Abstract The variation of the rotor time constant exerts a dominant effect in the performance degradation of the orientation of the rotor flux method of induction machine and the online estimation of the time constant (\( T_r \)) is necessary in order to use it in the flux orientation and keeping the performance of the vector control. We presented our work vector control of induction machine by estimating and online adaptation of the rotor time constant of our machine only by measurement of voltage, current and speed, in line on the machine, to provide information to the orientation block on the variation of the parameter studied \( T_r \).

Keywords Vector Control, Rotor Time Constant, Induction Machine Estimates and Adaptation

1. Introduction

The asynchronous machine constitutes more and more today a high percentage of the motors used for high-performance drives by advantageously replacing the DC motor. But the difficulty for controlling asynchronous machines is the fact that there is a strong coupling between the flux and torque and any action on one affects the other and more the transitional regime of the machine depends on several variables related to each other in a nonlinear way this fact makes its control more complex than direct current machine because it is very difficult to obtain effective decoupling of the two control parameters which are magnetic flux and mechanical torque. To overcome this limitation of the control of induction machines, several techniques use the method of flux-oriented (vector control), allowing decoupling the speed and the flux of the machine. However, these performances degrade at high speed since the de-fluxing turns so necessary and also when the variation of internal parameters and outside the system studied. The interest raised by the indirect method of flux orientation is motivated by no need to measure the flux, unlike the direct method. We start with the presentation of the model of the asynchronous machine for the vector control. Next, we show improved indirect control by the introduction of the algorithm estimator of the time constant. Finally, the results obtained with the proposed algorithm of the \( \hat{T}_r \) estimator with adaptation, and the simulation.

2. Modeling the Machine

The model of the machine used for the control is given in the \((d, q)\) by the following Equations (1):

\[
\begin{align*}
\frac{d}{dt} i_{sd} &= -\lambda_{sd} + \omega_s i_{sq} + \frac{K}{T_r} \phi_r + p\Omega K\phi_{rq} + \frac{1}{\sigma L_s} V_{sd} \\
\frac{d}{dt} i_{sq} &= -\lambda_{sq} - \omega_s i_{sq} - p\Omega K\phi_{rd} + \frac{K}{T_r} \phi_{rq} + \frac{1}{\sigma L_s} V_{sq} \\
\frac{d}{dt} \phi_{rd} &= \frac{L_m}{T_r} i_{sd} - \frac{1}{T_r} \phi_{rd} + (\omega_s - p\Omega)\phi_{rq} \\
\frac{d}{dt} \phi_{rq} &= \frac{L_m}{T_r} i_{sq} - (\omega_s - p\Omega)\phi_{rd} - \frac{1}{T_r} \phi_{rq} \\
\frac{d\Omega}{dt} &= \frac{3}{2} p L_m (\phi_{rd} i_{sq} - \phi_{rq} i_{sd}) - \frac{C_r}{J} f_s \Omega - f_s \Omega
\end{align*}
\]

With

\[
\begin{align*}
T_r &= \frac{L_r}{R_r}; \quad \sigma = 1 - \frac{L_m^2}{L_r L_s} \\
K &= \frac{L_m}{\sigma L_s L_r}; \quad \lambda = \frac{1}{T_r \sigma T_s \sigma} + \frac{1}{T_s \sigma}; \quad \hat{T}_r = \frac{L_s}{R_s}
\end{align*}
\]

The model of the machine in the \((\alpha, \beta)\) used for the estimation of \( T_r \) is given by the following system of Equations (3):
2.1. Vector Control

From the system of equation, the axis is aligned with the rotor flux vector \( \phi_{rd} = \phi_r, \phi_q = 0 \), the following equation (4) system is obtained:

\[
\begin{align*}
\frac{d}{dt} i_{\alpha} &= - \lambda i_{\alpha} + \frac{K}{T_r} \phi_{ra} + p\Omega K \phi_{r\beta} + \frac{1}{\sigma L_s} V_{s\alpha} \\
\frac{d}{dt} i_{\beta} &= - \lambda i_{\beta} - p\Omega K \phi_{ra} - \frac{K}{T_r} \phi_{r\beta} + \frac{1}{\sigma L_s} V_{s\beta} \\
\frac{d}{dt} \phi_{ra} &= \frac{L_m}{T_r} i_{\alpha} - \frac{1}{T_r} \phi_{ra} - p\Omega \phi_{r\beta} \\
\frac{d}{dt} \phi_{r\beta} &= \frac{L_r}{T_r} i_{\beta} + p\Omega \phi_{ra} - \frac{1}{T_r} \phi_{r\beta} \\
\frac{d\Omega}{dt} &= \frac{3}{2} p \frac{L_m}{J L_r} (\phi_{ra} i_{\beta} - \phi_{r\beta} i_{\alpha}) - \frac{C_r}{J} \frac{f_r\Omega}{J} 
\end{align*}
\]

To maintain the dynamic performance of such drives, estimating the time constant of machine and its adaptation with the programmed value at the rotor flux orientation block is required. An adaptation technique of this size has been proposed.

3. Estimator of the Time Constant of Rotor \( T_r \)

To develop the estimator, we take the model of IM in the stationary frame in the stationary reference. The dynamic model of induction motor supplied current is given in this benchmark by

\[
\begin{align*}
V_{s\alpha} &= R_s i_{s\alpha} + \frac{d\phi_{s\alpha}}{dt} \\
V_{s\beta} &= R_s i_{s\beta} + \frac{d\phi_{s\beta}}{dt}
\end{align*}
\]

From which we can deduce the model of MAS powered, using the rotor flux as state variables. This model is given by:

\[
\frac{d\phi_{ra}}{dt} = \frac{R_r}{L_r} [L_m i_{s\alpha} - \phi_{ra}] - \omega_r \phi_{r\beta} \tag{7}
\]

\[
\frac{d\phi_{r\beta}}{dt} = \frac{R_r}{L_r} [L_m i_{s\beta} - \phi_{r\beta}] - \omega_r \phi_{ra} \tag{8}
\]

The mathematical development of the estimator \( T_r \) takes into account the equations of the stator voltages and the calculation of the term \( V_{s\alpha} i_{s\beta} - V_{s\beta} i_{s\alpha} \).

We have

\[
V_{s\alpha} i_{s\beta} - V_{s\beta} i_{s\alpha} = \frac{d\phi_{s\alpha}}{dt} i_{s\beta} - \frac{d\phi_{s\beta}}{dt} i_{s\alpha} \tag{9}
\]

Replace \( \frac{d\phi_{ra}}{dt} \) and \( \frac{d\phi_{r\beta}}{dt} \) by their values given in (8), (9) the expression for the time constant \( T_r \) can be estimated by

\[
T_r = \frac{S_4}{L_r \left( [S_1] - \sigma L_s [S_1] \right) + [S_3]} \tag{10}
\]

With

\[
S_1 = v_{s\alpha} i_{s\beta} v_{s\beta} i_{s\alpha}
\]

\[
S_2 = \frac{d}{dt} i_{s\alpha} i_{s\beta} - \frac{d}{dt} i_{s\beta} i_{s\alpha}
\]

\[
S_3 = \omega_r (\phi_{r\beta} i_{s\phi} + \phi_{ra} i_{s\alpha})
\]

\[
S_4 = \phi_{r\beta} i_{s\alpha} - \phi_{ra} i_{s\beta}
\]

\( S_5 \): Components de \( \phi_{ra}, \phi_{r\beta} \)

The components \( \phi_{ra} \) and \( \phi_{r\beta} \) are estimated by the equations (7) et (8) after integration.

The global schema of the estimator of the time constant rotor and the rotor flux (\( \phi_{ra} \) and \( \phi_{r\beta} \)) in the stationary frame is shown in Figure (1), use this calculator to determine the time constant of the rotor flux and we can so online adapt this time constant in a drive oriented rotor flux.
3.1. Adaptation of the Rotor Time Constant

From measurable quantities of the machine (voltage, current, speed) we estimate $T_r$ using the equation (10). Once determined, we must ensure to maintain the time constant at the orientation block equal to the estimated value of which corresponds to the constant real time of the machine.

Figure 1. Estimator proposed scheme

Figure 2. Diagram control system block with adaptation of $T_r$
3.2. Simulation Results

Characteristic of MAS:

\[ P = 1.5 kW, U = 380 V, N = 1400 \text{tr/min}, \]
\[ R_s = 4.850 \Omega, R_r = 3.805 \Omega, L_s = 274.10^{-3} \text{H}, \]
\[ L_r = 274.10^{-3} \text{H}, L_m = 258.10^{-3} \text{H}, p = 2, J = 0.03 \text{kg.m}^2, \]
\[ f_r = 0.0014 N.m.s/rd, \quad f = 50 \text{Hz}, I = 6.5A \]

We will simulate the closed loop system without adaptation with a variation of the resistance in the first stage, then with adaptation \( T_r \). We tested the system behavior when the rotor resistance varies. The instants 1s and 2s the system is subjected to an application then removing a torque disturbance \( C_r = 10 Nm \).

Note in Figure (3) the rotor flux increases with rotor resistance, so decoupling between flux and torque lost at times 1s and 2s and the estimated flux does not follow the actual flux of the machine the same for the estimated time constant \( T_r \) does not follow real \( T_r \).

As there is no adaptation of the rotor time constantly, one can observe the effect of variation \( T_r \) on the dynamic response of flux and torque at the machine.

It is clearly visible from Figure (4) that the curves that the adaptation constant function of the rotor time is accomplished despite the variation applied to the rotor resistance of the machine.

Figure. 3. Estimation results of the time constant and the rotor flux without adaptation
4. Conclusions

The results of this work on the training adjusted by conventional methods of indirect rotor flux orientation are obtained with improved performance of the control system studied is realized by the development of a blueprint indirect stronger whatever the variation of parameters with online correction of the variation of the time constant of rotor to maintain the decoupling block in perfect agreement with the actual conditions of engine operation.
