; \]  

the following Jacobi identity holds for the operators \( Y_i(v,\cdot), i = 1,2,3, \mathcal{Y}(w_{(1)},\cdot) \) acting on the element \( w_{(2)} \):

\[ x_0^{-1} \delta \left( \frac{x_1 - x_2}{x_0} \right) Y_3(v,x_1) \mathcal{Y}(w_{(1)},x_2) w_{(2)} \]
\[ -x_0^{-1} \delta \left( \frac{x_2 - x_1}{-x_0} \right) \mathcal{Y}(w_{(1)},x_2) Y_2(v,x_1) w_{(2)} \]
\[ = x_2^{-1} \delta \left( \frac{x_1 - x_0}{x_2} \right) \mathcal{Y}(Y_1(v,x_0)w_{(1)},x_2) w_{(2)} \]  

(note that the first term on the left-hand side is algebraically meaningful because of condition (2.3), and the other terms are meaningful by the usual properties of modules; also note that this Jacobi identity involves integral powers of \( x_0 \) and \( x_1 \) and complex powers of \( x_2 \));

\[ \frac{d}{dx} \mathcal{Y}(w_{(1)},x) = \mathcal{Y}(L(-1)w_{(1)},x), \]  

where \( L(-1) \) is the operator acting on \( W_1 \).
We may denote the intertwining operator just defined by
\[ \mathcal{V}^3_{12} \] or \[ \mathcal{V}^W_{W_1 W_2}, \] if necessary, to indicate its type.

Note that \( Y(\cdot, x) \) acting on \( V \) is an example of an intertwining operator of type \( (V \ V \ V) \), and \( Y(\cdot, x) \) acting on a \( V \)-module \( W \) is an example of an intertwining operator of type \( (W \ V \ W) \). These intertwining operators satisfy the normalization condition \( Y(1, x) = 1 \).

The intertwining operators of type \( (3 \ 1 \ 2) \) clearly form a vector space, which we denote by \( \mathcal{V}^3_{12} \) or \( \mathcal{V}^W_{W_1 W_2} \). We set
\[ N^3_{12} = N^W_{W_1 W_2} = \dim \mathcal{V}^3_{12} \leq \infty. \] (2.7)

These numbers are called the fusion rules associated with the algebra and modules. Then for example, assuming that \( V \) and the \( V \)-module \( W \) are nonzero, the corresponding fusion rules are positive:
\[ N^V_{VV} \geq 1, \] \[ N^W_{VW} \geq 1, \] \[ N^W_{WW} \geq 1. \] (2.8, 2.9, 2.10)

In [FHL] and [HL5], it is shown that the fusion rules have the following symmetry property: Define
\[ N_{ijk} = N_{W_i W_j W_k} = N^W_{W_i W_j} \] (2.11)
for \( i, j, k = 1, 2, 3 \). Then for any element \( \sigma \in S_3 \), we have
\[ N_{\sigma(1) \sigma(2) \sigma(3)} = N_{123}. \] (2.12)

If the vertex operator algebra \( V \) is rational, that is, \( V \) satisfies the conditions: (i) there are only finitely many irreducible \( V \)-modules (up to equivalence), (ii) every \( V \)-module is completely reducible, (iii) all the fusion rules are finite, then we can define an algebra called the fusion algebra or the Verlinde algebra using fusion rules for the irreducible modules as follows: Assume that there are \( m \) inequivalent irreducible \( V \)-modules. Let \( A \) be the abelian group tensor product of the \( K \)-group of the \( V \)-modules with \( \mathbb{C} \). Then \( A \) has a natural structure of a vector space. Since \( V \) is rational, we have
\[ A = \sum_{i=1}^m \mathbb{C} \phi_i \] (2.13)
where \( \phi_i, i = 1, \ldots, m, \) are all the equivalence classes containing irreducible modules. We define a product on \( A \) by

\[
\phi_i \cdot \phi_j = \sum_{k=1}^{m} N_{ij}^{k} \phi_k
\]

for all \( i, j = 1, \ldots, m, \) where \( N_{ij}^{k}, 1 \leq i, j, k \leq m, \) are the fusion rules \( N_{W_i W_j}^{W_k} \) for any \( W_i \in \phi_i, W_j \in \phi_j \) and \( W_k \in \phi_k. \) By the symmetry \((2.12)\), it is clear that this product is commutative. When the intertwining operators for the vertex operator algebra satisfy certain additional conditions, it can be proved that this product is also associative. One condition that we need is that all irreducible \( V \)-modules are \( \mathbb{R} \)-graded. If \( V \) is rational, then this condition implies that every \( V \)-module is \( \mathbb{R} \)-graded, that is, the weight of an element of a \( V \)-module is always a real number. We also need an additional condition. Given any \( V \)-modules \( W_1, W_2, W_3, W_4 \) and \( W_5, \) let \( \mathcal{Y}_1, \mathcal{Y}_2, \mathcal{Y}_3 \) and \( \mathcal{Y}_4 \) be intertwining operators of type \( \left( \frac{W_4}{W_1 W_3}, \left( \frac{W_5}{W_2 W_3} \right), \left( \frac{W_5}{W_1 W_2} \right) \right) \) and \( \left( \frac{W_4}{W_5 W_3} \right), \) respectively. Consider the following conditions for the product of \( \mathcal{Y}_1 \) and \( \mathcal{Y}_2 \) and for the iterate of \( \mathcal{Y}_3 \) and \( \mathcal{Y}_4, \) respectively:

**Convergence and extension property for products**: There exists an integer \( N \) (depending only on \( \mathcal{Y}_1 \) and \( \mathcal{Y}_2 \)), and for any \( w_{(1)} \in W_1, w_{(2)} \in W_2, w_{(3)} \in W_3, w_{(4)}' \in W_4', \) there exist \( j \in \mathbb{N}, r_i, s_i \in \mathbb{R}, i = 1, \ldots, j, \) and analytic functions \( f_i(z) \) on \( |z| < 1, \) \( i = 1, \ldots, j, \) satisfying

\[
\text{wt } w_{(1)} + \text{wt } w_{(2)} + s_i > N, \quad i = 1, \ldots, j, \tag{2.15}
\]

such that

\[
\left\langle w_{(4)}, \mathcal{Y}_1(w_{(1)}, x_2) \mathcal{Y}_2(w_{(2)}, x_2) w_{(3)} \right\rangle_{W_4}
\]

\[
|z_1| = e^{n \log z_1}, x_2 = e^{n \log z_2}, z \in \mathbb{C}
\]

is convergent when \( |z_1| > |z_2| > 0 \) and can be analytically extended to the multi-valued analytic function

\[
\sum_{i=1}^{j} z_2^{r_i}(z_1 - z_2)^{s_i} f_i \left( \frac{z_1 - z_2}{z_2} \right) \tag{2.17}
\]

when \( |z_2| > |z_1 - z_2| > 0. \)

**Convergence and extension property for iterates**: There exists an integer \( N \) (depending only on \( \mathcal{Y}_3 \) and \( \mathcal{Y}_4 \)), and for any \( w_{(1)} \in W_1, w_{(2)} \in W_2, w_{(3)} \in W_3, w_{(4)}' \in W_4', \) there exist \( k \in \mathbb{N}, \tilde{r}_i, \tilde{s}_i \in \mathbb{R}, i = 1, \ldots, k, \) and analytic functions \( \tilde{f}_i(z) \) on \( |z| < 1, \) \( i = 1, \ldots, k, \) satisfying

\[
\text{wt } w_{(2)} + \text{wt } w_{(3)} + \tilde{s}_i > N, \quad i = 1, \ldots, k, \tag{2.18}
\]
such that
\[
\langle w'_4, Y_4(Y_3(w_1(x_0)), x_2), w_3(x_2) \rangle_{W_4}
\]
(2.19)

is convergent when \(|z_2| > |z_1 - z_2| > 0\) and can be analytically extended to the multi-valued analytic function
\[
\sum_{i=1}^{k} z_1^{s_i} z_2^{t_i} f_i \left( \frac{z_2}{z_1} \right)
\]
(2.20)

when \(|z_1| > |z_2| > 0\).

If for any \(V\)-modules \(W_1, W_2, W_3, W_4\) and \(W_5\) and any intertwining operators \(Y_1\) and \(Y_2\) of the types as above, the convergence and extension property of products holds, we say that the products of the intertwining operators for \(V\) have the convergence and extension property. Similarly we can define the meaning of the phrase the iterates of the intertwining operators for \(V\) have the convergence and extension property.

We also need the notion of generalized module: A generalized \(V\) module is a pair \((W, Y)\) satisfying all the axioms for a \(V\)-module except the two grading axioms: \(\dim W_n < \infty\) for all \(n \in \mathbb{C}\) and \(W_n = 0\) for \(n \in \mathbb{C}\) whose real part is sufficiently small. If a generalized \(V\)-module \(W = \bigoplus_{n \in \mathbb{C}} W_n\) satisfies the second grading axiom above, we say that \(W\) is lower-truncated. We have the following result:

**Theorem 2.1.** Let \(V\) be a rational vertex operator algebra for which all irreducible modules are \(\mathbb{R}\)-graded. Assume that \(V\) satisfies the following conditions:

1. Every finitely-generated lower-truncated generalized \(V\)-module is a \(V\)-module.
2. The products or the iterates of the intertwining operators for \(V\) have the convergence and extension property.

Then the Verlinde algebra for \(V\) is a commutative associative algebra with unit.

This theorem is an easy consequence of the associativity of the tensor product theory for modules for a vertex operator algebra developed by Lepowsky and the author [HL1]–[HL7] [Hu6].

Fusion rules and Verlinde algebras are very important concepts and tools in the study of conformal field theory. One of the most interesting results in the mathematical study of conformal field theory is that the fusion rules and their higher-genus generalizations for the WZNW conformal field theory can be expressed in terms of elementary functions (actually, the sine functions) [Ve]. On the other hand, these fusion rules and generalizations can also be shown to be equal to the dimensions of the space of “generalized theta functions” on the moduli spaces of semistable principal bundles on smooth projective irreducible algebraic curves [KNR]. Thus one obtains a simple and beautiful formula for these dimensions. These are the so called Verlinde
formulas. Mathematical proofs of these formulas have been obtained in [TUY] and [Fa].

3. Geometric interpretation of vertex operator algebras

We give a brief description of the geometric interpretation of vertex operator algebras in this section. The geometric interpretations of vertex operators, their duality properties and their transformation properties under the projective transformations were first given by Frenkel [Fr] using the geometry of $\mathbb{C} \cup \{\infty\}$ with some discs deleted. The complete geometric interpretation is obtained in [Hu1] and [Hu9]. The formulation using operads is given in [HL2] and [HL3]. See [Hu1]–[Hu4], [Hu9], [HL2] and [HL3] for details and other expositions.

In classical algebraic theories we study mostly algebraic structures defined by binary operations. These binary operations can always be described by one-dimensional geometric objects. For example, Lie algebras can be described by binary trees. A Lie algebra can be defined to be a “linear representation” of the moduli space of binary trees with a “welding operation,” satisfying certain “conservation” and “orientation” properties [Hu1] [Hu5]. Any associative binary operation, for example, the multiplication for a group or an algebra, can be described using the moduli space of circles with punctures and local coordinates [HL2] [HL3]. The general philosophy behind the geometric interpretation of vertex operator algebras is to study certain two-dimensional analogues of the classical binary operations, that is, to study operations described by two-dimensional analogues of binary trees or circles with punctures and local coordinates.

The two-dimensional analogues, used to describe vertex operator algebras, of both binary trees and circles with punctures and local coordinates are spheres with analytically parametrized boundaries, where by spheres we mean one-dimensional compact connected genus-zero complex manifolds. These spheres with boundaries are in some sense equivalent to spheres with ordered points (which are called punctures), one negatively oriented and others positively oriented, and local coordinates vanishing at these points, as is explained in [Hu1] and [Hu9]. We will use the the index 0 to denote the negatively oriented puncture on such a sphere with punctures and local coordinates. Let $S_1$ and $S_2$ be two such spheres with punctures and local coordinates, $p_j$, $j = 0, \ldots, m$, the punctures of $S_1$, $q_k$, $k = 0, \ldots, n$, the punctures of $S_2$, $(U_j, \varphi_j)$, $j = 0, \ldots, m$, the local coordinates vanishing at $p_j$ and $(V_k, \psi_k)$, $k = 0, \ldots, n$, the local coordinates vanishing at $q_k$. For any integer $i$ satisfying $0 < i \leq n$, we would like to sew $S_1$ and $S_2$ through the $i$-th puncture of $S_1$ and the 0-th puncture of $S_2$ to obtain a new spheres with punctures and local coordinates. Assume that there exists a positive number $r$ such that $\varphi_i(U_i)$ contains the closed disc $\bar{B}_0^r$ centered at 0 with radius $r$ and $\psi_0(V_0)$ contains the closed disc $\bar{B}_0^{1/r}$ centered at 0 with radius $1/r$. Assume also that $p_i$ and $q_0$ are the only punctures in $\varphi_i^{-1}(\bar{B}_0^r)$ and $\psi_0^{-1}(\bar{B}_0^{1/r})$. 
 respectively. In this case we say that the \textit{i-th puncture of \(S_1\) can be sewn with the \(0\)-th puncture of \(S_2\)}. In this case, we obtain a sphere with \(n + m + 1\) punctures and local coordinates by cutting \(\varphi_i^{-1}(B_0^r)\) and \(\psi_0^{-1}(B_0^{3/2})\) from \(S_1\) and \(S_2\), respectively, and then identifying the boundaries of the resulting surfaces using the map \(\varphi_i \circ \gamma \circ \psi_0^{-1}\) where \(\gamma\) is the map from \(\mathbb{C} \setminus \{0\}\) to itself defined by \(\gamma(z) = 1/z\). The punctures (with ordering) of this sphere with punctures and local coordinates are \(p_0, \ldots, p_{i-1}, q_1, \ldots, q_n, p_{i+1}, \ldots, p_m\). The local coordinates vanishing at these punctures are given in the obvious way. Thus we have a partial operation. Given two such spheres with punctures and local coordinates, \(S_1\) and \(S_2\), with the same number of punctures, if there is a analytic isomorphism from the underlying sphere of \(S_1\) to the underlying sphere of \(S_2\) such that the ordered punctures of \(S_1\) are mapped to the ordered punctures of \(S_2\) and the germs containing the pull-backs of the local coordinates of \(S_2\) are the same as the germs containing the local coordinates of \(S_1\), we say that \(S_1\) and \(S_2\) are \textit{conformally equivalent}. This is an equivalence relation. The space of conformal equivalence classes of such spheres with punctures and local coordinates is called the \textit{moduli space of spheres with punctures and local coordinates}.

The moduli space of spheres with \(n + 1\) punctures and local coordinates \((n \geq 1)\) can be identified with \(K(n) = M^{n-1} \times H \times H_c^n\) where \(H\) is the set of all sequences \(A\) of complex numbers such that \(\exp(\sum_{j=1}^{\infty} A_j x^{j+1} \frac{d}{dx}) \cdot x\) is a convergent power series in some neighborhood of \(0\), \(H_c = \mathbb{C}^\times \times H\), and \(M^{n-1}\) is the subset of elements in \(\mathbb{C}^{n-1}\) with nonzero and distinct components. The moduli space of spheres with one puncture and local coordinates can be identified with \(K(0) = \{B \in H \mid B_1 = 0\}\). Then the moduli space of spheres with punctures and local coordinates can be identified with \(\cup_{n=1}^{\infty} K(n)\). From now on we will refer to \(K(n)\), \(n \in \mathbb{N}\) as the moduli space of spheres with \(n + 1\) punctures and local coordinates. The sewing operation for spheres with punctures and local coordinates induces a partial operation on \(\cup_{n=1}^{\infty} K(n)\). It is still called the \textit{sewing operation} and is denoted \(\circ\). Note that there is an obvious action of \(S_n\) on \(K(n)\) by permuting the ordering of the \(n\) positively oriented punctures and local coordinates.

Now we have a sequences of sets \(K = \{K_n\}_{n=1}^{\infty}\) together with partial operations \(\circ\) and actions of \(S_n\) on \(K(n), n \in \mathbb{Z}_+,\) respectively. It is easy to show that the sewing operations satisfy the following conditions when the sewing operations appearing in the equations below exist:

(1) For any \(j \in \mathbb{Z}_+, k, l \in \mathbb{N}, i_1, 1 \leq i_1 \leq j, i_2, 1 \leq i_2 \leq j + k - 1, Q_1 \in K(j), Q_2 \in K(k), Q_3 \in K(l),\)

\[
(Q_{1, i_1} \circ \circ \circ Q_2)_{i_2} \circ \circ \circ Q_3 = \begin{cases} (Q_{1, i_2} \circ \circ \circ Q_3)_{i_1 + i_1 - 1} \circ \circ \circ Q_2, & i_2 < i_1, \\ Q_{1, i_1} \circ \circ \circ (Q_{2, i_2 - i_1 + 1} \circ \circ \circ Q_3), & i_1 \leq i_2 < i_1 + k, \\ (Q_{1, i_2 - j} \circ \circ \circ Q_3)_{i_1} \circ \circ \circ Q_2, & i_1 + k \leq i_2. \end{cases}
\]  

(3.1)
(2) For any \( j \in \mathbb{Z}_+, k \in \mathbb{N}, i, 1 \leq i \leq k, Q_1 \in K(j), Q_2 \in K(k), \sigma \in S_j \) and \( \tau \in S_k, \)

\[
\sigma(Q_1)_i\infty_0 Q_2 = \sigma(1, \ldots, 1, k, 1, \ldots, 1)(Q_1)_i\infty_0 Q_2), \quad (3.2)
\]

\[
Q_1\infty_0 \tau Q_2 = (1 \oplus \cdots \oplus 1 \oplus \tau \oplus 1 \oplus \cdots \oplus 1)(Q_1\infty_0 Q_2). \quad (3.3)
\]

(3) Let \( I = (0, (1, 0)) \in H \times (\mathbb{C}^\times \times H) = K(1). \) Then for any \( k \in \mathbb{N}, i, 1 \leq i \leq k, Q \in K(k), \)

\[
Q_i\infty_0 I = I_i\infty_0 Q = Q. \quad (3.4)
\]

A sequence \( \{\mathcal{X}(j)\}_{j \in \mathbb{N}} \) of sets equipped with \( \mathcal{O}_i : \mathcal{X}(j) \times \mathcal{X}(k) \to \mathcal{X}(j + k - 1), \)
\( j \in \mathbb{Z}_+, k \in \mathbb{N}, 1 \leq i \leq k, \) actions of \( S_n \) on \( \mathcal{X}(n), n \in \mathbb{Z}_+, \) respectively, and \( I \in \mathcal{X}(1) \)

satisfying the conditions (1)-(3) above with \( K(n), n \in \mathbb{N}, \) replaced by \( \mathcal{X}(n), i_\infty \)

by \( \mathcal{O}_i, \) is called an operad [M1]. If the operations \( \mathcal{O}_i \) are only partial and conditions

(1)-(3) are satisfied when the operations in the equations in (1)-(3) exist, it is called a partial operad [M2] [HL2] [HL3]. Thus we see that \( K \) is a partial operad. We can also give a topological structure and a complex analytic structure to \( K \) such that the sewing operations \( i_\infty \) are continuous and complex analytic.

We shall define a (geometric) vertex operator algebra to be a “linear projective representation” of this partial operad satisfying some additional conditions. In the representation theory of groups, a linear projective representation of a group is a linear representation of a central extension of the group. For \( K, \) we also have certain extensions which are analogues of central extensions of groups. These extensions are constructed using determinant lines over spheres with analytically parametrized boundary.

We describe briefly Segal’s work on determinant lines over Riemann surfaces with analytically parametrized boundary here. For details, see [S]. Let \( \Sigma \) be a compact Riemann surface with analytically parametrized and oriented boundary components. We have the Cauchy-Riemann operator \( \bar{\partial} \) from the space \( \Omega^0(\Sigma) \) of smooth functions on the surface to the space \( \Omega^{0,1}(\Sigma) \) of \( (0,1) \)-forms on the surface. The boundary of \( \Sigma \) can be decomposed as \( \partial \Sigma = \bigcup_{i=1}^k C_i^{\epsilon_i} \) where for any \( i, 1 \leq i \leq k, C_i^{\epsilon_i} \)

is a connected component of \( \partial \Sigma \) and thus is parametrized by an analytic map from the circle \( S^1 \) to \( C_i^{\epsilon_i} \) and where \( \epsilon_i = \pm \) indicates the orientation of the component. Any smooth function on \( C_i^{\epsilon_i} \) can be decomposed as the sum of two smooth functions, one of which, as a function on \( S^1, \) has a Fourier expansion of the form \( \sum_{n \geq 0} a_n e^{2\pi n \theta i} \)

(\( \theta \) is the usual parametrization of the circle by angles) and the other of which, as a function on \( S^1, \) has a Fourier expansion of the form \( \sum_{n < 0} a_n e^{2\pi n \theta i}. \) If \( \epsilon_i = + \)

(\( \epsilon_i = - \)), that is, this component is positively (negatively) oriented, we denote by \( \Omega_+^0(C_i^{\epsilon_i}) \) the space of all smooth functions on \( C_i^{\epsilon_i} \) which as functions on \( S^1 \) have
Fourier expansions of the form \( \sum_{n \geq 0} a_n e^{2\pi n \theta_i} \) and by \( \Omega^0_\pm (\partial \Sigma) \) the space of smooth functions on \( C^\infty \) which as functions on \( S^1 \) have Fourier expansions of the form \( \sum_{n < 0} a_n e^{2\pi n \theta_i} \). Thus the space \( \Omega^0_\pm (\partial \Sigma) \) of all smooth functions on \( \partial \Sigma \) can be decomposed as \( \bigoplus_{i=1}^k (\Omega^0_+ (C^\infty_i) \oplus \Omega^0_- (C^\infty_i)) \). Following Segal’s notation, let

\[
\Omega^0_+ (\partial \Sigma) = \bigoplus_{i=1}^k \Omega^0_{\pm, i} (C^\infty_i) \subset \Omega^0 (\partial \Sigma).
\]

(Note that in our notation, it is better to denote this space by \( \Omega^0_0 (\partial \Sigma) \). We denote it by \( \Omega^0_0 (\partial \Sigma) \) so that it agrees with Segal’s notation.) Let \( pr \) be the composition of the restriction from \( \Omega^0 (\Sigma) \) to \( \Omega^0 (\partial \Sigma) \) and the projection from \( \Omega^0 (\partial \Sigma) \) to \( \Omega^0_+ (\partial \Sigma) \). We have an operator

\[
\overline{\partial} \oplus pr : \Omega^0 (\Sigma) \to \Omega^{0,1} (\Sigma) \oplus \Omega^0_+ (\partial \Sigma).
\]

Using the theory of elliptic boundary problems on manifolds with boundaries (see, for example, [Hö]), we can show that \( \overline{\partial} \oplus pr \) can be extended to Fredholm operators from suitable Sobolev spaces on \( \Sigma \) to direct sums of closed subspaces of suitable Sobolev spaces on \( \Sigma \) and closed subspaces of suitable Sobolev spaces on \( \partial \Sigma \). In addition, the kernels of these extensions are equal to the kernel of \( \overline{\partial} \oplus pr \) and the orthogonal complements of the images of these extensions are in \( \Omega^{0,1} (\Sigma) \oplus \Omega^0_+ (\partial \Sigma) \). Thus we can regard the kernel and cokernel of \( \overline{\partial} \oplus pr \) as the kernels and cokernels of its extensions. Since these extensions are Fredholm, the kernel and cokernel of \( \overline{\partial} \oplus pr \) are finite-dimensional. The determinant line over \( \Sigma \) is defined as

\[
\det_{\Sigma} = \det (\ker (\overline{\partial} \oplus pr))^* \otimes \det \text{coker} (\overline{\partial} \oplus pr)
\]

where \( \det (\ker (\overline{\partial} \oplus pr))^* \) and \( \det \text{coker} (\overline{\partial} \oplus pr) \) are the highest nonzero exterior powers of \( (\ker (\overline{\partial} \oplus pr))^* \) and \( \text{coker} (\overline{\partial} \oplus pr) \), respectively. The main property of determinant lines over Riemann surfaces with analytically parametrized and oriented boundary components is that if we sew two such Riemann surfaces, \( \Sigma_1 \) and \( \Sigma_2 \), by identifying certain boundary components on \( \Sigma_1 \) to certain boundary components with opposite orientations on \( \Sigma_2 \) using the given analytic parametrizations to obtain another such, denoted by \( \Sigma_1 \sqcup \Sigma_2 \), then there exists a canonical isomorphism

\[
\ell_{\Sigma_1, \Sigma_2} : \det_{\Sigma_1} \otimes \det_{\Sigma_2} \to \det_{\Sigma_1 \sqcup \Sigma_2}.
\]

These determinant lines give a holomorphic line bundle over the moduli space of Riemann surfaces with oriented and analytically parametrized boundaries, and there is a canonical connection on this line bundle. See [S] for more details.

Now we want to use Segal’s work described above to define the determinant line for an element \( Q \) of \( K \). We need to find a sphere with analytically parametrized and oriented boundary \( \Sigma_Q \) determined uniquely by \( Q \). For any \( Q \in K \), there is a unique sphere with punctures and local coordinates in \( Q \) such that its underlying sphere is \( \mathbb{C} \cup \{\infty\} \), the negatively oriented puncture is \( \infty \), the last positively oriented puncture
is 0, the value at ∞ of the derivative of the local coordinate map at ∞ is 1 and all the local coordinate neighborhoods at the punctures are the preimages under the local coordinate maps of the maximal open disks (possibly with infinite radius) centered at 0 on which the inverses of local coordinate maps have well-defined analytic extensions. For any positive real number \( r \) and any puncture, consider the closed disk of radius equal to \( r \) times the minimum of 1 and half of the radius of the maximal disk above the puncture. (To avoid closed disks with infinite radius, we choose the minimum of 1 and half of the radius of the maximal disk instead of half of the radius of the maximal disk.) For a fixed \( r \), a closed disk above is called a \textit{closed disk associated to \( r \)}. Let \( X \) be the set of all positive real numbers such that if \( r \in X \), then at any puncture the closed disk associated to \( r \) is contained in the maximal open disk above and preimages under local coordinate maps of closed disks associated to \( r \) at different punctures do not intersect each other. Let \( r_0 = \text{sup} X \) and \( r_1 = \text{min}(1, \frac{r_0}{2}) \). (To make sure that \( r_1 \) is not \( \infty \), we define \( r_1 \) to be \( \min(1, \frac{r_0}{2}) \) instead of \( \frac{r_0}{2} \).) We obtain a Riemann surface with oriented and analytically parametrized boundary components \( \Sigma_Q \) by cutting the preimages of the closed disks associated to \( r_1 \) and giving its boundary components the obvious orientations and analytic parametrizations (by first mapping the unit circle to the circle with radius \( r_1 \)). We define

\[
\text{Det}_Q = \text{Det}_{\Sigma_Q}. \quad (3.9)
\]

We consider annuli on the complex plane with two circles centered at 0 as boundaries. They can be degenerate in the sense that the two boundary circles are the same. With the obvious orientations of the boundary circles and with multiplications by the radii of the boundary circles as analytic boundary parametrizations, these annuli become Riemann surfaces with oriented and analytically parametrized boundary components. If the inner circle of such an annulus is the unit circle, we call it a \textit{canonical annulus with oriented and analytically parametrized boundary components}. For \( m, n \in \mathbb{N} \), \( Q_1 \in K(m) \) and \( Q_2 \in K(n) \) such that \( Q_1 \subseteq Q_2 \), we can find unique Riemann surfaces with oriented and analytically parametrized boundary components \( A, B, C, D \) and \( E \) in which \( A, B, C, D \) and \( E \) are not connected and are disjoint unions of canonical annuli with oriented and analytically parametrized boundary components, such that \((A \otimes_{Q_1} \otimes B) \otimes (\otimes_{Q_2} \otimes C)\) is conformally equivalent to \((D \otimes_{Q_1} \otimes E) \otimes (\otimes_{Q_2} \otimes F)\). So we have a canonical isomorphism from \( \text{Det}_{(A \otimes_{Q_1} \otimes B) \otimes (\otimes_{Q_2} \otimes C)} \) to \( \text{Det}_{(D \otimes_{Q_1} \otimes E) \otimes (\otimes_{Q_2} \otimes F)} \). It can be shown easily that \( \text{Det}_A, \text{Det}_B, \text{Det}_C, \text{Det}_D \) and \( \text{Det}_E \) are canonically isomorphic to \( \mathbb{C} \). Thus we obtain canonical isomorphisms from \( \text{Det}_{\Sigma_{Q_1}} \otimes \text{Det}_{\Sigma_{Q_2}} \) to \( \text{Det}_A \otimes \text{Det}_{\Sigma_{Q_1}} \otimes \text{Det}_C \) and from \( \text{Det}_B \otimes \text{Det}_{\Sigma_{Q_1}} \otimes \text{Det}_C \). Composing in the obvious order the three canonical isomorphisms above with

\[
\ell(A \otimes_{Q_1} \otimes B) \otimes (\otimes_{Q_2} \otimes C) = \ell(A \otimes_{Q_1} \otimes B \otimes 1 \otimes 1 \otimes 1) \circ (\ell_A \otimes_{Q_1} \otimes 1 \otimes 1 \otimes 1).
\]
we obtain a canonical isomorphism
\[ \ell'_{Q_1,Q_2} : \text{Det}_{Q_1} \otimes \text{Det}_{Q_2} \to \text{Det}_{Q_1 \otimes \text{Det}_{Q_2}}. \]  

Let
\[ \tilde{K}(n) = \bigcup_{Q \in K(n)} \text{Det}_Q, \quad n \in \mathbb{N}, \]  
\[ \tilde{K} = \{ \tilde{K}(n) \}_{n \in \mathbb{N}}. \]  

Then \( \tilde{K}(n), n \in \mathbb{N}, \) are holomorphic line bundles (in a suitable sense) over \( K(n). \) There are also operations in \( \tilde{K} \) obtained from the sewing operations in \( K \) and the canonical isomorphisms for determinant lines defined as follows: Let \( m, n \in \mathbb{N}, i \) an integer satisfying \( 1 \leq i \leq m, Q_1 \in K(m), Q_2 \in K(n), \tilde{Q}_1 \in \text{Det}_{Q_1} \subset \tilde{K}(m) \) and \( \tilde{Q}_2 \in \text{Det}_{Q_2} \subset \tilde{K}(n), \) such that \( Q_1 \otimes \text{Det}_{Q_2} \) exists. We define
\[ \tilde{Q}_1 \otimes \tilde{Q}_2 = \ell'_{Q_1,Q_2} (\tilde{Q}_1 \otimes \tilde{Q}_2) \in \text{Det}_{Q_1 \otimes \text{Det}_{Q_2}} \subset \tilde{K}(m + n - 1). \]  

Thus we obtain a partial operation \( \otimes : \tilde{K}(m) \times \tilde{K}(n) \to \tilde{K}(m + n - 1) \) for any \( m, n \in \mathbb{N} \) and any integer \( i \) satisfying \( 1 \leq i \leq m. \) Note that the definition of determinant line over an element \( Q \in K(n) \) for any \( n \in \mathbb{N} \) does not use the ordering of the positively oriented punctures of \( Q. \) Thus for any \( \sigma \in S_n, \text{Det}_Q \) is canonically isomorphic to \( \text{Det}_{\sigma(Q)}. \) We denote this canonical isomorphism by \( \varphi^\sigma_Q. \) For any \( \tilde{Q} \in \text{Det}_Q \subset \tilde{K}(n), \) we define
\[ \sigma(\tilde{Q}) = \varphi^\sigma_Q (\tilde{Q}) \in \text{Det}_{\sigma(Q)} \subset \tilde{K}(n). \]  

We obtain an action of \( S_n \) on \( \tilde{K}(n). \) Let \( \tilde{I} \) be the unique element of \( \text{Det}_I \) satisfying \( \ell'_{I,I} (\tilde{I} \otimes \tilde{I}) = \tilde{I}. \) Then the sequence \( \tilde{K} \) together with the operations
\[ \otimes : \tilde{K}(m) \times \tilde{K}(n) \to \tilde{K}(m + n - 1), \]  
\( m, n \in \mathbb{N}, 1 \leq i \leq m, \) the actions of the symmetric groups and \( \tilde{I} \) is a partial operad. Also the operations \( \otimes, m, n \in \mathbb{N}, 1 \leq i \leq m, \) are all continuous and analytic with respect to the topological and analytic structures on the holomorphic line bundles \( \tilde{K}(n) \) over \( K(n), n \in \mathbb{N}. \)

For any \( n \in \mathbb{N}, \) there is a canonical connection on the determinant line bundle \( \tilde{K}(n) \) induced from the canonical connection on the determinant line bundle over the moduli space of Riemann surfaces with oriented and analytic parametrized boundaries. Using this connection, we can prove that the determinant line bundle \( \tilde{K}(n) \) is trivial. Thus for any complex number \( c, \) a \( c \)-th power of determinant line bundle \( \tilde{K}(n) \) is well defined. Note that a \( c \)-th power of \( \tilde{K}(n) \) is the line bundle whose fibers are the same as those of \( \tilde{K}(n) \) and whose transition functions are equal to certain branches of the \( c \)-th powers of the transition functions of \( \tilde{K}(n). \) The existence of a \( c \)-power of \( \tilde{K}(n) \) means that we can choose the branches of the \( c \)-th powers of the transition functions of \( \tilde{K}(n) \) consistently so that they also give a holomorphic line bundle, a \( c \)-th power...
of $\tilde{K}(n)$. So we see that because $\tilde{K}(n)$ is trivial, there is only one $c$-th power of $\tilde{K}(n)$ and it is in fact canonically isomorphic to $\tilde{K}(n)$. We denote the $c$-th power of $\tilde{K}(n)$ by $\tilde{K}^c(n)$. Since, as a line bundle over $K(n)$, $\tilde{K}^c(n)$ is canonically isomorphic to $\tilde{K}(n)$, we shall not distinguish between the elements of $\tilde{K}(n)$ and the elements of $\tilde{K}^c(n)$. In particular, for any element $\tilde{Q}$ of $\tilde{K}^c(n)$ there is $Q \in K(n)$ such that $\tilde{Q}$ is in $\text{Det}_Q$. The difference between $\tilde{K}^c$ and $\tilde{K}$ is that the canonical isomorphisms for them are different. We can prove that we can choose values of $\ell_{Q_1,Q_2}$ and $\varphi_Q^\sigma$ raised to the complex power $c$ (denoted by $(\ell_{Q_1,Q_2})^c$ and $(\varphi_Q^\sigma)^c$, respectively) consistently for $m,n \in \mathbb{N}$, $1 \leq i \leq m$, $Q_1 \in K(m)$, $Q_2 \in K(n)$ and $\sigma \in S_n$, such that $\tilde{K}^c = \{\tilde{K}^c(n)\}_{n \in \mathbb{N}}$ becomes a partial operad; the operations $\cdot \otimes$ are defined in the same way as those for $\cdot \otimes$ except that $\ell_{Q_1,Q_2}$ is replaced by $(\ell_{Q_1,Q_2})^c$, the actions of the symmetric groups are defined using $(\varphi_Q^\sigma)^c$ and the identity element is $\tilde{I} \in \tilde{K}^c(1)$.

The canonical connection on $\tilde{K}(n)$ gives a canonical connection on $\tilde{K}^c(n)$. Beginning with $\tilde{I}$, we obtain a section $\psi_1$ of $\tilde{K}^c(1)$ by parallel transport (this section is in fact not continuous when $c \neq 0$). Let $J \in K(0)$ be the conformal equivalence class containing the sphere $\mathbb{C} \cup \{\infty\}$ with the negatively oriented puncture $\infty$ and the standard local coordinate $w \to w^{-1}$ vanishing at $\infty$ and let $\tilde{J}$ be any fixed element of $\text{Det}_J$. Then beginning with $\tilde{J}$, we obtain a section $\psi_0$ of $\tilde{K}^c(0)$ by parallel transport. Let $P(1) \in K(2)$ be the conformal equivalence class containing the sphere $\mathbb{C} \cup \{\infty\}$ with the negatively oriented puncture $\infty$, the positively oriented punctures $1$ and $0$, the standard local coordinate $w \to w^{-1}$ vanishing at $\infty$, the standard local coordinate $w \to w^{-1}$ vanishing at $1$ and the standard local coordinate $w \to w$ vanishing at $0$. Let $\tilde{P}(1)$ be the unique element of $\text{Det}_{P(1)}$ such that $(\ell_{P(1),\tilde{J}})^c(\tilde{P}(1) \otimes \tilde{J}) = \tilde{I}$. Beginning with $\tilde{P}(1) \in \tilde{K}^c(2)$ we obtain a section $\psi_2$ of $\tilde{K}^c(2)$ by parallel transport. Since $K$ is generated by $K(0)$, $K(1)$ and $K(2)$ (which means that any element in $K(n)$ for any $n \in \mathbb{N}$ can be obtained by sewing elements in $K(0)$, $K(1)$ and $K(2)$), we obtain sections $\psi_n$ of $\tilde{K}^c(n)$, $n \in \mathbb{N}$. It can be shown that $\psi_n$, $n \in \mathbb{N}$, are well-defined. Then we have \{\psi_n\}_{n \in \mathbb{N}} which is a section of $\tilde{K}^c$.

To define a “linear representation” of $\tilde{K}^c$, we first have to construct a partial operad from a vector space. Given a $\mathbb{Z}$-graded vector space $V = \text{Hom}(V^n, V)$, such that $\text{dim}V(n) < \infty$, we can construct a partial operad in the following way (see [HL2], [HL3]): Let

\begin{align}
\mathcal{H}_V(n) &= \text{Hom}(V^n, V), \\
\mathcal{H}_V &= \{\mathcal{H}_V(n)\}_{n=1}^\infty
\end{align}

where $V = \text{Hom}(V^n, V)$. Let $P_n$, $n \in \mathbb{Z}$, be the projection from $V$ to $V(n)$. For $\ell \in \mathcal{H}_V(m)$, $g \in \mathcal{H}_V(n)$ and $0 \leq i \leq m$, if for any $v' \in V'$, $v_1, \ldots, v_{m+n-1} \in V$ the series

$$
\sum_{n \in \mathbb{Z}} \langle v', f(v_1, \ldots, v_{i-1}, P_n(g(v_i, \ldots, v_{i+n-1})), v_{i+n}, \ldots, v_{m+n-1}) \rangle
$$

(3.17)
where \( \langle \cdot, \cdot \rangle \) denotes the pairing between \( V' \) and \( \overline{\nabla} \) converges, we say that the contraction \( f \circ \ast_0 g \) exists and we define the contraction \( f \circ \ast_0 g \in \mathcal{H}_V(m + n - 1) \) using the values of these series. Note that contractions are partial operations. The permutation group \( S_n \) also acts on \( \mathcal{H}_V(n) \) in the obvious way. We also have the inclusion map \( I_V \in \mathcal{H}_V(1) = \text{Hom}(V, \overline{\nabla}) \). The sequence \( \mathcal{H}_V \) together with the contractions, the actions of the symmetric groups and the inclusion map \( I_V \), is a partial operad, called the endomorphism partial operad of \( V \).

Roughly speaking, a “geometric vertex operator algebra” (or a “vertex associative algebra”) is a \( \mathbb{Z} \)-graded vector space \( V \) equipped with a “homomorphism” from the partial operad \( \tilde{K}^c \) to the partial operad \( \mathcal{H}_V \) satisfying some additional natural axioms. Precisely, we have the following:

**Definition 3.1.** A geometric vertex operator algebra of central charge \( c \) is a \( \mathbb{Z} \)-graded vector space \( V \) and a map \( \Phi : \tilde{K}^c \to \mathcal{H}_V \) such that \( \Phi(\tilde{K}^c(n)) \subset \mathcal{H}_V(n) \) satisfying:

1. The positive energy axiom: \( V_{(n)} = 0 \) for \( n \) sufficiently small.
2. The grading axiom: Let \( Q(a) = (0, (a, 0)) \in H \times (\mathbb{C}^x \times H) = K(1) \) (the conformal equivalence class containing the sphere \( \mathbb{C} \cup \{ \infty \} \) with the negatively oriented puncture \( \infty \), the positively oriented puncture 0, the standard local coordinate \( w \to w^{-1} \) vanishing at \( \infty \) and the local coordinate \( w \to aw \) vanishing at 0). Then for any \( n \in \mathbb{Z}, v \in V_{(n)}, v' \in V' \),

\[
\langle v', \Phi(\psi_1(Q(a)))(v) \rangle_V = a^{-n} \langle \cdot, \cdot \rangle_{V_{(n)}}
\]

where \( \langle \cdot, \cdot \rangle_n \) is the pairing between \( V' \) and \( V_{(n)} \) induced from the pairing \( \langle \cdot, \cdot \rangle_V \) between \( V' \) and \( \overline{\nabla} \).

3. The permutation axiom: For any \( n \in \mathbb{N}, \sigma \in S_n \) and \( \bar{Q} \in \tilde{K}^c(n) \),

\[
\Phi(\sigma(\bar{Q})) = \sigma(\Phi(\bar{Q})).
\]

4. The analyticity axiom: For any \( n \in \mathbb{N} \), let

\[
\nu_n = \Phi \circ \psi_n : K(n) \to \mathcal{H}_V(n).
\]

Then for any \( v' \in V', v_1, \ldots, v_n \in V, \langle v', \nu_n(\cdot)(v_1 \otimes \cdots \otimes v_n) \rangle \) as a function of

\[
(z_1, \ldots, z_{n-1}; A^{(0)}, (a_0^{(1)}, A^{(1)}), \ldots, (a_0^{(n)}, A^{(n)})) \in K(n) = M^{n-1} \times H \times (\mathbb{C}^x \times H)^n
\]

is meromorphic in \( z_1, \ldots, z_{n-1} \) with \( z_i = 0 \) and \( z_i = z_j, i, j = 1, \ldots, n - 1, i \neq j \), as the only possible poles, and is a Laurent polynomial in \( a_0^{(1)}, \ldots, a_0^{(n)} \) and is a polynomial in the components of \( A^{(0)}, \ldots, A^{(n)} \). In addition, for fixed \( i, j, 1 \leq i < j \leq n, \) and \( v_i, v_j \in V \) there is an upper bound, independent of \( v_k, k \neq i, j \), for the order of the pole \( z_i - z_j \) of the function \( \langle v', \nu_n(\cdot)(v_1 \otimes \cdots \otimes v_i \otimes \cdots \otimes v_j \otimes \cdots \otimes v_n) \rangle \).
(5) The sewing axiom: For any \( m, n \in \mathbb{N} \), \( \tilde{Q}_1 \in \text{Det}_{Q_1} \subset \tilde{K}^c(m) \) and \( \tilde{Q}_2 \in \text{Det}_{Q_1} \subset \tilde{K}^c(n) \) such that \( Q_1 \mathrel{\curlywedge}^0 Q_2 \) exists, \( \Phi(\tilde{Q}_1) \mathrel{\ast^0} \Phi(\tilde{Q}_2) \) also exists and
\[
\Phi(\tilde{Q}_1; \mathrel{\curlywedge}^0 \tilde{Q}_2) = \Phi(\tilde{Q}_1) \mathrel{\ast^0} \Phi(\tilde{Q}_2).
\] (3.21)

The definition of homomorphism from one geometric vertex operator algebra to another of the same rank is clear. The following theorem (see [Hu1]–[Hu4] [Hu9]) establishes the equivalence between vertex operator algebras and geometric vertex operator algebras:

**Theorem 3.1.** The category of geometric vertex operator algebras of rank \( c \) is isomorphic to the category of vertex operator algebras of rank \( c \).

The map \( \nu \) in the definition above can also be constructed algebraically (see [Hu1] and [Hu9]).

4. VERTEX OPERATOR ALGEBRAS AND CONFORMAL FIELD THEORIES

The rapidly-evolving theory of vertex operator algebras has been starting to show its power in the study of many problems related to conformal field theories. It is expected that in the future this theory will play a more important role in the study of conformal field theories and related mathematical problems.

Basically, there are two approaches to conformal field theories. One is the geometric approach. In physics, many models of conformal field theories are studied using the path integral method. Starting from the work of Friedan and Shenker [FS], physicists have realized the importance of the moduli space of Riemann surfaces with punctures in the study of conformal field theories. The basic mathematical work in the geometric approach is Segal’s definition of conformal field theory using Riemann surfaces with oriented and analytically parametrized boundary components [S]. Motivated by the operator formalism for the theory of free bosons and free fermions, one closely related formulation of conformal field theories is given by Vafa [Va] using Riemann surfaces with punctures and local coordinates vanishing at these punctures, on a physical level of rigor. The geometric approach has the advantage that it gives conceptually satisfactory definitions and it also allows one to derive many important results using geometric intuition. But the main difficulty that the geometric approach encountered is that it is very difficult to construct nontrivial examples satisfying all these geometric axioms and thus also difficult to discover subtle structures that a conformal field theory might have. On the other hand, beginning with the seminal work of Belavin, Polyakov and Zamolodchikov [BPZ] in physics and the works of Borcherds [B], Frenkel, Lepowski and Meurman [FLM2] in mathematics, another approach, the algebraic one, provides a practical way for both physicists and mathematicians to construct concrete examples of conformal field theories, at least at genus zero and genus one. There are already many examples of conformal field theories (in the algebraic formulation) constructed from Lie algebras, lattices, Jordan algebras,
\(\mathcal{W}\)-algebras (certain associative algebras similar to the universal enveloping algebra of a Lie algebra). There are also algebraic methods, for example, methods to construct orbifold theories and coset models, which give more examples from known ones. But the algebraic approach has the disadvantage that it mostly constructs and studies only the genus-zero and genus-one theory. Also the axioms in the algebraic formulations may at first seem unfamiliar or complicated (although they are indeed completely canonical). It is therefore necessary and important to establish rigorously the relationship between the algebraic and geometric approaches. One of the main ingredients in a conformal field theory is its “chiral algebra,” which is a vertex operator algebra. The geometric interpretation of vertex operator algebras described in the preceding section can be viewed as a crucial step of the project of establishing the equivalence between the two approaches and thus obtaining examples satisfying the geometric axioms from the known examples satisfying the algebraic axioms. Another step in this direction is Zhu’s work [Z] in which he constructed certain genus-one correlation functions from a vertex operator algebra and its irreducible modules, assuming that the vertex operator algebra satisfies certain conditions.

Let me end this exposition with the following picture describing the program of studying conformal field theories and related mathematical problems using the representation theory of vertex operator algebras:

Elementary mathematical data (lattices, Lie algebras, Jordan algebras, \(\mathcal{W}\)-algebras, etc.)
\[\downarrow\]
Vertex operator algebras, modules, intertwining operators
\[\downarrow\]
Modular functors and conformal field theories (in the sense of Segal)
\[\downarrow\]
Consequences (Verlinde formulas, modular tensor categories, knot invariants and three-manifold invariants, monstrous moonshine, etc.)
