Freeness and $S$-arithmeticity of rational Möbius groups

A. S. Detinko, D. L. Flannery, and A. Hulpke

Abstract. We initiate a new, computational approach to a classical problem: certifying non-freeness of (2-generator, parabolic) Möbius subgroups of $\text{SL}(2, \mathbb{Q})$. The main tools used are algorithms for Zariski dense groups and algorithms to compute a presentation of $\text{SL}(2, R)$ for a localization $R = \mathbb{Z}[\frac{1}{b}]$ of $\mathbb{Z}$. We prove that a Möbius group $G \leq \text{SL}(2, R)$ is not free by showing that it has finite index in $\text{SL}(2, R)$. Further information about the structure of $G$ is obtained; for example, we compute the minimal subgroup of finite index in $\text{SL}(2, R)$ containing $G$.

1. Introduction

For $x \in \mathbb{C}$, define

$$A(x) = \begin{bmatrix} 1 & x \\ 0 & 1 \end{bmatrix}, \quad B(x) = \begin{bmatrix} 1 & 0 \\ x & 1 \end{bmatrix}.$$  

Let $G(x)$ be the subgroup of $\text{SL}(2, \mathbb{C})$ generated by $A(x)$ and $B(x)$, commonly called a (parabolic) Möbius group. Testing freeness of Möbius groups is a well-studied problem; see, e.g., [1, 3, 12, 15, 17, 18], Sanov [23] proved that $G(2)$ is free, while Brenner [2] proved that $G(x)$ is free (of rank 2) for all $x$ such that $|x| \geq 2$. Hence, if $x$ is algebraic and $|\bar{x}| \geq 2$ for some algebraic conjugate $\bar{x}$ of $x$, then $G(x)$ is free [18, p. 1388]. Also, $G(x)$ is free if $x$ is transcendental [28, pp. 30–31].

It is unknown whether $G(x)$ is free for any rational $x \in (0, 2)$. Overall, testing freeness of matrix groups is difficult. The problem may be undecidable; note that testing freeness of matrix semigroups is undecidable [4]. However, we can effectively decide virtual solvability [10], and so, by the Tits alternative, can decide in practice whether a given finitely generated linear group contains a non-abelian free subgroup (without producing one).

On the other hand, non-freeness of $G(x)$ has been justified for infinitely many rationals in $(0, 2)$, and there is a set of irrational algebraic $x$ that is dense in $(-2, 2)$ and for which $G(x)$ is non-free [1, p. 528].

2000 Mathematics Subject Classification. 20-04, 20G15, 20H25, 68W30.
We take a different approach to certifying non-freeness of Möbius groups in \( \text{SL}(2, \mathbb{Q}) \), that applies recently developed methods to compute with Zariski dense matrix groups \([8,9]\). We now introduce some basic terms. For an integer \( b > 1 \), let \( R \) be the localization \( \mathbb{Z}[\frac{1}{b}] = \{ r/b^i \mid r \in \mathbb{Z}, i \geq 0 \} \) of \( \mathbb{Z} \). Denote \( \text{SL}(2, R) \) by \( \Gamma \). If \( I \subset R \) is a non-zero proper ideal, then there is a unique integer \( t > 1 \) coprime to \( b \) such that \( I = tR \). Let \( \varphi_I : \Gamma \to \text{SL}(2, R/I) \) be the associated congruence homomorphism. The kernel \( \Gamma_I \) of \( \varphi_I \) is a principal congruence subgroup (PCS) of \( \Gamma \). We say that the level \( I \), and \( F \) is the level of the maximal PCS in \( S \). Let \( \text{SL}(2, \mathbb{R}) \) be the localization \( \mathbb{Z} \cdot \mathbb{R} \cdot I \) of \( \mathbb{R} \), respectively. The intersection of all \( S \)-arithmetic subgroups of \( \Gamma \) that contain \( G \) satisfies the congruence subgroup property (CSP): each \( S \)-arithmetic subgroup \( H \) of \( \Gamma \) contains a PCS. The level of \( H \) is defined to be the level of the maximal PCS in \( H \) (the PCS in \( H \) with smallest possible level).

Throughout, unless stated otherwise, \( m = \frac{a}{b} \in \mathbb{Q} \) where \( a \) is a positive integer coprime to \( b \). (Note that \( G(\frac{1}{b}) = \Gamma \).) Since \( G(m) \leq \Gamma \) is Zariski dense in \( \text{SL}(2) \), the intersection of all \( S \)-arithmetic subgroups of \( \Gamma \) that contain \( G(m) \) is \( S \)-arithmetic \([8,9]\). This intersection, called the arithmetic closure of \( G(m) \), is denoted \( \text{cl}(G(m)) \).

For \( G(m) \) is \( S \)-arithmetic then it is not free (see Section 2). Since \( \Gamma \) is finitely presented, one can attempt to prove \( S \)-arithmeticity of \( G(m) \) by coset enumeration. This necessitates determining a presentation of \( \Gamma \). Algorithms for that task are developed in Section 4.1. Then in Section 4.2 we report on experiments carried out using our GAP \([14]\) implementation of the algorithms. There we demonstrate \( S \)-arithmeticity (hence non-freeness) of \( G(m) \) for a range of rational \( m \in (0,2) \). Although non-freeness of some such \( G(m) \) was already known, our experiments illustrate the connection between arithmeticity and non-freeness of \( G(m) \).

Moreover, we provide essential information about the structure and properties of \( G(m) \), covering also the case that \( G(m) \) is a thin matrix group \([24]\), i.e., of infinite index in \( \Gamma \). Specifically, we prove that \( G(m) \) has level \( a^2 \) (Theorem 3.7). Hence, if \( G(m) \) is \( S \)-arithmetic, then we can name the maximal PCS in \( G(m) \), and so readily test membership of elements of \( \Gamma \) in \( G(m) \). The membership testing problem continues to attract attention; see, e.g., \([6,11]\).

We are not aware of any rational \( m \in (0,2) \) such that \( G(m) \) is thin. If there are none, then this would explain the lack of free \( G(m) \) for these \( m \). Conversely, can a thin \( G(m) \) be non-free? Within \( \text{SL}(2, \mathbb{Z}) \), the situation is more settled: \( \text{SL}(2, \mathbb{Z}) \) is a free subgroup of finite index, whereas if \( m \geq 3 \) then \( G(m) \leq \text{SL}(2, \mathbb{Z}) \) is free and thin \([6,\text{Theorem 3}]\) (indeed, for integers \( m > 5 \), the normal closure of \( G(m) \) in \( \text{SL}(2, \mathbb{Z}) \) is thin \([19, \text{p. 31}]\)). Famously, \( \text{SL}(2, \mathbb{Z}) \) does not have the CSP. We remark that \( |\Gamma : G(m)| = \infty \) for any integer \( m \geq 1 \).

This paper is based on preliminary work presented at the ICERM meeting ‘Computational Aspects of Discrete Subgroups of Lie Groups’ (June 14–18, 2021).
2. Non-freeness criteria for Möbius groups

Set \( A = A(m), \ B = B(m), \) and \( G = G(m) \). Each element of \( G \) is a word \( W_n = A^{\alpha_1} B^{\beta_1} \cdots A^{\alpha_n} B^{\beta_n} \) where \( n \geq 1 \) and the \( \alpha_i, \beta_j \) are integers, all of which are non-zero except possibly \( \alpha_1, \beta_n \). If \( G \) is not freely generated by \( A \) and \( B \), then \( G \) is not free \([18], \ p. \ 1394\). Moreover, \( G \) is free and freely generated by \( A, B \) if and only if \( W_n \neq 1 \) for each \( W_n \) with all exponents \( \alpha_i, \beta_j \) non-zero \([22], \ p. \ 158\).

Non-freeness testing of \( G \) by a number of authors \([1,15,18]\) depends on finding words of special form in \( G \). The following is a criterion of such type.

**Lemma 2.1.** If \( N_G(\langle A \rangle) \) is non-cyclic then \( G \) is not free.

**Proof.** The normalizer is upper triangular, hence solvable. \( \square \)

Since \( G \leq G(m/n) \), non-freeness (respectively, \( S \)-arithmeticity) of \( G \) implies that of \( G(m/n) \). So in searching for \( m \in (0, 2) \) such that \( G \) is non-free, we can restrict to \( m \in (1, 2) \) if we wish.

Detecting non-identity elements of finite order is another way to prove non-freeness \([5,12]\). In \([5]\), it is shown that \( G(r) \) for \( r \in \mathbb{Q} \) has a non-identity element of finite order if and only if \( \frac{1}{r} \in \mathbb{Z} \). One direction is simple: \( \text{SL}(2,\mathbb{Z}) \subseteq G(\frac{1}{b}) \), so, e.g., \(-1_2 \in G(\frac{1}{b}) \). An elementary proof of the converse is given below.

**Proposition 2.2.** For \( m = \frac{a}{b} \) where \( a > 1 \), \( G(m) \) is torsion-free.

**Proof.** If \( h \in G \) has prime order, then \( h \) is conjugate to an element of \( \text{SL}(2,\mathbb{Z}) \). The finite order elements of \( \text{SL}(2,\mathbb{Z}) \) are known by a result of Minkowski \([22], \ p. \ 179\); of these, only \(-12 \) is possibly in \( G \leq \Gamma_n \). Hence \( m = \frac{a}{2b} \), \( b \) odd. But this cannot be. For an element of \( G \) looks like

\[
\begin{bmatrix}
1 + m^2 f_1(m) & mf_2(m) \\
mf_3(m) & 1 + m^2 f_4(m)
\end{bmatrix}
\]

where \( f_i(m) \in \mathbb{Z}[m], 1 \leq i \leq 4 \) \([5], \ p. \ 747\]), and after clearing out denominators in the equation \( 2f_1(m) = -b^2 \), we get a contradiction against \( b \) odd. \( \square \)

Our preferred criterion for non-freeness testing follows.

**Proposition 2.3.** Suppose that \( G \) is \( S \)-arithmetic. Then \( G \) is not free.

**Proof.** Since \( \Gamma \) has the CSP, \( \Gamma_c \leq G \) for some \( c \geq 2 \). In turn, \( \Gamma_c \) contains \( \langle A(cR) \rangle = \{ A(cx) \mid x \in R \} \). The latter is isomorphic to the additive group \((cR)^+\) of the ideal \( cR \subseteq R \), and \((cR)^+\) is non-cyclic. \( \square \)

So, our non-freeness test for Möbius subgroups is really a spinoff from attempts to prove \( S \)-arithmeticity in \( \Gamma \).

3. Exploiting Zariski density of Möbius groups

In this section we establish properties of \( G = G(m) \) that derive from Zariski density of \( G \) and the fact that \( \Gamma \) has the CSP. In particular, we find a generating set for \( \text{cl}(G) \).
Denote the set of prime divisors of \( k \in \mathbb{Z} \) by \( \pi(k) \). Let \( \Pi(H) \) be the (finite) set of all primes \( p \) modulo which dense \( H \leq \Gamma \) does not surject onto \( \text{SL}(2, p) \), i.e.,

\[
\Pi(H) = \{ p \in \mathbb{Z} \mid p \text{ prime, } \gcd(p, b) = 1, \varphi_p(H) \neq \text{SL}(2, p) \}.
\]

**Lemma 3.1.** \( \Pi(G) = \pi(a) \).

**Proof.** If \( p \mid a \) then \( G \leq \Gamma_p \); so \( \pi(a) \subseteq \Pi(G) \). If \( p \nmid a \) then \( \varphi_p(G) = \text{SL}(2, p) \), because \( \text{SL}(2, p) = \langle A(k), B(k) \rangle \) for any \( k \in \mathbb{F}_p \setminus \{0\} \).

Let \( l \) be the level of \( G \). Results from \([12]\) imply that \( \Pi(G) \setminus \{2, 3, 5\} = \pi(l) \setminus \{2, 3, 5\} \). We will see that \( l = a^2 \) (Theorem \([3,4]\)); so \( \Pi(G) = \pi(l) \) without exception.

**Remark 3.2.** If \( G \) surjects onto \( \text{SL}(2, p) \) modulo the prime \( p \), then \( G \) surjects onto \( \text{SL}(2, \mathbb{Z}_{p^k}) \) modulo \( p^k \) for all \( k \geq 1 \).

**Lemma 3.3.** Let \( a = p^e c \) where \( p \) is a prime, \( e \geq 1 \), and \( \gcd(p, bc) = 1 \). Then

\[
\Gamma_{p^{2e}} \leq G\Gamma_{p^f}
\]

for any \( f \geq 0 \), but

\[
\Gamma_{p^{2e-1}} \not\leq G\Gamma_{p^f}
\]

if \( f \geq 2e + 1 \).

**Proof.** The lemma is trivially true if \( f \leq 2e \). Suppose that \( f > 2e \). Then \( \Gamma_{p^f} \leq \Gamma_{p^{2e+1}} \leq \Gamma_{p^{2e}} \).

Since \( \gcd(p, bc) = 1 \), there is a positive integer \( i \) such that \( i \cdot c \equiv 1 \mod p^f \), so

\[
A(m)^i \equiv A(p^f) \quad \text{and} \quad B(m)^i \equiv B(p^f) \mod p^f.
\]

Hence \( \varphi_{p^f}(G) = \varphi_{p^f}(G_{p^f}) \). We therefore prove the two assertions with \( G(p^f) \) in place of \( G \).

Setting \( A(p^f) = x \) and \( B(p^f) = y \), we have

\[
[x, y] = \begin{bmatrix}
1 + p^{2e} + p^{4e} & p^{3e} \\
-p^{3e} & 1 - p^{2e}
\end{bmatrix} \equiv \begin{bmatrix}
1 + p^{2e} & 0 \\
0 & 1 - p^{2e}
\end{bmatrix} \mod p^{2e+1}.
\]

It follows that \( U := \varphi_{p^{2e}}(G_{p^f}) \) is abelian, consisting of the \( p^{2e} \) distinct images

\[
\varphi_{p^{2e}} \left( \begin{bmatrix}
1 & sp^e \\
tp^e & 1
\end{bmatrix} \right)
\]

for \( 0 \leq s, t < p^e \). But then \( U \) does not contain

\[
\varphi_{p^{2e}} \left( \begin{bmatrix}
1 + p^{2e-1} & p^{2e-1} \\
-p^{2e-1} & 1 - p^{2e-1}
\end{bmatrix} \right).
\]

Thus \( \varphi_{p^{2e}}(\Gamma_{p^{2e-1}}) \not\leq U \).

It remains to prove the first assertion, and this we do by induction on \( f \). For the base step \( f = 2e + 1 \), note that the images of \( [x, y] \), \( x^{p^e} \), \( y^{p^e} \) under \( \varphi_{p^{2e+1}} \) are

\[
\begin{bmatrix}
1 + p^{2e} & 0 \\
0 & 1 - p^{2e}
\end{bmatrix}, \quad \begin{bmatrix}
1 & p^{2e} \\
0 & 1
\end{bmatrix}, \quad \begin{bmatrix}
1 & 0 \\
p^{2e} & 1
\end{bmatrix}.
\]
These generate the elementary abelian group $\varphi_{p^{2e+1}}(\Gamma_{p^{2e}})$, whose elements are of the form $1 + p^{2e}u$ where $u$ has entries in $\{0, \ldots, p - 1\}$ and trace$(u) \equiv 0$ mod $p$.

Assume now that the statement is true for $f = k \geq 2e + 1$. Then $\varphi_{p^{k}}(\Gamma_{p^{k-1}}) \leq \varphi_{p^{k}}(G(p^e))$. Thus, for each $1 + p^{k-1}u \in \varphi_{p^{k}}(\Gamma_{p^{k-1}})$ where $u$ is a $\{0, \ldots, p - 1\}$-matrix with zero trace modulo $p$, there exist $v \in G(p^e)$ and some $w$ such that $v = 1 + p^{k-1}u + p^kw$. Then $v^p \equiv 1 + p^{k}u \mod p^{k+1}$, which implies that $\varphi_{p^{k+1}}(\Gamma_{p^{k}}) \leq \varphi_{p^{k+1}}(G(p^e))$. Hence $\Gamma_{p^{2e}} \leq \langle G(p^e), \Gamma_{p^{k+1}} \rangle$ by the inductive hypothesis. 

**Remark 3.4.** Lemma 3.3 is valid for $b = 1$.

**Lemma 3.5.** In the notation of Lemma 3.3, $\varphi_{p^{2e}}(G) \cong C_{p^e} \times C_{p^e}$. Hence

$$|\text{SL}(2, \mathbb{Z}_{p^{2e}}) : \varphi_{p^{2e}}(G)| = p^{4e} - p^{4e-2} = p^e |\text{SL}(2, \mathbb{Z}_{p^e})|. $$

**Proof.** We observed that $\varphi_{p^{2e}}(G) = \varphi_{p^{2e}}(G(p^e)) \cong C_{p^e} \times C_{p^e}$ in the proof of Lemma 3.3. Also, $|\text{SL}(n, \mathbb{Z}_{p^e})| = p^{(n^2 - 1)(k - 1)} |\text{SL}(n, p)|$. 

We gather together various observations about the structure of $\text{SL}(2, \mathbb{Z}_{p^e})$, $p$ prime, that are needed in the subsequent proof.

**Lemma 3.6.**

(i) Each proper normal subgroup of $\text{SL}(2, \mathbb{Z}_{p^e})$ has index divisible by $p$.

(ii) Let $l > 1$ be an integer with prime factorization $l = p_1^{i_1} \cdots p_k^{i_k}$. Let $K$ be a subgroup of $\text{SL}(2, \mathbb{Z}_l)$ such that $\varphi_{p_i^{i_i}}(K) = \text{SL}(2, \mathbb{Z}_{p^e})$ for all $i$, $1 \leq i \leq k$. Then $K = \text{SL}(2, \mathbb{Z}_l)$.

**Proof.** (i) A counterexample would arise from a proper normal subgroup of the quotient $\text{PSL}(2, p)$. Hence the statement is clear for $p \geq 5$, and it follows for $p \in \{2, 3\}$ by inspection.

(ii) We proceed by induction on $k$, the base step being trivial. Write $l = rp^e$ where $p$ is the largest prime divisor of $l$ and $\gcd(p, r) = 1$. Then $\text{SL}(2, \mathbb{Z}_l) \cong \text{SL}(2, \mathbb{Z}_p) \times \text{SL}(2, \mathbb{Z}_r)$; so $K$ is a subdirect product of $\varphi_{p_i^{i_i}}(K) = \text{SL}(2, \mathbb{Z}_{p^e})$ and $\varphi_{p_i^{i_i}}(K)$. The inductive hypothesis gives $\varphi_{p_i^{i_i}}(K) = \text{SL}(2, \mathbb{Z}_r)$. Then (i) forces $G$ to be the full direct product $\text{SL}(2, \mathbb{Z}_{p^e}) \times \text{SL}(2, \mathbb{Z}_r)$. This completes the proof by induction.

The next result is the main one of this section, and it facilitates our experiments in the final section.

**Theorem 3.7.**

(i) $\text{cl}(G) = \Gamma_p a^2$ has level $a^2$.

(ii) $|\Gamma : \text{cl}(G)| = a \cdot |\text{SL}(2, \mathbb{Z}_a)|$.

**Proof.** (i) Let $l$ be the level of $G$. If $p^e > 1$ is the largest power of the prime $p$ dividing $a$, then $\Gamma_p a^2$ has level $p^{2e}$ by Lemma 3.3. Since $H := \text{cl}(G) = \Gamma_l \leq \Gamma_p a^2$, and therefore $\Gamma_l \leq \Gamma_p a^2$, we see that $l$ is divisible by $p^{2e}$. Thus $a^2$ divides $l$.

Next we prove $\pi(l) \subseteq \pi(a)$, i.e., $\pi(l) = \pi(a)$. To this end, suppose that $l = rk$ where $r > 1$, $\pi(k) = \pi(a)$, and $\gcd(r, a) = 1$. By Lemma 3.1 Remark 3.2 and
Lemma 3.6 $\varphi_r(G) = SL(2, \mathbb{Z}_r)$. Since $SL(2, \mathbb{Z}_q) \cong SL(2, \mathbb{Z}_r) \times SL(2, \mathbb{Z}_k)$, it follows that $\varphi_l(H) = \varphi_l(G)$ is a subdirect product of $SL(2, \mathbb{Z}_r)$ and $\varphi_k(H)$. Each proper quotient of $SL(2, \mathbb{Z}_r)$ has order divisible by a prime in $\pi(r)$, whereas $\varphi_k(H)$ has order divisible by only the primes in $\pi(a)$. Thus $\varphi_l(H) \cong SL(2, \mathbb{Z}_r) \times \varphi_k(H)$, and as a consequence $\Gamma_k \leq H$. But $\Gamma_l$ is the PCS of least level in $H$.

We have now proved that $\pi(l) = \pi(a)$. Therefore $\varphi_l(H)$ is a direct product of $p$-groups $\varphi_{p^f}(H)$ for $p$ ranging over $\pi(a)$. Suppose that $l > a^2$; say $p^f$ divides $l$ where $f > 2e$ and $p^e$ is the largest power of $p$ dividing $a$. We infer from $\Gamma_{p^{2e}} \leq G \Gamma_{p^f}$ that $\varphi_l(\Gamma_{l/p^f}) \leq \varphi_l(H)$, so $\Gamma_{l/p^f} \leq H$: contradiction. Hence $l = a^2$.

(ii) This follows from Lemma 3.5.

Corollary 3.8. $cl(G)/\Gamma_{a^2} \cong C_a \times C_a$.

The proof of Theorem 3.7 is independent of the denominator $b$, so we have proved additionally that $G(a) \leq SL(2, \mathbb{Z})$ has level $a^2$. Cf. [7] Proposition 1.12; for $n \geq 3$, the ‘elementary group’ in $SL(n, \mathbb{Z})$ generated by all matrices $1_n + me_{ij}$ with $i \neq j$ ($e_{ij}$ has 1 in position $(i, j)$ and zeros elsewhere) contains the PCS of level $m^2$.

In line with [27] (and cf. [7] Proposition 1.10), one can show that $\Gamma_{a^2}$ is generated by $A(am), B(am), B(am)^x$, where $x = \begin{bmatrix} -1 & 1 \\ 0 & 1 \end{bmatrix}$.

Also, at least when $b$ is prime, $\Gamma_{a^2}$ is the normal closure $\langle A(am) \rangle^\Gamma = \langle B(am) \rangle^\Gamma$ of $G(am)$ in $\Gamma$ (this implies the CSP; see [20]). Thus, we get an explicit generating set of $cl(G)$.

Theorem 3.7 and Corollary 3.8 afford further insights. Lifting up to $G$ from a presentation of $\varphi_{a^2}(G) \cong C_a \times C_a$ by the ‘normal generators’ technique (see, e.g., [10] §3.2) yields that $G \cap \Gamma_{a^2}$ is the $G$-normal closure of $\langle A(am), B(am), [A(m), B(m)] \rangle$.

In summary, using the notation $\leq_{f, \infty}$ to denote a subgroup of finite or infinite index, respectively:

1. if $G$ is thin then $G(am) \leq_{f, \infty} cl(G) \leq_{f, \infty} \Gamma_a$;
2. if $G$ is $S$-arithmetic then $G(am) \leq_{f, \infty} \Gamma_{a^2} \leq_{f, \infty} G \leq_{f, \infty} \Gamma_a$;
3. if $G$ is $S$-arithmetic if and only if $\langle A(am) \rangle^\Gamma \leq G$.

When $G$ is $S$-arithmetic, an extra benefit of Theorem 3.7 is that it enables us to test membership of $g \in \Gamma$ in $G$. The idea is obvious: $g \in G$ if and only if $\varphi_{a^2}(g) \in \varphi_{a^2}(G)$. More generally, we could get a negative answer to the question of whether $g$ is in $G$ by testing membership of $g$ in $cl(G)$.

4. Experimentation

4.1. Computing a presentation of $SL(2, R)$. A key requirement for the experiments, which feature Todd–Coxeter coset enumeration, is a presentation of $\Gamma$. Our algorithm to compute one is based on the next theorem, due to Ihara [26] Corollary 2, p. 80].
Theorem 4.1. For any prime $p$, 
\[ \text{SL}(2, \mathbb{Z}[1/p]) \cong \text{SL}(2, \mathbb{Z}) \rtimes \Gamma_0(p) \text{ SL}(2, \mathbb{Z}), \]
the free product with amalgamation $\Gamma_0(p)$, where $\Gamma_0(p)$ comprises all matrices in $\text{SL}(2, \mathbb{Z})$ that are upper triangular modulo $p$.

Theorem 4.1 can be expanded iteratively to $\text{SL}(2, \mathbb{Z}[1/b])$ for composite $b$ [20, p. 80]. If $k$ is an integer not divisible by $p$, then $\text{SL}(2, \mathbb{Z}[1/pk])$ is the amalgamated free product of two copies of $\text{SL}(2, \mathbb{Z}[1/k])$, with the amalgamated subgroup as before comprising all mod-$p$ upper triangular matrices.

We apply Theorem 4.1 in standard fashion (see [26, pp. 80–81]), taking the presentations
\[ \langle s, t \mid s^4 = 1, (st)^3 = s^2 \rangle \quad \text{and} \quad \langle x_p, y_p \mid x_p^4 = 1, (x_py_p)^3 = x_p^2 \rangle \]
of $\text{SL}(2, \mathbb{Z})$, where
\[ s = \begin{bmatrix} 0 & 1 \\ -1 & 1 \end{bmatrix}, \quad t = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}, \quad x_p = \begin{bmatrix} 0 & \frac{1}{p} \\ -p & 0 \end{bmatrix}, \quad y_p = \begin{bmatrix} 1 & -\frac{1}{p} \\ 0 & 1 \end{bmatrix}. \]
We construct a generating set for $\Gamma_0(p)$ whose elements are Schreier generators for the stabilizer of the subspace $\langle (1,0)^T \rangle \subseteq \mathbb{F}_p^2$ under the natural action of $\text{SL}(2, \mathbb{Z})$ modulo $p$. It is easily seen that $[\text{SL}(2, \mathbb{Z}) : \Gamma_0(p)] = p + 1$. Suppose that $\Gamma_0(p)$ is given by a generating set of matrices $w_i = w_i(x,y)$ that are words in $x = x_p$ and $y = y_p$. Utilizing the GAP package ModularGroup [16], we express each $w_i$ as a word $w'_i(s,t)$ in $s$ and $t$. Then $\text{SL}(2, \mathbb{Z}[1/p])$ has presentation
\[ \langle s, t, x, y \mid s^4 = 1, (st)^3 = s^2, x^4 = 1, (xy)^3 = x^2, w_1(x, y) = w'_1(s, t), \ldots, w_k(x, y) = w'_k(s, t) \rangle \]
for some $k \leq p + 2$; of course, this may simplify. However, eliminating redundancy is usually not worthwhile, because it comes at the cost of longer words.

Below are a few examples that illustrate the method.

- Let $p = 5$. Then $\Gamma_0(p)$ is generated by
\[ x^{-2}, xyx^{-1}, y^5, y^2xy^{-2}, yx^{-1}y. \]
Actually, the fifth listed generator is redundant. Now
\[ x^{-2} = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}, \quad xyx^{-1} = \begin{bmatrix} 1 & 0 \\ 5 & 1 \end{bmatrix}, \quad y^5 = \begin{bmatrix} 1 & -1 \\ 0 & 1 \end{bmatrix}, \quad y^2xy^{-2} = \begin{bmatrix} 2 & 1 \\ -5 & -2 \end{bmatrix}. \]
The corresponding words $w'$ are $s^{-2}, t^5, (st)^{-1}, t^{-2}st^2$. Hence
\[ \langle s, t, x, y \mid x^4, xyx^{-2}, s^4, ststst^{-2}, x^{-2}xy^{-2}, x^{-2}s^2, xyx^{-1}t^{-5}, y^5tst, y^2xy^{-2}t^{-2}s^{-1}t^2 \rangle \]
is a presentation of $\text{SL}(2, \mathbb{Z}[1/5])$.
- We similarly calculate that $\text{SL}(2, \mathbb{Z}[1/7])$ has presentation
\[ \langle s, t, x, y \mid s^4, ststst^{-2}, x^4, xyxxyx^{-2}, x^{-2}s^2, xyx^{-1}t^{-7}, y^3x^{-1}t^{-2}st^2, y^{-3}x^{-1}y^2t^3st^{-2} \rangle. \]
The generating set in this example is redundant.
• The results for \( p = 5 \) and \( p = 7 \) combine to give

\[
\text{SL}(2, \mathbb{Z}[\frac{1}{10}]) = \langle s, t, x, y, c, d \mid s^4, stststs^{-2}, x^4, xyxyx^{-2}, x^{-2}s^2, xyx^{-1}t^{-5}, \\
y^5sts, y^2xy^{-2}t^{-2}s^{-1}t^2, c^4, cdcdec^{-2}, c^{-2}c^2, \\
cdc^{-1}t^{-7}, d^{-3}c^{-1}d^2t^4st^{-2}, d^3c^{-1}d^{-2}t^{-3}st^2 \rangle
\]

where \( x = x_5, y = y_5, c = x_7, \) and \( d = y_7. \)

We implemented the above approach as a GAP procedure. This accepts an integer \( b > 1, \) and returns a presentation of \( \Gamma = G(1/b) \) on \( 2 + 2|\pi(b)| \) generators. In our experience, this procedure completed rapidly for prime \( b \approx 2000. \) For composite \( b, \) the cost is basically just that of the prime factors, since the amalgamation is straightforward. For larger \( a, \) we find short word expressions by systematically enumerating all words by increasing length.

### 4.2. \( S \)-arithmeticity of \( G(m). \)

In this section we justify \( S \)-arithmeticity (and thereby non-freeness) of \( G(m) \) for a range of rational \( m \) between 0 and 2.

First, we express the generators \( A = A(m) \) and \( B = B(m) \) of \( G = G(m) \) as words in the generators of \( \Gamma. \) When \( m = a/p \) for a prime \( p, \) this is easy: \( A(a/p) = A(1/p)^a = y^{-a} \) and \( B(a/p) = sy^a s^{-1}. \) For larger \( a, \) we try to find short word expressions by random search. Then we take the subgroup of \( \Gamma \) defined by the words for \( A \) and \( B \) and carry out Todd–Coxeter coset enumeration (within the GAP package ACE [13]). If the enumeration terminates, then rewriting using the modified Todd–Coxeter algorithm of [21] finds relators in \( A \) and \( B. \) Unless \( a \) is small, these relators tend to be long; e.g., the shortest relator discovered for \( m = 4/11 \) is \( A^{121}BA^{-11}B^2A^{-121}B^{-1}A^{11}B^{-2}. \) Relator length typically increases with the index of \( G \) in \( \Gamma \) (governed by \( a; \) Theorem 3.7 (ii)). This suggests that searching for short relators with particular patterns (cf. [11]) has limited chance of proving non-freeness. Also recall that if \( G \) is \( S \)-arithmetic, then it contains upper unitriangular elements \( u \) and \( v \) such that \( \langle u, v \rangle \) is non-cyclic. Once we express \( uvu^{-1}v^{-1} \) as a word in \( A \) and \( B, \) we have a non-trivial relator in \( G. \)

Stages in the coset enumeration may entail significantly (and unboundedly) more cosets than \(|\Gamma : G|, \) so that coset enumeration for \( G \) in \( \Gamma \) may fail to terminate within reasonable time or available memory, even for small indices. We emphasize that failure to terminate is not a proof that \( G \) is thin.

If finite, the index \( a|\text{SL}(2, \mathbb{Z}_a)| \) of \( G(a/b) \) in \( \Gamma \) is greater than \( 10^6, 10^7, 10^8, \) for \( a = 33, a = 59, a = 101, \) respectively. With four generators, and ignoring overhead, each row in the coset table requires at least \( 4 \cdot 2 \cdot 8 = 64 \) bytes of memory. This means that 1GB of memory can store no more than \( 10^7 \) cosets. By this reckoning, we expect that coset enumeration becomes difficult when \( a \) is between 40 and 50. If the index is finite, then we expect that enumeration succeeds if \( a \leq 25. \)

Returning to an earlier point: \( S \)-arithmeticity of \( G(a/b) \) implies \( S \)-arithmeticity of \( G(a/kb) \) for every integer \( k > 0, \) so we could restrict experimentation to groups \( G(a/p) \) where \( p \) is prime. However, the practicality of an attempt to prove \( S \)-arithmeticity of \( G(a/b) \) is affected by the size of \( a. \) Thus, we investigated \( G(m) \)
with $m = a/b < 2$ where $b = p^k$, $p \leq 23$ prime. For each fixed denominator $b$, we found an integer $a_{\text{max}}$ such that $G(a/b)$ is $S$-arithmetic whenever $a \leq a_{\text{max}}$. Table 1 displays output of the experiments.

| $a_{\text{max}}$ | 3 | 7 | 13 | 23 | 37 | 45 | 57 | 5 | 14 | 31 | 41 | 9 | 28 | 39 | 11 | 25 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| $b$ | 2 | 4 | 8 | 16 | 32 | 64 | 128 | 3 | 9 | 27 | 81 | 5 | 25 | 125 | 7 | 49 |

Table 1. Values of $a_{\text{max}}$ and $b$ such that $G(m)$ is $S$-arithmetic for all $m = \frac{a}{b}$, where $a \leq a_{\text{max}}$

We also managed to prove that $G(m)$ is $S$-arithmetic for the following $m = a/b$ where $a$ exceeds $a_{\text{max}}$ for the given $b$: 63/64, 65/64, 44/125, 51/125, 57/125, 29/49.

Unsuccessful enumerations were re-attempted for comparatively small $a$. Here we tried strategies such as increased memory, simplifying the presentation, or use of intermediate subgroups. None of these helped, leading us to suspect that the maximum numerator values up to 30 or so are likely to be correct.

Our experiments show that many $G(m)$ previously known to be non-free are $S$-arithmetic (see [1, 12, 18]). As a single complementary example, we proved that $G(11/19)$ is not free, whereas freeness of $G(11/19)$ was unresolved in [1].

Our GAP code is posted at [https://github.com/hulpke/arithmetic](https://github.com/hulpke/arithmetic).

Acknowledgment. We thank Prof. Vladimir Shpilrain for helpful conversations. We also thank Mathematisches Forschungsinstitut Oberwolfach and Centre International de Rencontres Mathématiques, Luminy, for hosting our visits under their Research Fellowship and Research in Pairs programmes.
