Autophagy is a highly conserved degradative process that conveys dysfunctional proteins, lipids, and organelles to lysosomes for degradation. The post-mitotic nature, complex and highly polarized morphology, and high degree of specialization of neurons make an efficient autophagy essential for their homeostasis and survival. Dysfunctional autophagy occurs in aging and neurodegenerative diseases, and autophagy at synaptic sites seems to play a crucial role in neurodegeneration. Moreover, a role of autophagy is emerging for neural development, synaptogenesis, and the establishment of a correct connectivity. Thus, it is not surprising that defective autophagy has been demonstrated in a spectrum of neurodevelopmental disorders, often associated with early-onset epilepsy. Here, we discuss the multiple roles of autophagy in neurons and the recent experimental evidence linking neurodevelopmental disorders with epilepsy to genes coding for autophagic/lysosomal system-related proteins and envisage possible pathophysiological mechanisms ranging from synaptic dysfunction to neuronal death.

Keywords: epilepsy, autophagy, lysosome, neuron development, synapse

INTRODUCTION

Macroautophagy (henceforth autophagy) is a highly conserved cellular process that tackles dysfunctional proteins, lipids, and organelles to lysosomes for degradation. Substrates are initially isolated by a double membrane, the phagophore, which subsequently elongates and surrounds the substrates with a membranous structure, the autophagosome (AP; Dikic and Elazar, 2018). APs are transient organelles destined to fuse with the lysosome for the degradation of their contents. Autophagy is virtually active in all cell types to ensure homeostasis and has been implicated in protein and organelle quality control, development and differentiation, aging, and immunity. Autophagy is modulated by nutrients and growth factors and levels of AMP/ATP sensed by mammalian target of rapamycin complex1 (mTORC1) and AMP-dependent protein kinase (AMPK), respectively (Menzies et al., 2017). A scheme of the autophagy pathway is reported in Figure 1.
Dysfunctional autophagy has been associated with several pathologies and most neurodegenerative diseases. Neurons appear to be particularly dependent on autophagy since their post-mitotic nature makes them highly sensitive to the accumulation of toxic proteins and damaged organelles. The complex and polarized neuronal architecture poses specific challenges for an efficient cargo recycling. In neurons, APs are preferentially formed at synaptic terminals, and are transported to the cell soma, where they fuse to lysosomes for degradation. Here, we review the physiological role of autophagy in neurons and discuss recent experimental evidence linking neurodevelopmental disorders with epilepsy to genes of the autophagy/lysosomal systems (Table 1).

### Autophagy and Neurodegeneration

The central nervous system (CNS) requires autophagy to maintain its homeostasis. Since the ubiquitous deletion of core autophagy genes is lethal at the embryonic or perinatal stages,
## TABLE 1 | List autophagy/lysosomal genes involved in neurodevelopmental disorders with epilepsy.

| Disorder | Gene | Inheritance | Molecular defect | Key clinical features | Clinical references |
|----------|------|-------------|------------------|-----------------------|---------------------|
| Tuberous sclerosis-1 (OMIM # 191100) | **TSC1** | AD | Autophagy induction | • DD/ID • Epilepsy • Hamartomas in multiple organ systems • Renal failure | Lipton and Sahin (2014) |
| Tuberous sclerosis-2 (OMIM # 613254) | **TSC2** | AD | Autophagy induction | • DD/ID • Epilepsy • Hamartomas in multiple organ systems • Renal failure | Lipton and Sahin (2014) |
| TBCK encephaloneuropathy (OMIM #616900) | **TBCK** | AR | Autophagy induction | • DD/ID • Regression and cognitive decline • Neuronopathy • Epilepsy | Bhoj et al. (2016), Chong et al. (2016) and Ortiz-González et al. (2018) |
| Cortical atrophy/dysplasia and epilepsy | **VPS15** | AR | Autophagosome formation | • DD/ID • Cortical dysplasia • Ataxia • Hearing deficits • Epilepsy | Gstrein et al. (2018) |
| Beta-propeller protein-associated neurodegeneration (OMIM #300894) | **WDR45** | X-linked | Autophagosome elongation | • DD/ID • Encephalopathy with epilepsy • Rett-like stereotypies • Dystonia | Haack et al. (2012), Saitsu et al. (2013), Hayflick et al. (2018) and Carvill et al. (2018) |
| Vici syndrome (OMIM #242840) | **EPG5** | AR | Autophagosome–lysosome fusion | • Hypopigmentation (skin, hair, retina) • Agenesis of the corpus callosum • Epilepsy • Bilateral cataracts • Cardiomyopathy • Combined immunodeficiency • Microcephaly • DD • Failure to thrive | Dionisi Vici et al. (1988), Byrne et al. (2016) and Ebrahimi-Fakhari et al. (2016) |
| Spinocerebellar ataxia20 (OMIM #616354) | **SNX14** | AR | Autophagosome–lysosome fusion | • DD/ID • Ataxia • Coarse facial features • Epilepsy • Sensorineural hearing loss • Hepatosplenomegaly | Thomas et al. (2014) and Akizu et al. (2015) |
| Developmental encephalopathy with epilepsy | **ATP6V1A** | AD | v-ATPase function | • DD/ID • Encephalopathy with epilepsy • Quadriplegia | Van Damme et al. (2017) and Fassio et al. (2018) |
| X-linked ID, epilepsy and fulminant neurodegeneration | **ATP6AP2** | X-linked | v-ATPase function | • Cortical atrophy • DD/ID • Dysmorphic features • Early-onset neurodegeneration • Epilepsy | Hirose et al. (2019) |
| Ohtahara syndrome with progressive course | **DMXL2** | AR | v-ATPase function | • Profound DD • Cortical atrophy • Encephalopathy with epilepsy • Severe epilepsy • Failure to thrive • Dysmorphic features • Quadriplegia •Sensorineural hearing loss • Severe hypotonia | Esposito et al. (2019) |

Note: AD, autosomal dominant; AR, autosomal recessive; DD, developmental delay; ID, intellectual disability.

several nervous system-specific knockout mouse models have been developed to explore the roles of autophagy in CNS. Removal of Atg5 and Atg7 in neuronal precursor cells (NPCs) leads to the accumulation of cytoplasmic inclusion bodies, with neurodegeneration and progressive motor deficits, further pointing to autophagy as a key quality control system in neurons.
over their lifespan (Hara et al., 2006; Komatsu et al., 2006). In subsequent models, generated by targeting distinct genes of the core autophagic pathway (Fimia et al., 2007; Liang et al., 2010; Joo et al., 2016), similarly reduced survival and early-onset, progressive neurodegeneration occurred, although the underlying pathophysiological basis varied according to the specific gene targeted. Altogether these models emphasize autophagy as a major cellular process protecting against neurodegeneration, in line with the evidence that in human defective autophagy underlies the accumulation of protein aggregates in several neurodegenerative disorders (Rubinsztein et al., 2005; Kiriyama and Nochi, 2015).

**AUTOPHAGY AND NEUROGENESIS**

Balanced differentiation, proliferation, and cell death rates in the developing brain are essential for neurogenesis. The autophagy machinery interacts with developmental signals involved in cell fate decisions, including Wnt, Sonic hedgehog, TGFβ, and FGF (Kiyono et al., 2009; Gao et al., 2010; Jimenez-Sanchez et al., 2012; Zhang et al., 2012). Studies in animal models have disclosed the pivotal role of autophagy in neuronal proliferation and in sustaining the post-natal pool of NPCs. Loss of Ambra1, a Beclin1 activator, resulted in severe defects of the neural tube development, ubiquitinated protein accumulation, unbalanced cell proliferation, and excessive apoptosis, as a consequence of autophagy impairment (Fimia et al., 2007). In this model, impairment of basal autophagy induced hyperproliferation as indirect consequence of misregulated recycling of transcriptional factors (Cecconi et al., 2007; Fimia et al., 2007). Notch signaling is a master regulator of neurogenesis and neuronal development (Bray, 2006; Ables et al., 2011). Autophagy regulates Notch degradation and defects in the autophagy machinery impact on NPC fate (Wu et al., 2016). Impairing AP formation by in utero knockdown of Atg5 harms β-Catenin stability, thus, leading to inhibited differentiation and increased proliferation of NPCs in the developing cortex (Lv et al., 2015). These in vivo findings suggest that a multi-level interaction between autophagy, cell proliferation, and cell death occurs during mammalian neural development. As reviewed elsewhere, an important role for autophagy in adult neurogenesis has also emerged (Dhaliwal et al., 2017; Menzies et al., 2017).

**AUTOPHAGY AND NEURONAL POLARITY**

Neurons have a uniquely polarized morphology characterized by extended and highly elaborated axonal and dendritic Arborizations, and neuronal homeostasis is critical for establishment and maintenance of their polarized structures (Lee et al., 2013; Maday, 2016). From the earlier phases of neurodevelopment, a highly efficient autophagy is required to allow membrane trafficking events, axonal guidance, and establishment of brain connectivity (Dragich et al., 2016). Axonal APs undergo robust retrograde motility toward the soma, driven by the active motor dynein. Moreover, mutations in autophagy genes cause pathological processes associated with long-range white matter defects.

While autophagy in axonal development and homeostasis has been extensively studied, recent findings have also pointed out the key role of autophagy in ciliogenesis. In neurons, cilia are involved in cortical patterning, neurogenesis, neuronal maturation, and cerebellar development (Lee and Gleeson, 2010). The autophagy impairment due to somatic-activating mutations in MTOR leads to abnormal accumulation of the OFD1 protein at centriolar satellites and disruption of neuronal ciliogenesis. Impaired ciliogenesis abrogates Wnt signaling, which is required for neuronal polarization, and underlies cortical dyslamination reported in patients (Park et al., 2018).

**AUTOPHAGY AND SYNAPTIC FUNCTION**

Autophagy not only regulates early neuronal development but also plays specific, multiple, and largely unexplored roles at synapses. As recently reviewed, dysfunctional autophagy at both pre- and post-synaptic sites leads to aging and neurodegeneration (Nikoletopoulou et al., 2015; Vijayan and Verstreken, 2017; Azarnia Tehran et al., 2018; Liang and Sigrist, 2018). Degradation of postsynaptic neurotransmitter receptors involves trafficking in autophagosomal structures (Rowland, 2006; Shehata et al., 2012, 2018; Hui et al., 2019). At dopaminergic presynaptic sites, autophagy shapes synapse ultrastructure and modulates neurotransmitter release, while at glutamatergic synapses mTOR-regulated autophagy promotes spine pruning during development (Hernandez et al., 2012; Tang et al., 2014). The presynaptic proteins endophilin and its partner synaptojanin, known to regulate synaptic vesicle (SV) endocytosis and recycling, turned out to positively regulate synaptic autophagy, suggesting a functional link between SV cycling and autophagy. Endophilin induces the membrane curvature that recruits Atg3 and Atg8 to initiate synaptic AP generation (Murdoch et al., 2016; Soukup et al., 2016). Synaptojanin promotes synaptic autophagy by removing Atg18 from preautophagosomal structures necessary for AP maturation (George et al., 2014; Vanhauwaert et al., 2017). Conversely, the active zone protein Bassoon has been proposed to inhibit autophagy (Okerlund et al., 2017). At presynaptic sites, a role for autophagy in the degradation of SV proteins has been suggested, and the small GTPase Rab26 was reported to cluster SVs and direct them to preautophagosomal structures for degradation (Binotti et al., 2015; Lüningschröer et al., 2017). In addition, endosomal microautophagy, a chaperone-mediated form of autophagy, which directly targets proteins to the endo-lysosomal system, has been described to degrade misfolded synaptic proteins and regulate neurotransmission at the Drosophila neuromuscular junction (Uytterhoeven et al., 2015). The biogenesis of APs occurs in nerve terminals (Katsumata et al., 2010; Shehata et al., 2012), and synaptic APs retrogradely transport endocytosed elements to the neuronal soma for signaling (Wang et al., 2015). Whether SV cycling and synaptic autophagy are reciprocally regulated and how they crosstalk with somatic autophagy is a matter of investigation. In a recent article, selective induction of autophagy at the presynaptic site has been shown to specifically target damaged proteins, thus...
maintaining synapse integrity and function (Hoffmann et al., 2019). The discovery that neuronal autophagy and formation of APs at synapses are activity dependent (Shehata et al., 2018) suggests that synaptic autophagy may be regulated by long-term synaptic plasticity underlying learning and memory formation. However, whether autophagy stimulates or suppresses memory processes and its relationship with nutrient signaling pathways is still controversial. Fasting has been shown to induce autophagy in the hypothalamus, but to inhibit it in the hippocampus and cerebral cortex, where memory formation and consolidation occur. BDNF-mediated suppression of autophagy is required for the growth factor effects on synaptic plasticity and memory enhancement both in vitro and in vivo (Nikoletopoulou et al., 2017). Glatigny and coworkers recently showed that, in hippocampal neurons, autophagy is induced by synaptic plasticity paradigms and necessary for novel memory formation (Glatigny et al., 2019). These recent data suggest that autophagy is involved in the regulation of synaptic strength and that its dysregulation may impact on the plasticity of the network and on the excitation/inhibition balance.

**AUTOPHAGY AND NEURODEVELOPMENTAL DISORDER WITH EPILEPSY**

In the last decade, several single-gene disorders of the autophagy pathway—defined as “congenital disorders of autophagy”—have been identified through next-generation sequencing. Genetic defects affect a range of functional steps from early phases of autophagy induction to autolysosome formation. The associated disorders, which are clinically heterogeneous, mainly affect the central and peripheral nervous systems, but often cause multi-systemic involvement (Ebrahim-Fakhari et al., 2016). Structural brain abnormalities, developmental delay, intellectual disability, severe epilepsy, and progressive impairment in relation to neurodegeneration are common features of this class of disorders. Members of the autophagy process involved in neurodevelopmental disorders with epilepsy are highlighted in Figure 1 and discussed below.

A direct link between autophagy and epileptogenesis was first supported by studies showing that rapamycin, an inhibitor of the mTOR pathway and a powerful autophagy inducer, strongly modulates seizures in several models (Giorgi et al., 2015). Germline and somatic mutations in genes of the mTOR pathway have been identified in patients with various epileptic disorders (Parrini et al., 2016), and a direct contribution of defective autophagy to neurodegeneration are common features of this class of disorders. Members of the autophagy process involved in neurodevelopmental disorders with epilepsy are highlighted in Figure 1 and discussed below.

Mutations in **TBCK** cause a neurodevelopmental syndrome with intellectual disability, coarse face, congenital hypotonia, leukoencephalopathy, progressive motor neuropathy, and seizures (Bhoj et al., 2016; Chong et al., 2016; Ortiz-González et al., 2018). As suggested by bioinformatic analysis, **TBCK** encodes a putative Rab GTPase-activating protein, although its function remains elusive. Loss-of-function mutations in **TBCK** lead to inhibition of mTORC1 and, thus, to uncontrolled autophagy induction in patient-derived fibroblasts (Bhoj et al., 2016; Ortiz-González et al., 2018). In this model, loss of TBCK results in increased number of APs accompanied by an augmented autophagic flux insensitive to pro-autophagic stimuli (Ortiz-González et al., 2018). Glycosylated proteins were not properly degraded in TBCK patients’ fibroblasts, and storage of lipofuscin was observed in patient’s neurons (Beck-Wödl et al., 2018; Ortiz-González et al., 2018), suggesting that disrupted autophagy leads to a storage disease phenotype (Teinert et al., 2020).

The signaling pathway adapting the autophagic response to nutrients and energy levels focuses on the phosphorylation of the ULK1 complex, a process which controls the recruitment of the VPS34/VPS15/Ambr1/Beclin1 complex to the phagophore and the formation of PI3P and downstream autophagy effectors through the binding of WD-repeat phosphoinositide-interacting (WIPI) proteins (Menzies et al., 2017; Figure 1). Gstrein et al. (2018) identified a recessive homozygous mutation in **VPS15** (L1224R) in a single patient with severe cortical atrophy and dysplasia, optic nerve atrophy, intellectual disability, spasticity, ataxia, muscle wasting, and seizures. The L1224R mutation leads to an accumulation of autophagy substrates in patient’s fibroblasts. In the same study, a forebrain-specific conditional Vps15 mouse model was developed revealing that loss of Vps15 resulted in severe cortical atrophy accompanied by autophagic impairment and progressive degeneration of the hippocampus and cortex (Gstrein et al., 2018).

Mutations in X-linked gene **WDR45**, encoding WIPI4, cause beta-propeller protein-associated neurodegeneration (BPAN; Haack et al., 2012; Saitsu et al., 2013). BPAN is a variant of neurodegeneration with brain iron accumulation spectrum (Haylick et al., 2018) and is characterized by a bi-phasic development. After an initial epileptic encephalopathy in the childhood, progressive neurodegeneration and Parkinsonism develop in adulthood (Carvill et al., 2018). Studies in WDR45 patients’ fibroblasts and neurons derived from their reprogramming showed that loss of WDR45 leads to higher levels of cell iron and oxidative stress, accompanied by mitochondrial abnormalities, autophagic impairment, and dysfunctional lysosomes (Seibler et al., 2018). In mice, deletion of Wdr45 in the brain results in axonal pathology and accumulation of autophagy substrates in neurons (Zhao et al., 2015).

Biallelic **EPG5** mutations in the Vici syndrome, together with recessive **SNX14** variants in cerebellar ataxia and intellectual disability syndrome, affect the late stages of autophagy. Vici syndrome is a severe progressive neurodevelopmental multisystem disorder featuring agenesis of the corpus callosum, bilateral cataracts, hypertrophic and/or dilated cardiomyopathy, combined immunodeficiency, and hypopigmentation (Dionisi
ATP6V1A has been recently shown to activate autophagy by Fassio et al., 2018. On the contrary, covalent targeting of phenotype result in loss of function and autophagy impairment in murine neurons. The mutations associated with the severe neurite development and synaptic contacts when expressed in patients' cells and impair neurite development and synaptic contacts when expressed in murine neurons. The mutations associated with the severe phenotype result in loss of function and autophagy impairment (Fassio et al., 2018). The EPG5 protein acts as a tethering factor that determines the fusion specificity of APs with late endosomes/lysosomes (Wang et al., 2016), and in vivo loss of EPG5 results in block of the autophagic pathway, progressive motor deficit, and neurodegeneration (Zhao et al., 2013). Bi-allelic mutations in SNX14 are the cause of autosomal-recessive childhood-onset spinocerebellar ataxia 20 (Thomas et al., 2014; Akizu et al., 2015). Patients showed progressive cerebellar neurodegeneration, developmental delay, intellectual disability, and seizures (Akizu et al., 2015). SNX14 encodes a protein, of the sorting nexin family and binds lysosomal membrane phosphatidylidyinositol residues, that is enriched in AP-containing cell fraction where it mediates lysosome–AP fusion (Mas et al., 2014). In SNX14 patient-derived neurons, lysosomal enlargement and autophagic dysfunction were reported. This phenotype was also observed in the Snx14-zebrafish model, where it leads to progressive Purkinje cell degeneration, suggesting that impaired autophagy finally results in neuronal cell death (Akizu et al., 2015). In cultured mouse neurons, loss of Snx14 decreases intrinsic excitability and impairs both excitatory and inhibitory synaptic transmission (Huang et al., 2014).

The vacuole H⁺-adenosine triphosphatases (v-ATPase) is a proton pump responsible for acidification of intracellular organelles and secretory granules that regulates several cellular processes such as protein trafficking, maturation, and degradation (Forgac, 2007). Acidification of lysosomes by v-ATPase is essential for autophagy progression, and inhibiting v-ATPase activity is a widely used treatment to mimic a block of autophagy. In neurons, v-ATPase is expressed by SVs and allows neurotransmitter loading and SV trafficking (Bodzęta et al., 2017). V-ATPase is a multimeric complex composed by a cytosolic domain (v₁), responsible for ATP hydrolysis, and a transmembrane domain (v₀), responsible for H⁺ transport. Recessive mutations in ATP6V1A, coding for the“A” subunit of the v₁ sub-complex, have been first described in patients with cutis laxa, dysmorphic features, and seizures in the context of a severe condition with premature lethality (Van Damme et al., 2017). Subsequently, we described de novo heterozygous mutations in ATP6V1A in four patients with developmental delay and epilepsy with variable of severity, ranging from mild intellectual disability and epilepsy to early-onset epileptic encephalopathies accompanied by myelination defects and brain atrophy. Pathogenic mutations affect lysosomal homeostasis in patients’ cells and impair neurite development and synaptic contacts when expressed in murine neurons. The mutations associated with the severe phenotype result in loss of function and autophagy impairment (Fassio et al., 2018). On the contrary, covalent targeting of ATP6V1A has been recently shown to activate autophagy by increasing v-ATPase catalytic activity and inhibiting mTORC1 activation (Chung et al., 2019).

A de novo deletion variant of the v-ATPase accessory protein ATP6AP2 has been found in a patient with neurodevelopmental disorder characterized by fulminant degeneration (Hirose et al., 2019). This patient exhibited mild facial dysmorphisms, early-onset intractable seizures, and spasticity. Sequential MRI scans documented progressive brain shrinkage with thin corpus callosum and hypomyelination. The authors, by employing both patient's iPSC-derived neural cells and murine knockout models, demonstrated that ATP6AP2 is a key regulator of v-ATPase function in the CNS, and that its loss results in lysosomal and autophagic defects. In these models, the loss of ATP6AP2 impairs stem cell self-renewal and neuronal survival with a strong dependence on the dosage of the transcripts.

In addition to ATP6AP2, v-ATPase assembly and activity relies on several parameters, including kinase activity, nutrient and stress levels, extra- and intra-cellular pH, and accessory proteins that interact with v₀ and v₁ components (McGuire et al., 2017). We recently demonstrated that DMXL2, a member of WD40 protein family known to regulate v-ATPase trafficking and activity (Yan et al., 2009; Einhorn et al., 2012; Tuttle et al., 2014), is mutated in children with severe developmental and epileptic encephalopathy, associating Ohtahara syndrome, and profound developmental delay with a progressive course leading to premature mortality. MRI scans in these patients showed thin corpus callosum, hypomyelination, and progressive brain shrinkage. Loss of DMXL2 protein in patients’ fibroblasts results in impaired autophagy, and modeling DMXL2 loss in murine neurons recapitulates defective autophagy and affects neurite development and synaptic connectivity (Esposito et al., 2019). While the complete loss of DmXL2 is embryonically lethal in mice (Tata et al., 2014; Gobé et al., 2019), heterozygous DmXL2 mice show macrocephaly and corpus callosum dysplasia, confirming the DMXL2 role in brain development (Kannan et al., 2017).

Altogether, these pieces of evidence support a primary role of autophagy dysregulation in epileptogenesis and suggest that severity of the clinical manifestations variably evolving in a neurodegenerative disorder might depend on different timing and specificity of molecular events underlying epilepsy and neurodegeneration. Defects altering early stages of neuronal development and, therefore, synaptic activity could underlie pro-epileptogenic changes in neuronal circuitries followed by progressive accumulation of autophagy substrates and consequent neuronal stress and degeneration. Our hypothesis is that the spectrum of phenotypes and clinical severities of the epileptic syndromes associated with mutations of autophagy genes primarily derive from an initial synaptic dysfunction, with structural and functional synaptic alterations that, depending on gene dosage and/or severity of the pathogenic mutations, may turn into neuronal damage with degeneration and death. Future work on disease murine models and/or patient-derived neurons needs to be performed to unravel the cellular and molecular mechanisms linking autophagy failure to brain hyperexcitability, seizures, and fulminant neurodegeneration and to evaluate the ability of autophagy inducers as novel therapeutic strategies for these intractable disorders.
