Examining Australian’s beliefs, misconceptions and sources of information for COVID-19: a national online survey

Rae Thomas,1 Hannah Greenwood,1 Zoe A Michaleff,1 Eman Abukmail,1 Tammy C Hoffmann,1 Kirsten McCaffery,2 Leah Hardiman,3 Paul Glasziou1

ABSTRACT

Objective Public cooperation to practise preventive health behaviours is essential to manage the transmission of infectious diseases such as COVID-19. We aimed to investigate beliefs about COVID-19 diagnosis, transmission and prevention that have the potential to impact the uptake of recommended public health strategies.

Design An online cross-sectional survey.

Participants A national sample of 1500 Australian adults with representative quotas for age and gender provided by an online panel provider.

Main outcome measure Proportion of participants with correct/incorrect knowledge of COVID-19 preventive behaviours and reasons for misconceptions.

Results Of the 1802 potential participants contacted, 289 did not qualify, 13 declined and 1500 participated in the survey (response rate 83%). Most participants correctly identified ‘washing your hands regularly with soap and water’ (92%) and ‘staying at least 1.5 m away from others’ (90%) could help prevent COVID-19. Over 40% (incorrectly) considered wearing gloves outside of the home would prevent them from contracting COVID-19. Views about face masks were divided. Only 66% of participants correctly identified that ‘regular use of antibiotics’ would not prevent COVID-19.

Most participants (90%) identified ‘fever, fatigue and cough’ as indicators of COVID-19. However, 42% of participants thought that being unable to ‘hold your breath for 10 s without coughing’ was an indicator of having the virus. The most frequently reported sources of COVID-19 information were commercial television channels (56%), the Australian Broadcasting Corporation (43%) and the Australian Government COVID-19 information app (31%).

Conclusions Public messaging about hand hygiene and physical distancing to prevent transmission appears to have been effective. However, there are clear, identified barriers for many individuals that have the potential to impede uptake or maintenance of these behaviours in the long term. We need to develop public health messages that harness these barriers to improve future cooperation. Ensuring adherence to these interventions is critical.

INTRODUCTION

So far, Australia has done well in its response to COVID-19, but not because of vaccines or drug treatments. The success is due to the use of non-drug interventions, such as physical distancing, hand hygiene and quarantining.1 Maintaining the suppression of major outbreaks is critical but it is predicated on garnering public cooperation to continuously conduct appropriate public health behaviours. In the absence of a vaccine, social cohesion and cooperation to practise COVID-safe behaviours is critical.2 Misinformation about prevention, transmission and treatment of COVID-19 has the potential to derail these efforts.3

Misinformation often fuels misconceptions. Misconceptions about COVID-19, particularly as the disease emerged, have been circulating in the media and online, prompting the WHO to construct a ‘Mythbusters’ webpage.3 Understanding the reasoning behind misconceptions and exploring typical sources
of information can facilitate behaviour change interventions designed to support risk reduction efforts.\(^4\)\(^-\)\(^6\)

Several surveys have explored people’s perceptions, knowledge and attitudes of COVID-19. International and Australian-focused online surveys suggest 71%–93% of participants\(^7\)\(^-\)\(^8\) could identify preventive behaviours (e.g., hand hygiene, physical distancing), but the proportion of individuals who self-report practising these behaviours were fewer, ranging from a low of 45% in a survey of UK participants\(^9\) to 85% in an Australian sample.\(^10\) The difference between the high proportion of people knowing appropriate prevention behaviours and the lower proportion of those reporting to practise the behaviour suggests that knowledge alone is insufficient to change behaviour. This constitutes a knowledge–practice gap. Varying demographic differences have been reported to predict practising preventive behaviours including low socioeconomic status,\(^9\) low health literacy,\(^7\) anxiety\(^7\)\(^-\)\(^10\) and those with high compared with low engagement and perceptions of risk.\(^7\)\(^-\)\(^10\)

The knowledge–practice gap identified in previous surveys requires exploration. To achieve high compliance with infectious disease prevention measures relevant to the current COVID-19 pandemic and future infectious outbreaks, we need to understand the reasoning behind why some people do not practise effective prevention behaviours.\(^4\) Therefore, this survey aimed to (1) identify misconceptions about COVID-19 that have the potential to impact the uptake of the appropriate prevention behaviours (particularly the public health messages from the Australian Government), (2) examine reasons why individuals hold misconceptions for key prevention strategies and (3) identify the most commonly used sources for acquiring COVID-19-related information.

For example, the misconception that ‘keeping your mouth and throat moist’ would prevent COVID-19 was reported from multiple social media platforms. This was categorised as a misconception about preventing COVID-19. However, we categorised this misconception as one that, if believed and enacted, would not negatively impact the prevention or transmission of the virus, and was therefore not included in the survey. Conversely, the misconception that ‘taking antibiotics would prevent COVID-19’ was reported from multiple sources. It was considered a misconception that, if believed, would impact prevention or transmission of COVID-19. For example, if someone takes antibiotics as they believe it protects them from COVID-19, this could potentially increase COVID-19 transmission in the community if they have the virus but believe they are protected (or cured). Hence, this misconception was included in the survey.

The study team included psychologists, medical practitioners and clinical epidemiologists. The survey was piloted with colleagues (including people who have English as a second language) and members of the community if they have the virus but believe they are protected (or cured). Hence, this misconception was included in the survey.
public to ensure face and content validity, and ease of completion.

**Measures**
The survey consisted of five sections (COVID-19 symptoms, prevention strategies, beliefs for ‘incorrect’ prevention strategies, transmission behaviours and information sources for COVID-19). The survey including items, logic, and response scales are reported in online supplemental table 1. The expected time to complete the survey was less than 10 min.

**Statistical analysis**
The primary outcome was the frequency of prevention strategy misconceptions and participant reasoning for each. Descriptive statistics (counts and percentages) were calculated for participant demographic variables and correct/incorrect survey responses. ‘Correct’ and ‘incorrect’ answers for survey questions were determined by the study team via group consensus a priori. With a sample size of 1500, the margin of error around a 50% proportion is ±2.5%. This sample size is similar to most national opinion polls which generally use samples in the range of 1000–2000.

For the open response options, we conducted content analyses of the ‘incorrect’ responses. Two authors (RT and LH) independently coded the first 50 responses and developed an initial coding framework. Uninformative responses (eg, ‘I don’t know’, ‘unsure’) were not coded. Codes were compared and the framework was iteratively developed until consensus was reached. The same two authors tested the refined coding framework on the next 20 responses. Following consensus, one author (RT) completed the qualitative analyses for the remaining responses. Due to the unexpectedly large volume of ‘incorrect’ responses for three items (wearing masks, wearing gloves and staying away from healthcare centres), a random 50% of the responses was coded. All responses were coded for the other four items (use of colloidal silver and essential oils, use of antibiotics, social distancing, washing hands).

**RESULTS**
Of the 1802 potential participants contacted, 289 were screened as ineligible prior to completing the survey and were excluded at that point, 13 declined and 1500 participated in the survey (response rate 83%; see figure 1 for participant flow chart). As per the sampling frame, 50% of survey participants were female, there was a representation across adult age groups and a proportional representation from each Australian state and territory. Participant characteristics are reported in table 1.

**Identifying prevention strategies**
A high proportion of the sample gave correct responses for hand hygiene and 1.5 m physical distancing, but significant proportions were incorrect for the effectiveness of antibiotics, colloidal silver, wearing gloves or masks, and staying away from health centres. Figure 2 shows proportions of participant perceptions of preventive behaviours and table 2 reports the results of the content analyses for the ‘incorrect’ responses.

Although most participants correctly identified ‘washing your hands regularly with soap and water’ (92%), 7% were undecided (‘neither agree or disagree’ or ‘I don’t know’) and a minority (2%) thought that washing their hands would NOT prevent COVID-19. Reasons varied, but the most frequent theme (37.5%) was that participants thought handwashing was unnecessary or ineffective (eg, it was an ‘overreaction’, it would not ‘kill’ the virus, or it is redundant because the participant did not leave the house; see table 2).

Similarly, 90% of participants correctly identified that ‘staying at least 1.5 m away from others’ could prevent COVID-19. Only 34 (2%) participants thought that physical distancing would NOT prevent COVID-19 transmission. Half of those who held that belief reasoned that the strategy was ineffective or unnecessary (eg, ‘stays in the air’ and ‘can float a lot further than that’; see table 2).

Fewer participants correctly identified that ‘regular use of antibiotics’ (66%) would NOT prevent COVID-19, and 22% were unsure. For those who thought that antibiotics could prevent COVID-19 (11%), two dominant themes emerged: an incorrect understanding of antibiotics and treatment options for COVID-19 (eg, they could ‘block viruses’, and ‘prevent’ or ‘kill’ the virus) and erroneously thinking antibiotics would strengthen their immunity.

While 56% of participants correctly identified that taking ‘products like colloidal silver or essential oils’ would NOT prevent a person from contracting COVID-19 and 32% were unsure, and the remainder thought those products would help to prevent COVID-19. Approximately 32% of those who thought colloidal silver and essential oils would prevent COVID-19 appeared to incorrectly understand the transmission process and prevention strategies for COVID-19. For example,
participants reasoned these products would help because they were ‘good in disinfecting’, suggesting transmission only by touch and ‘evidence that colloidal silver is a virus killer’ and the products would ‘kill the germs’.

The two contentious preventative measures of wearing gloves or wearing surgical masks when outside of the home showed conflicting beliefs about the benefits of these behaviours to prevent COVID-19. Over 40% of participants considered wearing gloves outside of the home would help prevent them from contracting COVID-19. Their reasons were nuanced. In the randomly coded sample of 50% (n=299), 33% of participants incorrectly understood the transmission of COVID-19 (eg, ‘won’t come into contact with the virus’, ‘stop transmission’). However, 23% identified plausible self-protection reasons (eg, ‘would not be touching surfaces where it might be on and then touching my face and rubbing my eyes with bare hands’, ‘reduces risk of uptake of pathogen from hands, which in turn reduces risk of transmission from hands to eyes, nose, mouth, etc’).

For ‘wearing of face masks outside of the home’, 28% of participants agreed that this would NOT prevent them (the wearer) from contracting COVID-19, while 42% of participants thought this behaviour was preventative, and the remainder unsure. Within the randomly coded sample, the most frequently provided reason for wearing surgical masks (33%) was an incorrect understanding of COVID-19 transmission (eg, ‘because the virus cannot move via a surgical mask’, ‘you can’t catch it’). Yet, almost a quarter (23%) identified plausible reasons for wearing masks (‘may prevent inhaling droplets from the air which may contain the COVID-19 virus’, ‘it is some form of barrier to my respiratory system’).

Most participants agreed (58%) or were unsure (28%) that staying away from hospitals and health centres would prevent COVID-19 transmissions. Of the randomly coded responses, 52% articulated concerns of infection from test-positive COVID-19 patients and staff, while 13% had reasoned that hospitals and health centres should be avoided in general (eg, ‘hospitals are hotbeds of disease’).

### Understanding transmission process

When asked to identify ways in which they were likely or unlikely to contract COVID-19, participant responses were again varied (figure 3).

The majority of participants correctly identified that transmission of COVID-19 was likely to occur through ‘sneezing/coughing’ (92%), ‘touching a contaminated surface and then touching your eyes, nose or mouth’ (91%) and ‘being physically near someone with COVID-19 for a long period of time’ (90%). Fewer participants (63%) correctly identified that ‘being near someone who had recently been overseas’ made it more likely that they could contract COVID-19. Most participants also correctly identified that you are unlikely to contract COVID-19 from ‘mosquito bite’ (78%) or by ‘touching a package that had come from China’ (64%).

In contrast, 63% of participants thought it was very likely or likely they would contract COVID-19 due to ‘being in a large room with someone for a short period of time’ and 51% thought they had a very likely or likely chance by ‘sitting on a surface where someone with COVID-19 sat’. In a similar response pattern to preventing transmission, there was a lot of uncertainty about whether ‘attending a doctor’s clinic or hospital’ increased your risk of contracting COVID-19 with an even proportion of participants thinking it was unlikely this would increase their risk (48%) and those who thought it would (40%) or were unsure (12%).

### Awareness of COVID-19 symptoms

The majority of participants (90%) identified ‘fever, fatigue and cough’ as indicators of COVID-19 and which, if experienced, would require a person to take further precautions (table 3). However, just over a third of participants (35%) correctly identified ‘fever, fatigue and cough’ as the only indicator (online supplemental table

2). Of concern, 42% of participants thought that being unable to ‘hold your breath for 10s without coughing’ was an indicator of having COVID-19 (table 3).

Information sources
The most frequently reported sources of COVID-19 information were Channels 7, 9 and 10 news (56%), ABC news (43%), and the Australian Government COVID-19 app (31%). Online supplemental table 3 shows the frequency in which each source of information was ranked as first, second or third. Only 23% of participants reported social media as a top 3 source of information and of those did, less than a quarter (24%) of these ranked it as their first source of information.

DISCUSSION
To prevent COVID-19 infections, community members will have to sustain long-term preventive behaviours. To encourage community cooperation, public health officials will need to understand why some individuals do not engage with public health messaging and do not practise COVID-safe preventive behaviours. Therefore, this study had three aims: (1) identify misconceptions about COVID-19 that have the potential to inhibit the uptake of preventive behaviours; (2) examine reasons why individuals hold misconceptions for prevention strategies; and (3) identify the most commonly used sources for acquiring COVID-19-related information. The open-ended responses in this survey give unique information about why individuals hold inaccurate beliefs about preventive behaviours.

The widespread ability to identify the preventative measures of hand hygiene and physical distancing suggests that public health messaging has been effective in communicating prevention strategies to Australians. Although only a minority of participants thought these behaviours were unnecessary or ineffective, this was the major theme arising for people not practising either behaviour. Not knowing this reason for lack of cooperation is a missed opportunity. Using the Capability, Opportunity, Motivation- Behaviour change model (COM-B),14 these behaviours suggest of a lack of motivation and can be directly targeted through public health campaigns.

Almost all participants correctly identified key public health messaging of common symptoms of fever, fatigue and cough and potential transmission practices such as sneezing and coughing and touching contaminated surfaces. This prevention awareness is supported by several other surveys, with between 71% and 93%7 8 10 of participants endorsing correct responses or reporting practising the behaviour.

However, when we examined preventative behaviours not explicitly communicated by public health authorities, the results are more varied. While two-thirds of participants correctly identified that taking antibiotics would not prevent COVID-19, the remaining third thought taking them would prevent COVID-19 or were unsure. Of concern, this result is similar to another
| Behaviour/belief | Major themes for non-compliance (%) | Quotes |
|------------------|------------------------------------|--------|
| **Appropriate behaviours** | Washing hands with soap regularly (n=24; all coded) | Unnecessary or ineffective (37%) |
|                   |                                    | Incorrect or incomplete understanding of transmission (17%) |
| Physical distancing (1.5 m) (n=34; all coded) | Unnecessary or ineffective (50%) |
|                   |                                    | Incorrect or incomplete understanding of transmission (12%) |
| **Inappropriate behaviours** | Taking antibiotics to prevent COVID (n=167; all coded) | Incorrect understanding of antibiotics and treatment for COVID-19 (30%) |
|                   |                                    | Strengthens immune system (29%) |
| Using products like colloidal silver or essential oils (n=179; all coded) | Incorrect or incomplete understanding of transmission and treatment options for COVID-19 (32%) |
|                   |                                    | Strengthens immune system (9%) |

| Behaviour/belief | Major themes for non-compliance (%) | Quotes |
|------------------|-------------------------------------|--------|
| Contentious behaviours | Wearing gloves away from home (n=596; random ½ coded; n=299) | Incorrect or incomplete understanding of transmission (33%) | “Stop infection transmitting” |
| | | Plausible self-protection (18%) | “Pick up any germs from anything or anyone” |
| | | | “To stop me from contracting something and putting it on my face” |
| | | | “Helps prevent touching contaminated surfaces” |
| | | | “They form a barrier to my touching virus-laden surfaces” |
| | Wearing a surgical mask when away from home (n=623; random ½ coded; n=314) | Incorrect or incomplete understanding of transmission (33%) | “To avoid contamination in my mouth” |
| | | Plausible self-protection (23%) | “So you won’t get sick” |
| | | | “It can prevent transmission” |
| | | | “It stops you from touching around your mouth” |
| | | | “Masks help reduce the risk of a person becoming infected by inhaling the virus” |
| | | | “I think it would at least lessen the risk of becoming infected by covering two of the areas the virus can enter the body through” |
| | Staying away from hospitals and health centres (n=872; random ½ coded; n=435) | Infected patients and staff (52%) | “Hospitals are the source of the disease at the moment as hospital is designed for sick people and it is covid-19 era at the moment” |
| | | Explicit concerns of safety and risks (15%) | “Because hospitals and health centres are where other people who could be infected may be” |
| | | Negative beliefs of health services (14%) | It helps to stay away from potential risk |
| | | | Reduce risk of contact with infected people |
| | | | Hospital is risky zone now |
| | | | Those places are where most germs of any description are ideal places to pick up bugs. Go there only in emergency |
An Australian study that reported 35% of participants also thought antibiotics would be effective to prevent or treat COVID-19. When asked for reasons for this misconception, it emerged that most who endorsed antibiotics had poor understanding of how they worked and their effects on viruses and the immune system broadly. Inappropriate use of antibiotics is considered the leading cause of antibiotic resistance. The perception that antibiotics could prevent or treat COVID-19 has the potential to derail ongoing efforts to curb antibiotic use in the community. Further, only half of participants correctly identified that products like colloidal silver or essential oils are not effective in preventing the transmission of COVID-19. Taken together, it appears that many Australians have misconceptions about the effectiveness of pharmaceutical and complementary medicine’s roles in preventing COVID-19. Using behaviour change theory, this suggests a knowledge barrier that can be modified through tailored education and messaging using behaviour change techniques such as information about individual, social and environmental consequences. If people believe these approaches will stop them from contracting the virus, there is legitimate concern they will not practise non-drug interventions such as hand hygiene and physical distancing either now or in the future.

Equally concerning was our finding that at the time of the survey (early May), only 15% of participants were confident that visiting hospitals and health centres were safe. Australian data from the Medical Benefits Scheme appear to reflect this uncertainty, with a 23% drop in face-to-face primary care attendance compared with the average of the same month in the past 5 years. A sharp decline in presentations to emergency departments for reasons other than COVID-19 (eg, stroke, cardiac events and so on) has also occurred internationally. Conversely, the increase in telemedicine (eg, video and phone consultations) in Australia may suggest that although people are physically staying away from attending health services, they are still receiving healthcare through other means. These findings suggest that the emergence of COVID-19 has resulted in significant changes in how healthcare is used. The impact of these

| You have a runny nose and wet cough              | 503 (34) |
| You have had your temperature checked and it is normal | 234 (16) |
| You have a rash                                  | 167 (11) |

Note: Participants were able to choose more than one response.
changes in terms of accessing preventative healthcare services, patient’s health outcomes and healthcare costs is yet to be determined. Two preventative behaviours that were associated with a high degree of uncertainty were wearing gloves and wearing a mask outside of the home. Approximately 40% of participants believed wearing gloves or a mask would prevent transmission of COVID-19, similar to Seale et al’s findings that 50% of surveyed Australians thought their use could prevent COVID-19. This uncertainty surrounding wearing a mask is likely a reflection of the mixed messages that were evident in the media and various public health campaigns used in both Australia and internationally during the early stages of the pandemic. These inconsistent and unclear messages may have contributed to the misconceptions about the effectiveness of masks and how they can reduce the transmission of COVID-19. Although wearing face masks might provide an added benefit to limit the spread of the infection, there has been no public health messages in Australia suggesting wearing gloves is an effective preventive behaviour. While our understanding of virus transmission is still developing, it is likely that, as a respiratory virus, a face mask alone is not sufficient to prevent its transmission. This was not known to many participants in this study, with many thinking that either masks or gloves would be sufficient to stop the spread. Our qualitative coding provided evidence of this. The primary concern of public health authorities is that should people wear masks, they may not practise more effective preventive behaviours such as hand hygiene and physical distancing because they believe masks and gloves are enough to protect them from COVID-19. To improve public health messaging, individual behaviour change techniques such as teaching prompts and cues about how to take masks off and to wash hands after touching a mask, would address the impression that masks alone were sufficient.

Overall, our findings are concordant to those of a recent online survey of over 4000 Australians which also found gaps in understanding. McCaffery et al. found that those with inadequate health literacy and who spoke a language other than English were less able to identify behaviours to prevent infection and experienced more difficulty finding information and understanding public health messaging about COVID-19. This study also identified that, there were higher endorsements of misinformation including negative views of vaccines among the same groups. Given that these views have broader public health implications (decreased vaccine uptake, increased antibiotic resistance), it is critical that we target future messaging to disadvantaged populations such as those with low health literacy and those who are culturally and linguistically diverse to ensure that health consumers are better equipped to make informed decisions with regard to their healthcare.

Finally, to develop effective prevention messages, consideration should be given to where individuals access COVID-19-related information. Counterintuitively, less than a quarter of participants nominated social media platforms in their top three sources of COVID-19 information. Most participants nominated commercial and government sponsored news channels as their top sources. Combining behaviour change techniques in prevention behaviours and promoting these messages in the most accessible and widely used media platforms are critical to ensure continued public cooperation in practicing COVID-safe behaviours.

**Strengths and limitations**
In our sample, 70% of participants were born in Australia. Although this reflects Australian population demographics, results from this survey may not translate to individuals where English is not their primary language. While we assessed readability of the survey, we only informally assessed comprehension when we pilot tested the survey with community members and colleagues. We also did not assess cultural and linguistic diversity of the survey which limits the generalisability of our findings to this group. McCaffery et al. identified that participants whose primary language was not English had poorer understanding of COVID-19 symptoms, were less able to identify behaviours that reduced infection risk and experienced more difficulty understanding government messaging.

Public health messaging not only should ensure translation of messages but also understand the cultural differences that may interfere with practising preventive behaviours. Unlike other Australian surveys, our survey looked beyond quantifying knowledge and attitudes to include qualitative content analyses to identify specific reasons for participants’ misconceptions.

Our sample was balanced for gender and stratified for age. We also had proportionally representative quotas from each Australian state and territory. Despite these efforts, we acknowledge that survey research (with panel providers) has certain biases such as selection and sampling bias, and therefore suggest care when interpreting any results.

**CONCLUSION**
Our results suggest that although clear public messaging about the two key evidence-based prevention behaviours (hand hygiene and physical distancing) is broadly understood, there are still important knowledge gaps around how the disease is prevented, transmitted and its symptoms. Public health messages will need to combat the misconceptions that antibiotics and complementary medicines are effective in prevention and/or treating COVID-19. These beliefs have the potential to impede individuals from practising appropriate and effective behaviours. In the absence of a vaccine or effective drug treatments, our only prevention strategies are non-drug interventions, especially physical distancing and hand hygiene. How do we maintain these behaviours in the long term and how do we initiate other behaviours yet to be seen as critical such as wearing masks, testing when
symptomatic, self-isolating and downloading contact tracing apps? By understanding some of the misconceptions identified in our survey and using the principles of public communication and knowledge translation, we can develop intervention strategies for the longer term.

### Supplementary Table 1. Survey items and scores

| Information source (rank list 3) |
|----------------------------------|
| There are many possible sources to hear or read information about COVID-19. What are your to |
| • Channel 7, 9 or 10 News on TV or online |
| • ABC News on TV or online |
| • SBS News on TV or online |
| • International news |
| • Social media (Facebook, twitter, Instagram) |
| • Other internet sources |
| • Australia government COVID-19 app |
| • Australian Government Whatsapp group/channel |
| • Newspaper/ Magazines (online or in print) |
| • Your doctor |
| • Family and friends |
| • Radio/podcasts |
| • Other (please specify) |

### COVID-19 symptom and behaviour question (randomly ordered, multiple response o
| Which of the following are indicators that would suggest you may have COVID-19 and need to handwashing and staying at home)? |
| • You have a combination of fever, fatigue, and cough |
| • You cannot hold your breath for 10 seconds without coughing |
| • You have had your temperature checked and it is normal |
| • You have a runny nose and wet cough |
| • You have a rash |
**Prevention Questions**

Many people have different ideas about what behaviours are the most likely to prevent you from getting COVID-19 below, if you were to practice it, how much do you agree or disagree that this would prevent you from getting COVID-19?

| Behaviour                                                                 | Rating 1-5 |
|---------------------------------------------------------------------------|------------|
| Wearing a surgical mask when you are away from home                      | 1-5 strongly disagree to strongly agree |
| Wearing gloves when you are away from your home                           | 1-5 strongly disagree to strongly agree |
| Washing your hands with soap regularly especially before and after using the bathroom, eating, or leaving and reentering your home | 1-5 strongly disagree to strongly agree |
| Staying at least 1.5 metres away from people who you don’t live with      | 1-5 strongly disagree to strongly agree |
| Using products like colloidal silver or essential oils                    | 1-5 strongly disagree to strongly agree |
| Taking antibiotics regularly                                              | 1-5 strongly disagree to strongly agree |
| Staying away from hospitals and health centres                            | 1-5 strongly disagree to strongly agree |

**Prompt question for incorrect response**

Why do you think that [incorrect response] would prevent you from getting COVID-19?

**Transmission Questions**

There has been a lot of information shared by experts, the media, family and friends about how you think you are to get COVID-19 from: ?

| Behaviour                                                                 | Rating 1-4 |
|---------------------------------------------------------------------------|------------|
| Someone with COVID-19 sneezing or coughing directly on you                | 1-4 very unlikely to very likely |
| Being in a large room with someone who has COVID-19 for about 5 minutes   | 1-4 very unlikely to very likely |
| Being bitten by a mosquito                                                | 1-4 very unlikely to very likely |
| Sitting on a surface where someone with COVID-19 sat                       | 1-4 very unlikely to very likely |
| Touching a contaminated surface, then touching your eyes, nose or mouth | 1-4 very unlikely to very likely |
| Being physically near someone who has COVID-19 for a long period of time  | 1-4 very unlikely to very likely |
| Touching a mail package that comes from China                              | 1-4 very unlikely to very likely |
| Being at a doctor’s clinic or hospital                                    | 1-4 very unlikely to very likely |
| Being near or talking to someone who has been overseas recently           | 1-4 very unlikely to very likely |
Supplementary Table 2. Number (%) of participants’ correct and incorrect responses to COVID-19 symptoms.

| Response                                           | N (%) |
|----------------------------------------------------|-------|
| Correct response only                              | 521 (35) |
| Correct response + 1 incorrect response            | 453 (30) |
| Correct response + 2 or more incorrect responses   | 369 (25) |
| Incorrect response/s only:                         | 157 (10) |
Supplementary Table 3. Sources of COVID-19 information and their ranking

| Sources                                      | N responses (%) nominated in top 3 | % ranked #1 | % ranked #2 | % ranked #3 |
|----------------------------------------------|------------------------------------|-------------|-------------|-------------|
| Channel 7, 9 or 10 News on TV or online      | 847 (56%)                          | 48%         | 32%         | 21%         |
| ABC News on TV or online                     | 647 (43%)                          | 44%         | 32%         | 24%         |
| Australia government COVID-19 app            | 472 (31%)                          | 44%         | 28%         | 28%         |
| Newspaper/Magazines (online or in print)     | 350 (23%)                          | 29%         | 37%         | 34%         |
| Social media (Facebook, twitter, Instagram)  | 342 (23%)                          | 24%         | 40%         | 37%         |
| Australian Government Whatsapp group         | 286 (19%)                          | 35%         | 34%         | 31%         |
| Family and friends                           | 260 (17%)                          | 23%         | 34%         | 43%         |
| Your doctor                                  | 237 (16%)                          | 24%         | 33%         | 43%         |
| SBS News on TV or online                     | 236 (16%)                          | 19%         | 42%         | 39%         |
| International news                           | 235 (16%)                          | 23%         | 29%         | 49%         |
| Other internet sources                       | 235 (16%)                          | 24%         | 32%         | 44%         |
| Radio/podcasts                               | 193 (13%)                          | 17%         | 40%         | 44%         |
