Abstract: We present a next-to-leading order calculation of Higgs boson production via gluon fusion interfaced to shower Monte Carlo programs, implemented according to the POWHEG method. A detailed comparison with MC@NLO and PYTHIA is carried out for several observables, for the Tevatron and LHC colliders. Comparisons with next-to-next-to-leading order results and with resummed ones are also presented.

Keywords: QCD, Monte Carlo, NLO Computations, Resummation, Collider Physics
1. Introduction

Gluon fusion is the dominant Higgs boson production mechanism both at the Tevatron and at the LHC. Radiative corrections to this process are known to be large [1, 2, 3], and it is thus important that shower generators that do include them are made available to the experimental collaborations. In fact, one such generator already exists, namely the MC@NLO implementation [4] of Higgs boson production.

In this work we present a next-to-leading order (NLO) calculation of Higgs boson production via gluon fusion, interfaced to shower Monte Carlo programs according to the POWHEG method. Unlike the MC@NLO implementation, our generator produces events with
positive (constant) weight, and, furthermore, is not tied to the \textsc{herwig} shower Monte Carlo program. It can be easily interfaced to any modern shower generator and, in fact, we show results of \textsc{powheg} interfaced to \textsc{herwig} \cite{5,6} and to \textsc{pythia} \cite{7}.

The \textsc{powheg} method was first suggested in ref. \cite{8}. In ref. \cite{9} a detailed general description of its application to collider processes was given. Until now, the \textsc{powheg} method has been applied to $ZZ$ pair hadroproduction \cite{10}, heavy-flavour production \cite{11}, $e^+e^-$-annihilation into hadrons \cite{12} and into top pairs \cite{13}, and Drell-Yan vector boson production \cite{14,15}. We have built our implementation of the Higgs boson production by following closely the formulae and results of ref. \cite{9}.

Much of our phenomenological section will be devoted to study the comparison of our result with that of \textsc{mc@nlo}. We find fair agreement between \textsc{mc@nlo} and \textsc{powheg} results, except for the $p_T$ distribution of the Higgs boson, and consequently of the hardest jet, in the high-$p_T$ region. In this region, the \textsc{powheg} distributions are generally harder. We have shown that this is due to next-to-next-to-leading order (NNLO) effects in the \textsc{powheg} formula for the differential cross section. We checked that these effects actually bring our result closer to the NNLO one \cite{16}. Other relevant discrepancies are found in the rapidity difference of the Higgs boson and the hardest jet. The dip produced by the \textsc{mc@nlo} program, found in previous implementations \cite{10,11,14}, is present also here. We remark that this seems to be a general feature of \textsc{mc@nlo}, since other calculations do not find effects of this kind \cite{17,18,19}.

The paper is organized as follows. In sec. 2 we describe how we performed the calculation for the Higgs boson cross section at the next-to-leading order. In sec. 3 we discuss the \textsc{powheg} implementation. In sec. 4 we show our results for several kinematic variables and compare them with the \textsc{mc@nlo} \cite{4} and \textsc{pythia 6.4} \cite{7} shower Monte Carlo programs. A comparison with next-to-next-to-leading order results, as well as with analytical resummed ones is also carried out. In sec. 5, we give our conclusions.

2. Description of the calculation

In this section we fix our kinematic notation, and give the Higgs boson production differential cross sections up to next-to-leading order in the strong coupling $\alpha_s$.

2.1 Kinematics

2.1.1 Born kinematics

The Born process has a single partonic contribution, $gg \to H$. Following the notation of ref. \cite{9}, we denote with $\bar{k}_\oplus$ and $\bar{k}_\ominus$ the incoming gluon momenta, aligned along the plus and minus direction of the $z$ axis, and by $\bar{k}_1$ the outgoing Higgs boson momentum. If $K_{\oplus}$ and $K_{\ominus}$ are the momenta of the incoming hadrons, then we have

$$\bar{k}_\oplus = \bar{x}_\oplus K_{\oplus},$$

where $\bar{x}_\oplus$ are the momentum fractions, and momentum conservation reads

$$\bar{k}_\oplus + \bar{k}_\ominus = \bar{k}_1.$$
We introduce the Higgs boson invariant mass squared and rapidity
\[ M^2 = \bar{k}_1^2, \quad Y = \frac{1}{2} \log \frac{\bar{k}_0^0 + \bar{k}_1^3}{\bar{k}_0^0 - \bar{k}_1^3}, \] (2.3)
so that the set of variables \( \Phi_1 \equiv \{ M^2, Y \} \) fully parametrizes the Born kinematics. From them, we can reconstruct the momentum fractions
\[ \bar{x}_\oplus = \sqrt{\frac{M^2}{S}} e^Y, \quad \bar{x}_\ominus = \sqrt{\frac{M^2}{S}} e^{-Y}, \] (2.4)
where \( S = (K_\oplus + K_\ominus)^2 \) is the squared center-of-mass energy of the hadronic collider. The Born phase space, in terms of these variables, can be written as
\[ d\Phi_1 = d\bar{x}_\oplus d\bar{x}_\ominus (2\pi)^4 \delta^4(\bar{k}_\oplus + \bar{k}_\ominus - \bar{k}_1) \frac{d^3k_1}{(2\pi)^3} \frac{1}{2\bar{k}_1^0} \delta(M^2 - m_H^2) dM^2 dY. \] (2.5)
We generate the Higgs boson virtuality according to a Breit-Wigner distribution, i.e. we make the replacement
\[ \delta(M^2 - m_H^2) \rightarrow \frac{1}{\pi} \frac{M^2 \Gamma_H/m_H}{(M^2 - m_H^2)^2 + (M^2 \Gamma_H/m_H)^2}. \] (2.6)
The decay of the Higgs boson is left to the shower Monte Carlo program, since, being the Higgs boson a scalar, no spin correlation can arise.

### 2.1.2 Real-emission kinematics
The real emission processes have an additional final-state parton, so that momentum conservation reads
\[ k_\oplus + k_\ominus = k_1 + k_2, \] (2.7)
where \( k_1 \) is the Higgs boson momentum and \( k_2 \) is the momentum of the additional final-state parton in the laboratory frame and
\[ k_\ominus = x_\ominus K_\ominus. \] (2.8)
Since we regularize the infrared divergences in the Frixione, Kunszt and Signer (FKS) subtraction scheme [20, 21], we introduce the appropriate set of radiation variables. In the partonic center-of-mass frame, the final-state parton has momentum
\[ k_2' = k_2^0 (1, \sin \theta \sin \phi, \sin \theta \cos \phi, \cos \theta), \] (2.9)
and we use the set \( \Phi_{\text{rad}} \equiv \{ \xi, y, \phi \} \) as radiation variables, where
\[ k_2'^0 = \frac{\sqrt{s}}{2} \xi, \quad y = \cos \theta, \] (2.10)
\[^{1}\text{In order to compare our result with other programs, we have also used slightly different forms of the Breit-Wigner distribution, that will be illustrated in due time.}\]
and

\[ s = (k_{\oplus} + k_{\ominus})^2 = \frac{M^2}{1 - \xi} \]  

(2.11)

is the partonic center-of-mass energy squared. Since there are no final-state coloured partons at the Born level, we have to deal with initial-state singularities only. The soft singularity is characterized by \( \xi \to 0 \), while the collinear limits (\( k_2 \) parallel to the \( \oplus \) or \( \ominus \) incoming directions) are characterized by \( y \to 1 \) and \( y \to -1 \) respectively.

### 2.1.3 Inverse construction

The set of variables \( \Phi_2 \equiv \{ M^2, Y, \xi, y, \phi \} \) fully specifies the real-emission kinematics. In fact, given these variables, we can reconstruct all the momenta. Using eq. (2.4), we can compute the underlying Born momentum fractions \( \bar{x}_{\oplus} \) and, following sec. 5 of ref [9], we have

\[
  x_{\oplus} = \frac{\bar{x}_{\oplus}}{\sqrt{1 - \xi}} \sqrt{\frac{2 - \xi(1 - y)}{2 - \xi(1 + y)}}, \quad x_{\ominus} = \frac{\bar{x}_{\ominus}}{\sqrt{1 - \xi}} \sqrt{\frac{2 - \xi(1 + y)}{2 - \xi(1 - y)}},
\]

(2.12)

with the kinematics constraints

\[ 0 \leq \xi \leq \xi_M(y), \]

(2.13)

where

\[
  \xi_M(y) = 1 - \max \left\{ \frac{2(1 + y) \bar{x}_{\oplus}^2}{\sqrt{(1 + \bar{x}_{\oplus}^2)^2(1 - y)^2 + 16 y \bar{x}_{\oplus}^2 + (1 - y)(1 - \bar{x}_{\oplus}^2)}}, \quad \frac{2(1 - y) \bar{x}_{\ominus}^2}{\sqrt{(1 + \bar{x}_{\ominus}^2)^2(1 + y)^2 - 16 y \bar{x}_{\ominus}^2 + (1 + y)(1 - \bar{x}_{\ominus}^2)}} \right\}.
\]

(2.14)

The momentum of the final-state parton in the partonic center-of-mass frame is given by eqs. (2.9) and (2.10). We then make a longitudinal boost \( B_L \) from the center-of-mass frame back to the laboratory frame, with boost velocity

\[ \beta = \frac{x_{\oplus} - x_{\ominus}}{x_{\oplus} + x_{\ominus}}, \]

(2.15)

to obtain \( k_2 \) from \( k'_2 \)

\[ k_2 = B_L k'_2. \]

(2.16)

From momentum conservation, we reconstruct the Higgs boson momentum

\[ k_1 = x_{\oplus} K_{\oplus} + x_{\ominus} K_{\ominus} - k_2. \]

(2.17)

Finally, the two-body phase space can be written in a factorized form in terms of the Born and radiation phase space

\[
  d\Phi_2 = dx_{\oplus} dx_{\ominus} (2\pi)^4 \delta^4(k_{\oplus} + k_{\ominus} - k_1 - k_2) \frac{d^3k_1}{(2\pi)^3} \frac{d^3k_2}{(2\pi)^3} = d\Phi_1 d\Phi_{\text{rad}},
\]

(2.18)

where

\[
  d\Phi_{\text{rad}} = \frac{M^2}{(4\pi)^3} \frac{\xi}{(1 - \xi)^2} d\xi dy d\phi.
\]

(2.19)
2.2 Cross sections

In order to apply the POWHEG method, we need the Born, real and virtual contributions to the differential cross section, i.e. the squared amplitudes, averaged over colours and helicities of the incoming partons, and multiplied by the appropriate flux factor.

2.2.1 Born contribution

At Born level, Higgs boson production via gluon fusion proceeds through the coupling of the Higgs boson to a heavy-quark loop. The squared matrix element for the lowest-order contribution, averaged over colours and helicities of the incoming gluons, and multiplied by the flux factor \( \frac{1}{2M^2} \), is given by

\[
B_{gg} = \frac{\alpha_s^2 G_F M^2}{\pi \sqrt{2}} \left| \frac{3}{2} \sum_Q \tau_Q \left[ 1 + (1 - \tau_Q) f(\tau_Q) \right] \right|^2,
\]

where \( \tau_Q = \frac{4m_Q^2}{M^2} \), and the sum runs over the heavy flavours with mass \( m_Q \) circulating in the loop. The function \( f \) is given by

\[
f(\tau_Q) = \begin{cases} 
\arcsin^2 \frac{1}{\sqrt{\tau_Q}} & \tau_Q \geq 1, \\
-\frac{1}{4} \left\{ \log \left( \frac{1 + \sqrt{(1 - \tau_Q)}}{1 - \sqrt{(1 - \tau_Q)}} \right) - i\pi \right\}^2 & \tau_Q < 1.
\end{cases}
\]

In our implementation we only retain the contribution coming from the top quark.

2.2.2 Virtual corrections

In the calculation of all NLO corrections, we have used an effective Lagrangian, where the heavy-quark degrees of freedom have been integrated out. This corresponds to take the \( m_Q \to \infty \) limit.

We have regularized the infrared divergences according to the conventional dimensional regularization method, i.e. we have set the space-time dimensions \( D = 4 - 2\epsilon \).

The finite soft-virtual term, obtained from the sum of the divergent virtual contributions and of the integral over the radiation variables of the counter-terms is given by (see eq. (2.99) of ref. [9])

\[
V_{gg} = \frac{\alpha_s}{2\pi} \left[ - \left( \frac{11}{3} C_A - \frac{4}{3} T_F n_f \right) \log \frac{\mu_F^2}{\mu_r^2} + \frac{11}{3} C_A + \frac{2\pi^2}{3} C_A \right] B_{gg}.
\]

In deriving this equation we have set \( \xi_c = 1 \). We indicate with \( \mu_r \) and \( \mu_F \) the renormalization and factorization scales, respectively.

2.2.3 Real corrections

At NLO, there are four subprocesses that contribute to Higgs boson production: \( gg \to Hg \), \( gq \to Hq \), \( qg \to Hq \) and \( q\bar{q} \to Hg \), where \( q \) runs over all possible quark and antiquark flavours and \( q \) and \( \bar{q} \) are conjugate in flavour. The respective squared amplitudes, averaged
over the incoming helicities and colours and multiplied by the flux factor $1/(2s)$ are given by

\begin{align}
R_{gg} &= \frac{\alpha_s^3}{12\pi} \frac{G_F}{\sqrt{2}} \frac{1}{2s} s^4 + t^4 + u^4 + M^8 \left( stu \right), \\
R_{gq} &= -\frac{\alpha_s^3}{27\pi} \frac{G_F}{\sqrt{2}} \frac{1}{2s} s^2 + u^2 \left( t \right), \\
R_{qg} &= -\frac{\alpha_s^3}{27\pi} \frac{G_F}{\sqrt{2}} \frac{1}{2s} s^2 + t^2 \left( u \right), \\
R_{q\bar{q}} &= 8\frac{\alpha_s^3}{81\pi} \frac{G_F}{\sqrt{2}} \frac{1}{2s} t^2 + u^2 \left( s \right),
\end{align}

where

\begin{align}
s &= (k_1 + k_{\oplus})^2 = \frac{M^2}{1 - \xi}, \\
t &= (k_1 - k_{\ominus})^2 = -\frac{s}{2}(1 + y), \\
u &= (k_1 - k_{\bar{\ominus}})^2 = -\frac{s}{2}(1 - y).
\end{align}

In terms of the FKS variables we then have

\begin{align}
R_{gg} &= \frac{\alpha_s^3}{12\pi} \frac{G_F}{\sqrt{2}} \frac{1}{4} \left[ 8 + (y^4 + 6y^2 + 1) \xi^4 + 8(1 - \xi)^4 \right] \frac{1}{\xi^2(1 - y^2)}, \\
R_{gq} &= \frac{\alpha_s^3}{27\pi} \frac{G_F}{\sqrt{2}} \frac{1}{4} \left[ 4 + (1 - y)^2 \xi^2 \right] \frac{1}{\xi(1 + y)}, \\
R_{qg} &= \frac{\alpha_s^3}{27\pi} \frac{G_F}{\sqrt{2}} \frac{1}{4} \left[ 4 + (1 + y)^2 \xi^2 \right] \frac{1}{\xi(1 - y)}, \\
R_{q\bar{q}} &= \frac{8\alpha_s^3}{81\pi} \frac{G_F}{\sqrt{2}} \frac{1}{4} \left[ \xi^2(1 + y^2) \right],
\end{align}

where the singular behavior for a soft ($\xi \to 0$) or collinear gluon ($y \to \pm 1$) is clearly manifest. Notice that the contribution $R_{q\bar{q}}$ is not singular and has no underlying Born.

### 2.2.4 Collinear remnants

After the subtraction of the initial-state collinear singularities into the parton distribution functions, finite collinear remnants are left over. The kinematics of these terms is Born-like. More precisely, we can introduce two sets of variables, $\Phi_{1,\oplus} = \{M^2, Y, z\}$, such that momentum conservation reads

\begin{align}
z x_{\oplus} K_{\oplus} + x_{\ominus} K_{\ominus} &= k_1
\end{align}

for the $\oplus$ direction and

\begin{align}
x_{\oplus} K_{\oplus} + z x_{\ominus} K_{\ominus} &= k_1
\end{align}

for the $\ominus$ one. We can then associate an underlying Born configuration $\Phi_{1}$ such that

\begin{align}
\bar{k}_{\oplus} = z x_{\oplus} K_{\oplus}, \quad \bar{k}_{\ominus} = x_{\ominus} K_{\ominus}, \quad \bar{k}_1 = k_1
\end{align}

for the $\oplus$ direction, and

\begin{align}
\bar{k}_{\ominus} = x_{\ominus} K_{\ominus}, \quad \bar{k}_{\bar{\ominus}} = z x_{\ominus} K_{\ominus}, \quad \bar{k}_1 = k_1
\end{align}
for the ⊕ one.

The collinear remnants are given in eq. (2.102) of ref. [9], where we have fixed \( \xi_c = 1 \) and \( \delta_I = 2 \) and chosen the \( \overline{\text{MS}} \) renormalization scheme. For the ⊕ direction and for the two different real-term contributions, they are given by

\[
G_{g\oplus} (\bar{\Phi}_1, \oplus) = \frac{\alpha_S}{2\pi} C_F \left\{ (1 - z) \frac{1 + (1 - z)^2}{z} \left[ \left( \frac{1}{1 - z} \right)_+ \log \left( \frac{M^2}{z\mu_F^2} \right) \right.ight.
\]
\[
+ 2 \left( \log \left( \frac{1 - z}{1 - z} \right)_+ \right] + z \} \mathcal{B}_{gg}, \quad (3.36)
\]

\[
G_{\bar{g}\oplus} (\bar{\Phi}_1, \oplus) = \frac{\alpha_S}{2\pi} 2C_A \left[ z + \frac{(1 - z)^2}{z} + z(1 - z)^2 \right] \left[ \left( \frac{1}{1 - z} \right)_+ \log \left( \frac{M^2}{z\mu_F^2} \right) \right.
\]
\[
+ 2 \left( \log \left( \frac{1 - z}{1 - z} \right)_+ \right] + z \} \mathcal{B}_{gg}. \quad (3.37)
\]

The other two collinear remnants, \( G_{g\ominus} (\bar{\Phi}_1, \ominus) \) and \( G_{\bar{g}\ominus} (\bar{\Phi}_1, \ominus) \), have the same functional form of \( G_{g\oplus} (\bar{\Phi}_1, \oplus) \) and \( G_{\bar{g}\oplus} (\bar{\Phi}_1, \oplus) \) respectively, since \( \mathcal{B}_{gg} \) only depends upon \( k_F^2 \).

3. **POWHEG** implementation

3.1 Generation of the Born variables

The first step in the **POWHEG** implementation is the generation of the Born kinematics. According to ref. [9], we introduce the \( \mathcal{B}(\bar{\Phi}_1) \) function, defined as

\[
\mathcal{B}(\bar{\Phi}_1) = B_{gg}(\bar{\Phi}_1) + V_{gg}(\bar{\Phi}_1) + \int d\Phi_{\text{rad}} \left\{ \mathcal{R}_{gg}(\bar{\Phi}_1, \Phi_{\text{rad}}) \right. \\
+ \sum_q \left[ \mathcal{R}_{qg}(\bar{\Phi}_1, \Phi_{\text{rad}}) + \mathcal{R}_{gq}(\bar{\Phi}_1, \Phi_{\text{rad}}) \right] \}
\]
\[
+ \int_{x_{\ominus}}^1 \frac{dz}{z} \left[ G_{g\ominus}(\bar{\Phi}_{1,\ominus}) + \sum_q G_{q\ominus}(\bar{\Phi}_{1,\ominus}) \right] + \int_{x_{\oplus}}^1 \frac{dz}{z} \left[ G_{g\oplus}(\bar{\Phi}_{1,\oplus}) + \sum_q G_{q\oplus}(\bar{\Phi}_{1,\oplus}) \right], \quad (3.1)
\]
where

\begin{align}
B_{gg}(\Phi_1) &= B_{gg}(\Phi_1) \mathcal{L}_{gg}(\bar{x}_\oplus, \bar{x}_\ominus), \\
V_{gg}(\Phi_1) &= V_{gg}(\Phi_1) \mathcal{L}_{gg}(\bar{x}_\ominus, \bar{x}_\ominus), \\
\hat{R}_{gg}(\Phi_1, \Phi_{rad}) &= \hat{R}_{gg}(\Phi_1, \Phi_{rad}) \mathcal{L}_{gg}(x_\oplus, x_\ominus), \\
\hat{R}_{gg}(\Phi_1, \Phi_{rad}) &= \hat{R}_{gg}(\Phi_1, \Phi_{rad}) \mathcal{L}_{gg}(x_\ominus, x_\ominus), \\
G^{gg}_{\oplus}(\Phi_1, \ominus) &= G^{gg}_{\oplus}(\Phi_1, \ominus) \mathcal{L}_{gg}(\bar{x}_\oplus, \bar{x}_\ominus), \\
G^{gg}_{\ominus}(\Phi_1, \ominus) &= G^{gg}_{\ominus}(\Phi_1, \ominus) \mathcal{L}_{gg}(\bar{x}_\ominus, \bar{x}_\ominus), \\
G^{gg}_{\ominus}(\Phi_1, \ominus) &= G^{gg}_{\ominus}(\Phi_1, \ominus) \mathcal{L}_{gg}(\bar{x}_\ominus, \bar{x}_\ominus), \\
G^{gg}_{\ominus}(\Phi_1, \ominus) &= G^{gg}_{\ominus}(\Phi_1, \ominus) \mathcal{L}_{gg}(\bar{x}_\ominus, \bar{x}_\ominus),
\end{align}

with $x_\oplus, x_\ominus$ given in eq. (2.12) and the luminosity $\mathcal{L}$ is defined in terms of the parton distribution functions $f_{f'}^\ominus(x_\ominus, \mu_F^2)$

\begin{equation}
\mathcal{L}_{f'f}(x_\ominus, x_\ominus) = f_{f}^\ominus(x_\ominus, \mu_F^2) f_{f'}^\ominus(x_\ominus, \mu_F^2).
\end{equation}

Observe that the $R_{gg}$ term does not appear in $\hat{B}$, since it does not have a valid underlying Born. It is just generated separately, as described at the end of this section.

All the integrals appearing in eq. (3.1) are finite. In fact, according the the FKS subtraction scheme, the hatted functions

\begin{equation}
\hat{\mathcal{R}}_{ij} = \frac{1}{\xi} \left\{ \frac{1}{2} \left( \frac{1}{\xi} \right) \left[ \left( \frac{1}{1-y} \right) + \left( \frac{1}{1+y} \right) \right] \right\} \left[ (1-y^2) \xi^2 \mathcal{R}_{ij} \right]
\end{equation}

have only integrable divergences. Some care should still be used when dealing with the plus distributions. In order to illustrate this, we explicitly show how to deal with the $\mathcal{R}_{gg}$ term, that is the most singular one. According to eq. (3.12), it can be written

\begin{equation}
\hat{\mathcal{R}}_{gg} = \frac{\alpha_s^3}{12\pi} \frac{G_F}{\sqrt{2}} \left[ 2 + \frac{y^4 + 6y^2 + 1}{4} \xi^4 + 2(1-\xi^4) \right] \left\{ \frac{1}{2} \left( \frac{1}{\xi} \right) \left[ \left( \frac{1}{1-y} \right) + \left( \frac{1}{1+y} \right) \right] \right\} \frac{1}{\xi}.
\end{equation}

Inserting now the expression (2.19) of $d\Phi_{rad}$ into eq. (3.1), we have

\begin{equation}
\int d\Phi_{rad} \mathcal{L}_{gg}(x_\oplus, x_\ominus) \hat{\mathcal{R}}_{gg} = \frac{M^2}{4\pi^3} \int_0^1 dy \int_0^{\xi_M(y)} d\xi \frac{\xi}{(1-\xi)^2} \int_0^{2\pi} d\phi \mathcal{L}_{gg}(x_\oplus, x_\ominus) \hat{\mathcal{R}}_{gg},
\end{equation}

where $\xi_M(y)$ is given in eq. (2.14). The integration over the azimuthal angle $\phi$ is straightforward, giving an overall multiplicative factor of $2\pi$. Considering then the $(1/(1-y))^+$ term only, we get an integral of the form

\begin{equation}
I = \int_0^1 dy \int_0^{\xi_M(y)} d\xi \left( \frac{1}{\xi} \right) \left( \frac{1}{1-y} \right) f(\xi, y) \mathcal{L}_{gg}(x_\oplus, x_\ominus)
\end{equation}
where

\[ f(\xi, y) = \frac{e^3}{12\pi} \frac{G_F}{\sqrt{2}} \left[ 2 + y^4 + 6y^2 + 1 \xi^4 + 2(1 - \xi)^4 \right] \frac{1}{4} M_1^2 \frac{2\pi}{(4\pi)^3} \right. \]

(3.16)

Recalling the definition of the plus distributions

\[ \int_0^1 d\xi \frac{1}{\xi} f(\xi) = \int_0^1 d\xi \frac{f(\xi) - f(0)}{\xi}, \]

(3.17)

\[ \int_{-1}^1 dy \frac{1}{1-y} f(y) = \int_{-1}^1 dy \frac{f(y) - f(1)}{1-y}, \]

(3.18)

and making the change of variable

\[ \xi = \xi_M(y) \xi, \]

(3.19)

we are left with

\[ I = \int_{-1}^1 dy \left( \frac{1}{1-y} \right) f(0, y) \log \xi_M(y) \mathcal{L}_{gg}(x_{\oplus}, x_{\oplus}) \]

\[ + \int_{-1}^1 dy \left( \frac{1}{1-y} \right) f(0, y) \log \xi_M(y) \mathcal{L}_{gg}(x_{\oplus}, x_{\oplus}) \]

\[ = \int_{-1}^1 dy \left( \frac{1}{1-y} \right) \int_{-1}^1 d\xi \left[ f(\xi, y) \mathcal{L}_{gg}(x_{\oplus}, x_{\oplus}) - f(0, y) \mathcal{L}_{gg}(x_{\oplus}, x_{\oplus}) \right] \]

\[ + \int_{-1}^1 dy \left( \frac{1}{1-y} \right) \left[ f(0, y) \log \xi_M(y) - f(0, 1) \log \xi_M(1) \right] \mathcal{L}_{gg}(x_{\oplus}, x_{\oplus}) \]

\[ = \int_{-1}^1 dy \int_0^1 d\xi \left( \frac{1}{1-y} \right) \left\{ \left[ f(\xi, y) \mathcal{L}_{gg}(x_{\oplus}, x_{\oplus}) - f(0, y) \mathcal{L}_{gg}(x_{\oplus}, x_{\oplus}) \right] \right\} \]

\[ \left. \left. - \left[ f(\xi, 1) \mathcal{L}_{gg}(x_{\oplus}, x_{\oplus}) - f(0, 1) \mathcal{L}_{gg}(x_{\oplus}, x_{\oplus}) \right] \right\} \right\} \]

\[ + \int_{-1}^1 dy \left( \frac{1}{1-y} \right) \left[ f(0, y) \log \xi_M(y) - f(0, 1) \log \xi_M(1) \right] \mathcal{L}_{gg}(x_{\oplus}, x_{\oplus}), \]

(3.20)

where we have used the expression of \( x_{\oplus} \) of eq. (2.12) and \( \xi_M(1) = 1 - x_{\oplus} \) (see eq. (2.14)). In the last line we have made the further change of variable

\[ y = -1 + 2 \tilde{y}, \]

(3.21)

so that all radiation variables are mapped into a cubic unit volume. The integral \( I \) is now manifestly finite and can be computed numerically.

The same manipulations should be applied to the \( z \) integration of the collinear remnants in eq. (3.1). For example, concentrating on the two plus distributions in the \( G_{gg} \) term, we have to deal with integrals of the form

\[ \int_{x_{\oplus}}^1 dz \left( \frac{1}{1-z} \right)^+ f(z) = \log(1 - x_{\oplus}) f(1) + \int_0^1 d\xi \frac{f(z) - f(1)}{1 - \xi}, \]

(3.22)

\[ \int_{x_{\oplus}}^1 dz \left( \frac{\log(1-z)}{1-z} \right)^+ f(z) = \frac{1}{2} \log^2(1 - x_{\oplus}) f(1) + \int_0^1 d\xi \frac{\log(1-z)}{1 - \xi} \left[ f(z) - f(1) \right], \]

(3.23)
where \( f(z) \) is finite in the \( z \to 1 \) limit and we have made the change of variable

\[
z = \overline{x} + \tilde{\xi}(1 - \overline{x}) .
\]  

(3.24)

At the end of this procedure, the most general form one can obtain for \( \tilde{B} \) is

\[
\tilde{B}(\Phi_1) = D(\Phi_1) + \int_0^1 d\tilde{\xi} E(\Phi_1, \tilde{\xi}) + \int_0^1 d\tilde{y} \int_0^1 d\tilde{\xi} F(\Phi_1, \tilde{\xi}, \tilde{y}) ,
\]  

(3.25)

and we can define the function

\[
\tilde{B}(\Phi_1, \tilde{\xi}, \tilde{y}) = D(\Phi_1) + E(\Phi_1, \tilde{\xi}) + F(\Phi_1, \tilde{\xi}, \tilde{y}) ,
\]  

(3.26)

so that

\[
\tilde{B}(\Phi_1) = \int_0^1 d\tilde{y} \int_0^1 d\tilde{\xi} \tilde{B}(\Phi_1, \tilde{\xi}, \tilde{y}) .
\]  

(3.27)

In order to generate the underlying Born kinematics, we first compute the two distinct contributions to the total cross section, defined by

\[
\sigma_{\text{tot}} = \sigma_{\tilde{B}} + \sum_q \sigma_{Rqq} ,
\]  

(3.28)

where

\[
\sigma_{\tilde{B}} = \int d\Phi_1 \tilde{B}(\Phi_1) ,
\]

\[
\sigma_{Rqq} = \int d\Phi_1 d\Phi_{\text{rad}} R_{qq}(\Phi_1, \Phi_{\text{rad}}) ,
\]  

(3.29)

and

\[
R_{qq}(\Phi_1, \Phi_{\text{rad}}) = \mathcal{R}_{qq}(\Phi_1, \Phi_{\text{rad}}) \mathcal{L}_{qq}(x_\oplus, x_{\ominus}) .
\]  

(3.30)

We then decide whether the event is a \( \tilde{B} \) event or a \( R_{qq} \) one, with a probability equal to \( \sigma_{\tilde{B}}/\sigma_{\text{tot}} \) and \( \sigma_{Rqq}/\sigma_{\text{tot}} \) respectively. In case of a \( \tilde{B} \) event, the generation of the Born variables \( \Phi_1 \) is performed by using the integrator-unweighter program MINT \([22]\) that, after a single integration of the function \( \tilde{B}(\Phi_1, \tilde{\xi}, \tilde{y}) \) over the Born and radiation variables, can generate a set of values for the variables \( \{ \Phi_1, \tilde{\xi}, \tilde{y} \} \), distributed according to the weight \( \tilde{B}(\Phi_1, \tilde{\xi}, \tilde{y}) \). We then keep the \( \Phi_1 \) generated values only, and neglect all the others, which corresponds to integrate over them. The event is then further processed, to generate the radiation variables, as illustrated in the following section. In case of a \( R_{qq} \) event, one uses the same method used for the \( \tilde{B} \) case, except that, at the end, one keeps the whole set of Born plus radiation variables, that fully defines the kinematics of a real event. In this last case, one does not need to do anything else, and the event is passed to the Les Houches Interface, to be further showered by the Monte Carlo program.
3.2 Generation of the radiation variables

Radiation kinematics is generated using the \textsc{Powheg} Sudakov form factor

$$\Delta(\Phi_1, p_T) = \exp \left\{ - \int d\Phi_{\text{rad}} \frac{R(\Phi_1, \Phi_{\text{rad}})}{B(\Phi_1)} \theta(k_T - p_T) \right\},$$  \hspace{1cm} (3.31)

where we have defined

$$R(\Phi_1, \Phi_{\text{rad}}) = R_{gg}(\Phi_1, \Phi_{\text{rad}}) + \sum_q \left[ R_{qg}(\Phi_1, \Phi_{\text{rad}}) + R_{gq}(\Phi_1, \Phi_{\text{rad}}) \right],$$  \hspace{1cm} (3.32)

$$B(\Phi_1) = B_{gg}(\Phi_1),$$  \hspace{1cm} (3.33)

and

$$k_T^2 = \frac{s}{4} \xi^2 (1 - y^2) = \frac{M^2}{4(1 - \xi)} \xi^2 (1 - y^2)$$  \hspace{1cm} (3.34)

is the exact squared transverse momentum of the radiated parton. The factorization and renormalization scales in eq. (3.31) should be taken equal to \(k_T^2\), in order to recover the correct leading logarithm (LL) Sudakov behavior\(^2\).

To generate the radiation variables, we use the veto method. This requires to find a simple upper bound for the integrand in eq. (3.31)

$$\frac{M^2}{(4\pi)^3} \frac{\xi}{(1 - \xi)^2} \frac{R(\Phi_1, \Phi_{\text{rad}})}{B(\Phi_1)}. \hspace{1cm} (3.35)$$

A suitable upper bounding function is given by

$$U = N \frac{\alpha_s(k_T^2)}{\xi (1 - y^2)},$$  \hspace{1cm} (3.36)

where \(N\) is determined by spanning randomly the whole phase space and imposing that \(U\) is larger than the integrand function. The generation of the event according to the bound (3.36) is documented in great detail in Appendix D of ref. [23], and we do not repeat it here.

The \textsc{Powheg} differential cross section for the generation of the hardest event is given by

$$d\sigma = \bar{B}(\Phi_1) d\Phi_1 \left\{ \Delta(\Phi_1, p_T^{\text{min}}) + \Delta(\Phi_1, p_T) \frac{R(\Phi_1, \Phi_{\text{rad}})}{B(\Phi_1)} d\Phi_{\text{rad}} \right\}$$

$$+ \sum_q R_{q\bar{q}}(\Phi_1, \Phi_{\text{rad}}) d\Phi_1 d\Phi_{\text{rad}}, \hspace{1cm} (3.37)$$

where the last term in the sum is the non-singular real contribution. In the \(\bar{B}\) and \(R_{q\bar{q}}\) functions, the renormalization and factorization scales, \(\mu_R\) and \(\mu_F\), should be taken of the order of the hard scale of the process, i.e. the Higgs boson mass or its transverse mass.

\(^2\)We will show in sec. 4.4 how it is possible to reach next-to-leading logarithmic accuracy for this particular process.
During the generation of radiation, the two scales should instead be taken equal to the transverse momentum of the produced radiation, in order to recover the correct Sudakov form factor.

We remark that, in the formula for the strong coupling constant used for the generation of radiation, we have properly taken into account the heavy-flavour thresholds. That is to say, when the renormalization scale $\mu_R$ crosses a heavy-flavour mass threshold, we change the number of active flavours accordingly. Furthermore, as discussed in refs. [9, 10], we use a rescaled value $\Lambda_{MC} = 1.569 \Lambda^{(5)}_{\overline{MS}}$ in the expression for $\alpha_S$, in order to achieve next-to-leading logarithmic accuracy in the Sudakov form factor (see sec. 4.4 for more details).

4. Results

In this section we present our results, obtained for the Tevatron and the LHC, and the comparison done with $\text{MC@NLO}$ and $\text{PYTHIA}$. We have used the CTEQ6M [24] set for the parton distribution functions and the corresponding returned value $\Lambda^{(5)}_{\overline{MS}} = 0.226$ GeV. In the generation of the radiation, we have fixed the lower cutoff of the transverse momentum to the value $p_{T}^{\min} = \sqrt{5} \Lambda_{MC}$. The renormalization and factorization scales have been taken equal to the Higgs boson transverse mass $m_T^H = \sqrt{m_H^2 + (p_T^H)^2}$.

No acceptance cuts have been applied in any of the following plots.

4.1 POWHEG - $\text{MC@NLO}$ comparison

We have compared our results with $\text{MC@NLO}$, the only existing program where NLO Higgs boson production via gluon fusion is merged with a shower Monte Carlo program. Since $\text{MC@NLO}$ uses only the $\text{HERWIG}$ [5, 6] angular-ordered shower, we have also interfaced $\text{POWHEG}$ with $\text{HERWIG}$, in order to minimize effects due to differences in the shower and hadronization algorithms.

$\text{MC@NLO}$ generates the Higgs boson virtuality $M^2$ according to the Breit-Wigner form

$$\frac{1}{\pi} \frac{m_H \Gamma_H}{(M^2 - m_H^2)^2 + (m_H \Gamma_H)^2}. \quad (4.1)$$

For the purpose of this comparison we have thus used the same form. We have considered two different sets of values for the Higgs boson mass and width: $m_H = 120$ GeV with $\Gamma_H = 3.605$ MeV and $m_H = 400$ GeV with $\Gamma_H = 28.89$ GeV.

Both in $\text{POWHEG}$ and in $\text{MC@NLO}$ there is the option to retain the full top-mass dependence in the Born cross section, i.e. to use a finite $\tau_Q$ value in eq. (2.20). We have then the choice to generate our Born variables by fixing $m_t = 171$ GeV in the $\bar{B}$ term in eq. (3.1) or by sending $m_t \to \infty$. Since we have computed the real-radiation term only in the $m_t \to \infty$ limit, we have to use the same limit in the calculation of the Born term in the Sudakov form factor (3.31), in order to recover the correct Altarelli-Parisi behavior when the collinear limit is approached.
4.1.1 Tevatron results

In fig. 1 we show a comparison between POWHEG and MC@NLO for the rapidity, invariant mass and transverse-momentum distributions of a Higgs boson with $m_H = 120$ GeV, at the Tevatron $p\bar{p}$ collider. The lowest order $m_t$-dependence is retained. A blowup of the transverse-momentum distribution near the low-$p_T$ region is also shown. There is good
agreement between the two programs, except for the transverse momentum distribution at high $p_T$ (we will comment more on this issue in sec. 4.3).

In fig. 2 we compare the leading jet rapidity and the difference in the rapidity of the leading jet and the Higgs boson. The jet is defined using the SISCONE algorithm [25] as implemented in the FASTJET package [26], setting the jet radius $R = 0.7$ and the overlapping fraction $f = 0.5$. As in previous POWHEG implementations, we notice a dip in the MC@NLO jet rapidity distribution, which is enhanced in the difference. We have already extensively discussed this fact in sec. 4.3 of ref. [14].

In fig. 3, we compare the transverse-momentum distributions of the leading jet, reconstructed with the SISCONE and the $k_T$ algorithms (included in FASTJET). A lower 10 GeV cut on jet transverse momentum is imposed. The high-$p_T$ discrepancy reflects the same behavior found for the Higgs boson transverse-momentum distribution (see sec. 4.3).

4.1.2 LHC results

From fig. 4 to 6 we carry out a similar analysis for the LHC $pp$ collider. The difference in the hardness of the $p_T$ distributions is more evident here than at the Tevatron. The other plots show instead a good agreement between the two codes, apart from the aforementioned dip in the leading-jet rapidity distributions.

We have also made some comparisons with a different value of the Higgs boson mass. We have chosen $m_H = 400$ GeV, where the ratio between the Born cross sections evaluated with $m_t = 171$ GeV and $m_t \to \infty$ is close to its maximum value and roughly equals 3. The results are shown in fig. 7 and 8. We see that, in this case, the dip in the rapidity of the hardest jet in MC@NLO is extremely marked.

In the study of ref. [17], carried out in the framework of heavy-flavour production, the origin of the rapidity dip was tracked back to an even stronger dip in the pure HERWIG distribution, that the MC@NLO correction was not able to properly fill. The same pattern is also observed in the present context, as can be seen in fig. 9.
Figure 4: Comparison between POWHEG and MC@NLO for the rapidity, invariant mass and transverse-momentum distributions of a Higgs boson with $m_H = 120$ GeV, at the LHC $pp$ collider.

Figure 5: Comparison between POWHEG and MC@NLO for the rapidity of the leading jet and the rapidity difference of the Higgs boson and the leading jet, defined according to the SISCONE algorithm, with different jet cuts.

4.2 POWHEG - PYTHIA comparison

We now compare POWHEG and PYTHIA. The Higgs boson production implementation in PYTHIA includes matrix-element corrections, so that the $p_T$ distribution of the Higgs boson is accurate at large $p_T$. In our comparisons, we always normalize the PYTHIA results to the full NLO cross section of POWHEG. We use the new $p_T$-ordered shower defined in the PYEVNW
Figure 6: Comparison between POWHEG and MC@NLO for the transverse-momentum distributions of the leading jet, defined according to the SISCONE and the KT algorithms.

Figure 7: Comparison between POWHEG and MC@NLO for the rapidity, invariant mass and transverse-momentum distributions of a Higgs boson with $m_H = 400$ GeV, at the LHC pp collider.

The only difference with respect to the POWHEG-MC@NLO comparisons is in the generation of the Higgs boson virtuality, distributed now according to

$$\frac{1}{\pi} \frac{M^2 \Gamma_H/m_H}{(M^2 - m_H^2)^2 + (M^2 \Gamma_H/m_H)^2},$$

which is very similar to the form used in PYTHIA, except for the fact that PYTHIA includes
threshold effects in the calculation of the Higgs boson width. In fact, PYTHIA uses a running \( \Gamma_H(M^2) \), that increases when a decay channel opens up. The effects of using a fixed or a running \( \Gamma_H \) are more evident for a heavy Higgs boson, as will be shown in the following.

In figs. 10 through 12 we compare results for the Tevatron \( p\bar{p} \) collider, while in figs. 13 through 15 we present results for the LHC. In all the plots we have set \( m_H = 120 \text{ GeV} \). Results are in an impressive good agreement, both for inclusive quantities and for more exclusive ones. The only visible difference is in the transverse Higgs boson momentum distribution at low \( p_T \) at the LHC. This could be due to the different choice of the renormalization and factorization scale in the generation of radiation, our choice being constrained by the requirement of next-to-leading logarithmic accuracy in the Sudakov form factor.

In fig. 16 we present a comparison with \( m_H = 400 \text{ GeV} \). Mass thresholds effects in \( \Gamma_H \) are evident in the invariant-mass distribution generated by PYTHIA. Below \( 2m_t \) the total width is smaller than the fixed one we are using, and PYTHIA results are accordingly lower than ours. All other plots show instead good agreement with POWHEG.
Figure 10: Comparison between POWHEG and PYTHIA for the rapidity, invariant mass and transverse-momentum distributions of a Higgs boson with $m_H = 120$ GeV, at Tevatron $p\bar{p}$ collider. PYTHIA outputs normalized to the POWHEG cross section.

Figure 11: Comparison between POWHEG and PYTHIA for the rapidity of the leading jet and the rapidity difference of the Higgs boson and the leading jet, defined according to the SISCONE algorithm, with different jet cuts. PYTHIA outputs are normalized to the POWHEG cross section.

The good agreement between POWHEG and PYTHIA was to some extent expected. As already observed in refs. [9, 14], the matrix-element correction method used in PYTHIA [27, 28] bears considerable similarities to POWHEG.
Figure 12: Comparison between POWHEG and PYTHIA for the transverse-momentum distributions of the leading jet, defined according to the SISCONE and the KT algorithms. PYTHIA outputs are normalized to the POWHEG cross section.

Figure 13: Comparison between POWHEG and PYTHIA for the rapidity, invariant mass and transverse-momentum distributions of a Higgs boson with $m_H = 120$ GeV, at the LHC. PYTHIA outputs are normalized to the POWHEG cross section.

4.3 The $p_T$ distribution in POWHEG

In this section we address the discrepancy in the $p_T$ distributions in POWHEG and in MC@NLO. First of all, we show in fig. 17 a comparison between the $p_T$ spectrum of POWHEG, MC@NLO and the NLO calculation. For sake of comparison, we have used in POWHEG and in the NLO
calculation the same scale choice adopted in MC@NLO. We point out, however, that using a scale that depends upon the transverse momentum of radiation in POWHEG can only affect the $\bar{B}$ function. More specifically, one ends up using a transverse momentum dependent scale only in calculation of the real contributions in $\bar{B}$, since the transverse momentum is zero for the Born, virtual and collinear remnant terms. Thus, this scale does not depend upon the transverse momentum of the real radiation, that is generated afterwards using the POWHEG Sudakov form factor. The choice of scale for radiation affects instead a single power of the coupling constant, since the Sudakov exponent is proportional to $\alpha_s$. At low transverse momentum, this scale cannot be changed without spoiling the NLL accuracy of the Sudakov form factor. It can be changed, however, at large transverse momentum to explore further uncertainties. However, we have preferred not to implement this possibility. One should recall, in fact, that this scale only affects a single power of $\alpha_s$, and it thus has a much smaller effect than a scale change in the NLO cross section.

We see from fig. 17 that MC@NLO agrees better than POWHEG with the NLO calculation at large $p_T$. Since the difference between MC@NLO and POWHEG should be of next-to-next-to-
leading order (NNLO), the difference between POWHEG and the NLO result should also be of NNLO. In fact we can easily trace the origin of this difference. From eq. (3.37), we infer that, at large $p_T$, the POWHEG differential cross section can be written as

$$d\sigma = \left[ B(\Phi_1) \frac{R(\Phi_2)}{B(\Phi_1)} + \sum_q R_{q\bar{q}}(\Phi_2) \right] d\Phi_1 d\Phi_{rad}, \quad (4.3)$$

since the Sudakov form factor approaches 1 in this region. Neglecting the subdominant $q\bar{q}$ real contribution, this differs from the pure NLO result because of the presence of the factor

$$\frac{B(\Phi_1)}{B(\Phi_1)} = 1 + O(\alpha_s). \quad (4.4)$$

It is known that radiative corrections in Higgs boson production are large, so that the $O(\alpha_s)$ term is in fact of order 1, and thus we find an enhancement that approaches a factor of two.\(^3\) We have performed a clear cut test of this interpretation of the discrepancy. We have replaced the $B$ function with the Born term $B$ in the POWHEG program. The result of

\(^3\)We recall that normally the numerator and denominator in this factor are evaluated at different scales, since in $B$ one uses a scale of the order of the Higgs boson transverse mass, while in the $B$ term, one uses the transverse momentum. However, at large $p_T$, the two scales become of the same order.
Figure 17: Comparison between POWHEG, MC@NLO and the NLO calculation, for $m_H = 120$ GeV at the LHC. All calculations are performed in the $m_t \to \infty$ approximation. Shower and hadronization are included in the MC results. The POWHEG result is also presented without shower and hadronization, and with a fixed-scale choice.

this calculation is shown in comparison with the NLO curve in fig. 18. Since, as shown in fig. 17, the shower and hadronization are irrelevant for this distribution, we do not include them in the figure. In fig. 18 we have chosen to use $p_T$ independent renormalization and factorization scales, in order to perform a consistent comparison. Notice that, with this choice of scales, the NLO distribution is harder than the one shown in fig. 17. This is easily explained by the fact that the NLO process is proportional to $\alpha_S^2(\mu_R)$, and thus a $p_T$ dependent renormalization scale can alter significantly the $p_T$ distribution.

At this point, we can ask whether the higher order terms included in POWHEG with the mechanism illustrated above do in fact give a reasonable estimate of true NNLO effects. We thus include in fig. 18 the NNLO result, obtained from the $HNNLO$ program of ref. [16]. The result shows a rather good agreement between the NNLO result and POWHEG. Thus, our seemingly large corrections to the Higgs boson $p_T$ distributions are in fact very similar in size to the full NNLO result. Observe that in fig. 18 we have used a fixed scale choice for all the results. We were forced to do this, since the $HNNLO$ program does not allow for other choices. However, because of the good agreement of the two POWHEG results in fig. 17, and because of the smaller scale dependence of the NNLO result, this should not make a severe difference.

Because of a fortuitous circumstance, we did not need to worry about correcting for
Figure 18: Comparison between POWHEG and fixed NLO and NNLO distributions for the transverse-momentum of the Higgs boson. Plots are done for $m_H = 120$ GeV at the LHC.

the large difference between the POWHEG and the NLO result at large radiation transverse momentum, since the known NNLO result seems to support the POWHEG one. We remark, however, that, had this not been the case, it is very easy to modify the POWHEG algorithm so to obtain a $p_T$ spectrum that agrees with the NLO calculation at large $p_T$. This can be done as follows. Instead of using the full real cross section for the computation of the $\bar{B}$ function and of the Sudakov form factor, we can instead use a reduced real contribution

$$R_{\text{red}} = R \times F,$$  \hspace{1cm} (4.5)

where $F$ is a function of the real phase space, with $F < 1$ everywhere, such that $F$ approaches 1 for small transverse momenta, and approaches zero for large transverse momenta. We perform the POWHEG generation using $R_{\text{red}}$ instead of $R$, and treat the remaining $R \times (1 - F)$ contribution to the cross section with the same method that we used for the $R_{qq}$ contribution. This can be done, since $R \times (1 - F)$ is dumped by the $1 - F$ factor in the singular region. It will then follow that, for large transverse momentum, the result would agree with the NLO calculation, since it would be dominated by the $R \times (1 - F)$ contribution. It turned out that, in all previous implementations, it was not necessary to use such procedure. As remarked before, thanks to the known properties of the NNLO result, this was not necessary even in this case. We have however performed such study, just in order to illustrate the flexibility of the POWHEG method. We have chosen for $F$ the
The resulting transverse-momentum distribution at the LHC, for a Higgs boson mass of 400 GeV, is shown in fig. 19 for \( h \to \infty \) (standard POWHEG), \( h = 120 \) GeV and \( h = 400 \) GeV. One can see that it is not difficult to get distributions that undershoot the MC@NLO one in the intermediate range of \( p_T \). We also observe that, with this procedure, no undesired features of other distributions appear. In particular, the distribution in the rapidity of the hardest jet, and in the rapidity difference between the hardest jet and the Higgs boson remain qualitatively the same, as shown in fig. 20.

### 4.4 Next-to-leading logarithmic resummation

As explained in section (4.4) of ref. [9], one can reach next-to-leading logarithmic (NLL) accuracy of soft gluon resummation if the number of coloured partons involved in the hard scattering is less or equal to three. This can be obtained by replacing the strong coupling constant in the Sudakov exponent with [29]

\[
\alpha_s \to A \left( \alpha_s \left( k_T^2 \right) \right), \quad A(\alpha_s) = \alpha_s \left\{ 1 + \frac{\alpha_s}{2\pi} \left[ \left( \frac{67}{18} - \frac{\pi^2}{6} \right) C_A - \frac{5}{9} n_f \right] \right\},
\]  

(4.7)
Figure 20: Comparison of the predictions of the standard POWHEG ($h \rightarrow \infty$), and POWHEG with two different values of the parameter $h$ ($h = 120$ GeV and $h = m_H = 400$ GeV) in the function $F$ of eq. (4.6), for the rapidity of the leading jet and the rapidity difference of the Higgs boson and the leading jet, defined according to the SISCONE algorithm, with different jet cuts, at the LHC.

Figure 21: Comparison between POWHEG and HqT for the transverse-momentum distributions of a Higgs boson, at the LHC. The POWHEG result without shower and hadronization is also shown.

where the $\overline{\text{MS}}$, 1-loop expression of $\alpha_s$ should be used. The previous replacement may also be implemented by a simple redefinition of the strong scale $\Lambda$, which, for five active flavours ($n_f = 5$), becomes $\Lambda_{\text{MC}} \equiv 1.569 \Lambda_{\text{MS}}^{(5)}$. We have exploited this possibility in our code, so that our result should agree with the NLL resummed one. A comparison has
been thus carried out with the HQT [30] program, that performs such a resummation. We have adopted fixed renormalization and factorization scales. Results are shown in fig. 21, together with next-to-next-to-leading logarithmic (NNLL) resummation, always from HQT, just for reference purposes. We see a fair agreement between the POWHEG result and the NLL analytic one, as expected. The different behaviour of the POWHEG result without shower and hadronization at very low $p_T$ may be ascribed to the particular implementation of the minimum transverse momentum that we use, that is, to a large extent, arbitrary.

We observe that, in all cases, we do not expect full agreement between the POWHEG result without shower, and the NLL calculation. In fact, the POWHEG curve without shower represents the Sudakov form factor for the $p_T$ of the hardest emission, while, in the NLL calculation, the total $p_T$ distribution (i.e. the sum of the transverse momenta of all emissions) is considered. Thus, it is only after the inclusion of the full shower effects that the two distributions have a meaningful comparison.

5. Conclusions

In this paper we have reported on a complete implementation of Higgs boson production via gluon fusion at next-to-leading order in QCD, in the POWHEG framework. The calculation was performed within the Frixione-Kunszt-Signier [20, 21] subtraction approach. We have also shown how to deal with non-singular real contributions, that do not present a valid underlying Born matrix element.

The results of our work have been compared extensively with MC@NLO and PYTHIA shower Monte Carlo programs. The PYTHIA results, normalized to the total NLO cross section, are in good agreement with POWHEG, except for differences in the low transverse-momentum distributions of the Higgs boson at the LHC. The MC@NLO results are in fair agreement with POWHEG, except for the $p_T$ distribution of the Higgs boson, and consequently of the hardest jet, in the high-$p_T$ region. In this region the POWHEG distributions are generally harder. We have shown that this is due to NNLO effects in the POWHEG formula for the differential cross section. We checked that these effects actually bring our result closer to the NNLO one [16]. The low-$p_T$ region was instead tested against the analytic resummed results [30]. We find again good agreement up to NLL accuracy.

Furthermore, we have also examined the distributions in the difference of the hardest jet and the Higgs boson rapidity. The dip found in previous implementations [10, 11, 14] is still present. We remark that this seems to be a general feature of MC@NLO, since other calculations do not find effects of this kind [17, 18, 19].

The computer code for the POWHEG implementations presented in this paper is available, together with the manual, at the site
