Abstract. Long non-coding RNAs (lncRNAs) are a class of RNAs that do not code protein but are important in diverse biological processes. In previous years, with the application of high-throughput sequencing, a large number of lncRNAs associated with virus infections have been identified and intensively investigated, however, there are few studies examining the association between lncRNAs and HCV replication. Previous studies have demonstrated that signal transducer and activator of transcription 3 (STAT3) is activated by the hepatitis C virus (HCV) and in turn increases the replication of HCV. However, the detailed molecular mechanism is only partially understood. In the present study, using human lncRNA polymerase chain reaction (PCR) arrays, it was identified that lnc-IGF2-AS, lnc-7SK, lnc-SChLAP1 and lnc-SRA1 are upregulated by STAT3. In addition, among these four lncRNAs, only lnc-IGF2-AS and lnc-7SK were involved in HCV replication. Transfection of siRNA lnc-7SK and siRNA lnc-IGF2-AS partially inhibited the replication of HCV in Huh7 cells. Data also indicated that when transfected with siRNA Inc-7SK and siRNA Inc-IGF2-AS, the expression of phosphatidylinositol 4-phosphate (PI4P), which was identified to be associated with HCV replication, was reduced. Thus, the present study identified two new types of lncRNAs, lnc-IGF2-AS and lnc-7SK, which can be upregulated by STAT3 and are involved in HCV replication by regulating PI4P.

Introduction

Hepatitis C virus (HCV) is a hepatotropic RNA virus of the genus Hepacivirus in the Flaviviridae family. Since it was identified in 1989, HCV has become a globally spread virus, leading to a worldwide health problem, which requires significant resources for its prevention and control. HCV can cause acute and chronic hepatitis in humans and chimpanzees, and if untreated it may progress to cirrhosis and hepatocellular carcinoma (HCC) (1). HCV is a positive-sense, single-stranded enveloped RNA virus ~9,600 nucleotides in length (2). Signal transducer and activator of transcription (STATs) factors are a family of transcription factors that have essential roles in cell growth, development, proliferation, immune defense and differentiation. Seven members of the STAT family have been identified and characterized, including STAT1, STAT2, STAT3, STAT4, STAT5a, STAT5b and STAT6 (3). Among the STAT family, STAT3 has been identified as a critical regulator in tumor cells (4). The activation of STAT3 may be one of the mechanisms by which human papilloma virus (HPV) achieves oncogenic transformation. E2, an early protein of HPV16, potentiates tumor necrosis factor (TNF)-α-mediated nuclear factor-κB activation through activation of STAT3 in the presence of TNF-α. In addition, this results in the reversal of E2-induced apoptosis, leading to cell survival (5). Tacke et al found that extracellular HCV core protein activates STAT3 in human monocytes, macrophages and dendritic cells (DCs) through an interleukin (IL)-6 autocrine pathway (6). However, the specific mechanism underlying how STAT3 is involved in the regulation of HCV replication remains to be elucidated.

Non-coding RNAs (ncRNAs) are transcribed RNA molecules with little or none protein coding capacity. Among all types of ncRNAs, long non-coding RNAs (lncRNAs), a type of regulatory ncRNA, are crucial in almost every aspect of cellular processes (7). Zhang et al found that nuclear enriched abundant transcript 1 (NEAT1) is one of several lncRNAs whose expression is altered by human immunodeficiency virus type 1 (HIV-1) infection and the knockdown of NEAT1 enhanced HIV-1 production through increased nucleus-to-cytoplasm export of Rev-dependent instability element-containing HIV-1 mRNAs (8). According to a large number of studies, lncRNAs are also associated with the development and progression of HCV, which causes HCC (9-12). A number of previous studies

Key words: long non-coding RNAs, signal transducer and activator of transcription 3, hepatitis C virus replication, phosphatidylinositol 4-phosphate
have implicated phosphatidylinositol 4-phosphate (PI4P) and several interacting partners in HCV infection (13-16). It has been demonstrated that host phosphatidylinositol 4-kinase and its product PI4P are involved in HCV replication and exert their effect through the effector oxysterol-binding protein (17). However, there are no relevant studies investigating whether lncRNAs can affect HCV replication through regulating PI4P. Therefore, identifying the association between lncRNAs regulated by STAT3 and PI4P expression may provide a novel pathogenic mechanism and therapeutic target for HCV infection.

In order to clarify the detailed molecular mechanism of how STAT3 promotes the replication of HCV, human lncRNA polymerase chain reaction (PCR) arrays were used to identify the lncRNAs regulated by STAT3 in the current study. Finally, the mechanism underlying the regulation of HCV replication by lnc-7SK and lnc-IGF2-AS was investigated.

Materials and methods

Cell culture and virus. Human hepatoma cells (Huh7; American Type Culture Collection, Manassas, VA, USA) are a cell line highly permissive for HCV replication (18). Cells were cultured in Dulbecco's modified Eagle's medium (DMEM) medium (HyClone Laboratories, Inc., Logan, UT, USA) with 10% fetal bovine serum (FBS; HyClone Laboratories, Inc.) and cell culture plates were all placed in a humidified 5% CO₂ incubator at 37°C.

The genotype 2a HCV strain JFH-1 was produced and propagated as described by Wakita et al. (19).

Lentiviral vector construction and transfection. The lentiviral vector system contains GV-166, pHelper1.0 and pHelper2.0. pHelper1.0 and pHelper2.0 contain essential elements for virus packaging. The STAT3 gene was amplified by PCR and then inserted at a unique AgeI site and BamHI site in the vector (GV-166) to construct the GV166-STAT3 plasmid using the following primers: STAT3, forward ATGGGACACTGGTGAGGAT and reverse CGGCAAGTCTAATGGTATTC. E. coli was transformed with GV166-STAT3 and cultured overnight at 37°C. PCR of the connected product was performed and the PCR array amplification was conducted using an IQ5 machine (Bio-Rad Laboratories, Inc., Hercules, CA, USA) and the conditions were set as follows: 15 sec at 95°C, followed by 40 cycles of 15 sec at 95°C, 30 sec at 65°C and 30 sec at 72°C. Subsequently, a melt curve analysis was performed to determine the specificity of the PCR reaction. Relative gene expression was calculated using the ΔΔCt method (20). Primers used for qPCR are summarized in Table I.

Reverse transcription-qPCR. Reverse transcription of RNA was performed according to the manufacturer's instructions of the Reverse Transcription System (Promega Corporation, Madison, WI, USA). The primers were designed using the NCBI primer blast tool (http://www.ncbi.nlm.nih.gov/tools/primer-blast/). The PCR system contained 2 µl of diluted cDNA, 12.5 µl of Fast SYBR Green Master mix (Invitrogen Life Technologies) and 10 µM of each gene specific primer in a total volume of 25 µl. qPCR reactions were performed in triplicate in 96-well plates under the following conditions: 15 sec at 95°C, followed by 40 cycles of 15 sec at 95°C, 30 sec at 65°C and 30 sec at 72°C.

siRNA transfection. Monolayers of Huh7 cells with 70% confluence in 6-well plates were transfected with siRNA lncRNA-SChLAP1, siRNA lncRNA-SRA1, siRNA lncRNA-IGF2-AS and siRNA lncRNA-7SK. Transfection was performed using Lipofectamine™ 2000 (Invitrogen Life Technologies) according to the manufacturer's instructions. In brief, Huh7 cells (in serum free DMEM) were transfected using different quantities of Lipofectamine™ 2000 according to the quantity of siRNA. At 8 h post infection, the cells were harvested to measure the viral gene mRNA level by qPCR or PI4P-kinase level by western blot analysis. Four
pairs of siRNA sequences were designed and synthesized by Shanghai GenePharma Co., Ltd. (Shanghai, China). The negative control sequence was a missense sequence. The sequences of the four siRNAs are provided in Table II.

**Western blot analysis.** Cells were collected by trypsinization. Total protein was extracted using RIPA plus phenylmethylsulfonyl fluoride according to the manufacturer's instructions (Beyotime Institute of Biotechnology, Shanghai, China). The protein samples were diluted in 5X loading buffer, boiled for 10 min, subjected to a 10% polyacrylamide gel (Sangon Biotech Co., Ltd., Shanghai, China) and then underwent electrophoresis. The proteins were transferred onto polyvinylidene fluoride membranes (EMD Millipore, Billerica, MA, USA). Following transfer, the membranes were blocked with 5% (w/v) non-fat dry milk in Tris-buffered saline and Tween 20 (TBST; 10 mM Tris- HCl, pH 8.0, 150 mM NaCl containing 0.1% v/v Tween 20) for at least 1 h and then the membranes were incubated overnight at 4°C with the following monoclonal antibodies from Abcam (Cambridge, MA, USA): Mouse monoclonal STAT3 (ab119352; 1:5,000), mouse monoclonal HCV-E2 (ab20852; 1:100) and rabbit monoclonal PI4K-β (ab109418; 1:1,000). Following being washed three times with TBST, the membranes were incubated with the following secondary antibodies (CST) from Abcam: Goat anti-mouse (ab131368; 1:5,000), goat anti-rabbit (ab7085; 1:1,000) for 30 min and were revealed using an ECL PLUS detection kit (Biomiga, Inc., San Diego, CA, USA). β-actin was obtained from Sigma-Aldrich.

**Table I. Primer sequences used for quantitative polymerase chain reaction.**

| LncRNAs   | Primer sequence                                      |
|-----------|------------------------------------------------------|
| Lnc-7SK   | F: 5'-AAACAAGCTCTCAAGGTC-3'  
R: 5'-CTTCATTTGGAATGTGCT-3' |
| Lnc-SRA1  | F: 5'-TTACAGAGATTAGAACCACATT-3'  
R: 5'-GGCAAGTCAAGTTACAAT-3' |
| Lnc-IGF2-AS | F: 5'-CGCCACTGTTACCCATT-3'  
R: 5'-TTGCCCATCCAGATAAGA-3' |
| LncRNA-SChLAP1 | F: 5'-ACACAAGGTCCACCTCCAG-3'  
R: 5'-GGTGCTATCGCATCCCAG-3' |

**Table II. siRNA sequences of the four lncRNAs.**

| LncRNAs       | siRNA sequences                                      |
|---------------|------------------------------------------------------|
| LncRNA-7SK    | 5'-GCTCTCAAGGTCATTTTGTAGGAGA-3'                      |

siRNA, small interfering RNA; lncRNAs, long non-coding RNAs; IGF2, insulin-like growth factor 2; SRA1, steroid receptor RNA activator 1.

**Results**

**Overexpression of STAT3.** In order to identify the lncRNAs regulated by STAT3, a stable transfection cell line of STAT3 was established. qPCR demonstrated that the quantity of STAT3 mRNA in the cells transfected with GV166-STAT3 was significantly higher than that in the GV166-control transfected cells. The western blot assay of STAT3 demonstrated that the concentration of STAT3 in the GV166-STAT3 transfected cells was higher than that of the control cells (Fig. 1).

**STAT3 upregulates four lncRNAs.** Following identification of the stable transfection of STAT3, lncRNA PCR array method was used to detect the different expression levels of lncRNAs in STAT3 overexpressing and control cells. As shown in Fig. 2A, Lnc-IGF2-AS, Lnc-7SK, Lnc-SChLAP1 and Lnc-SRA1
were upregulated in STAT3 overexpressing cells compared with the control cells. To further certify the preliminary result, qPCR was performed. The histogram in Fig. 2B confirmed that STAT3 is able to increase these four lncRNAs.

**LncRNA-7SK and lncRNA-IGF2-AS siRNA inhibits HCV replication.** As these four lncRNAs can be upregulated by STAT3, the present study aimed to determine whether these four lncRNAs have a direct association with HCV replication. To verify the involvement of these four lncRNAs in HCV replication, the Huh7 cells were transfected with siRNA lncRNA-IGF2-AS, siRNA lncRNA-7SK, siRNA lncRNA-SChLAP1 and siRNA lncRNA-SRA1, and the expression of all these four lncRNAs were analyzed at the mRNA level. The qPCR data shown include at least three independent experiments. As shown in Fig. 3A, the relative expression of the four lncRNAs in Huh7 cells transfected with siRNA lncRNA-IGF2-AS, siRNA lncRNA-7SK, siRNA lncRNA-SChLAP1 and siRNA lncRNA-SRA1, respectively, were significantly lower than cells transfected with the control siRNA (P<0.005).

Subsequently, the siRNA-transfected Huh7 cells were infected with the HCV JFH-1 strain and the cell lysates were analyzed by qPCR and western blot analysis to measure the expression level of the envelope glycoprotein E2. Notably, it was observed that only following transfection of siRNA lncRNA-7SK and siRNA lncRNA-IGF2-AS, the mRNA level of E2 was reduced by 71.5 and 70.9%, respectively, compared with the negative control. While the transfection of siRNA lncRNA-SAR1 and siRNA lncRNA-SChLAP1 had no pronounced effect on the E2 mRNA level (Fig. 3B). Subsequently, the western blot assay also demonstrated that knockdown of lncRNA-7SK and lncRNA-IGF2-AS affects the expression of envelope glycoprotein E2 (Fig. 3C). These results suggest that lncRNA-7SK and lncRNA-IGF2-AS rather than lncRNA-SChLAP1 and lncRNA-SRA1 are associated with the replication of HCV.

**LncRNA-7SK and lncRNA-IGF2-AS siRNA inhibit HCV replication by reducing the expression of PI4P.** In order to investigate the potential mechanism by which siRNA lncRNA-7SK and siRNA lncRNA-IGF2-AS inhibited HCV replication, the expression level of PI4P-kinase, which has been verified to be involved in HCV replication, was measured by western blot analysis. Huh7 cell lysates were obtained following transfection with siRNA lncRNA-IGF2-AS, siRNA lncRNA-7SK as well as infected JFH-1. As expected, the expression of PI4P-kinase was reduced in the cells transfected with siRNA lncRNA-7SK and siRNA lncRNA-IGF2-AS as compared with the negative control. The results were verified through qPCR and western blot analysis (Fig. 4).

**Discussion**

In the present study, two novel findings were reported. Overexpression of STAT3 upregulated Inc-IGF2-AS, Inc-7SK, Inc-SChLAP1 and Inc-SRA1 in Huh7 cells and among these four types of IncRNAs, only Inc-IGF2-AS and Inc-7SK regulated HCV replication through affecting the expression of PI4P. A previous study demonstrated that genetic or pharmacological activation of STAT3 in glioma cells enhanced oncolytic herpes simplex virus replication and cytotoxicity (21). In addition, McCartney *et al* also verified that HCV replication increases STAT3 activation and in turn activation of STAT3 increases HCV replication by modulating microtubule dynamics (22). Activation or overexpression of STAT3 is relevant for...
Figure 3. Knockdown of lnc-7SK and lnc-IGF2-AS by siRNA inhibit HCV replication. (A) Silencing efficiency of lnc-7SK, lnc-SRA1, lnc-IGF2-AS and lnc-SChLAP1 were verified through quantitative polymerase chain reaction. (B) Effects of lnc-7SK, lnc-SRA1, lnc-IGF2-AS and lnc-SChLAP1 knockdown on the mRNA level of the envelope glycoprotein E2. The results are presented as the mean ± standard deviation from three independent experiments performed in triplicate. Relative expression is presented in arbitrary units. (C) Effects of lnc-7SK, lnc-SRA1, lnc-IGF2-AS and lnc-SChLAP1 knockdown on the expression level of E2 were verified through western blot analysis. β-actin was used as an internal control. IGF, insulin-like growth factor; SRA1, steroid receptor RNA activator 1; siRNA, small interfering RNA; HCV, hepatitis C virus; lncRNAs, long non-coding RNAs; NC, negative control.

Figure 4. Knockdown of lnc-7SK and lnc-IGF2-AS leads to the reduction of PI4P expression level. (A) Effect of lnc-7SK and lnc-IGF2-AS knockdown on the mRNA level of PI4P. The results are presented as the mean ± standard deviation from three independent experiments performed in triplicate. Relative expression is presented in arbitrary units. (B) Effects of lnc-7SK and lnc-IGF2-AS knockdown on PI4P expression level were further confirmed through western blot analysis. β-actin was used as an internal control. IGF, insulin-like growth factor; PI4P, phosphatidylinositol 4-phosphate; siRNA, small interfering RNA; NC, negative control. **P<0.005.
various types of human cancer, including Epstein-Barr virus (EBV)-associated cancer. The expression of STAT3 rapidly increases upon EBV infection, which mediates relaxation of the intra-S phase cell-cycle checkpoint, this facilitates viral oncogene-driven cell proliferation (23). HCV core is capable of upregulating the expression of NONOG, which is a member of the homeobox family of DNA binding transcription factors and was identified as a pluripotency promoting gene. In addition, this core-induced NONOG expression enhanced cell growth and cell cycle progression through increased expression of phosphorylated STAT3 protein (24).

LncRNAs are RNAs >200 bp in length. Previous findings have revealed that IncRNAs are involved in several steps of cancer development (25,26). These IncRNAs interact with DNA, RNA and proteins, acting as an essential regulator of cell differentiation and organogenesis. Their misexpression may affect epigenetic information and may result in the progressive and uncontrolled growth of a tumor (11,27). Lnc-DC, which was exclusively expressed in human conventional DCs was involved in DC differentiation and stimulated T-cell activation through interacting with STAT3 (28). The IncRNA-HULC, highly upregulated in liver cancer, is markedly upregulated in HCC, which functions through suppressing the tumor suppressor gene p18 (29). Prensner et al initially identified lnc-SChLAP1 and found that it contributes to the development of lethal prostate cancer at least in part by antagonizing the tumor-suppressive functions of the SWI/SNF chromatin-modifying complex (30). Castelo-Branco et al indicated that the snRNA 7SK, a single non-coding RNA, is a gatekeeper of transcriptional and bidirectional transcription in embryonic stem cells and mediates transcriptional poising through a mechanism independent of chromatin bivalency (31).

In the present study, a stable expression cell line of STAT3 was constructed. Subsequently, a human IncRNA PCR array kit was used. Human LncRNA Profiler was used to compare the LncRNA expression profile differences between Huh7 cells and control cells. It was found that four IncRNAs, including Inc-7SK, Inc-SRAI, Inc-IGF2-AS and Inc-SchLAP1, can be upregulated by STAT3. Among the four IncRNAs, only Inc-7SK and Inc-IGF2-AS are associated with the replication of HCV as the transfection of siRNA lnc-7SK and siRNA lnc-IGF2-AS reduced the expression level of mRNA coding the envelope glycoprotein E2. The expression level of PI4P was then measured in cells following transfection with siRNA lnc-7SK and lnc-IGF2-AS. Compared with cells transfected with siRNA lnc-7SK and siRNA lnc-IGF2-AS, the expression level of mRNA coding the envelope glycoprotein E2‑induced apoptosis. Mol Cell Biochem 394: 77‑90, 2014.
