Abstract

Background

Elderly patients are prone to potentially inappropriate medication use (PIMU); its use have been associated with multiple adverse consequences. As a result, it is crucial to determine the magnitude and factors associated with PIMU. The present study was mainly aimed to determine and assess the magnitude and predictors of potentially inappropriate medications use in elderly patients on follow-up at the chronic care clinic of Jimma medical center.

Methods

A retrospective cross-sectional study was conducted involving 219 patients aged 65 years and above on treatment follow-up. Data was collected using checklist. The 2019 updated American Geriatric Society (AGS) Beers Criteria® and Screening Tool of Older People's Potentially Inappropriate Prescriptions criteria and Screening Tool to Alert Doctors to Right Treatment (STOPP/START) criteria (version 2) were employed to assess PIMU. SPSS IBM (v22) was used for data entry and analysis. Categorical variables were described using frequency and percentage, whereas continuous variables were described using mean with standard deviation (SD) or median with interquartile range (IQR). Logistic regression was conducted to identify predictors of PIMU.

Results

The average number of medications prescribed per patient was 4.0 (IQR = 2.0). At least one PIMU was identified in 182 (83.1%) and 99 (45.2%) patients, based on Beers and STOPP criteria, respectively. Additionally, potential prescription omission (PPO) was observed in 24 (10.9%) patients. The risk of Beers PIMU was increased with age [AOR = 1.21, \( p < 0.001 \)], hypertension [AOR = 4.17, \( p < 0.001 \)], and Polypharmacy [AOR = 14.10, \( p < 0.001 \)], while a decrease in the risk was noted in patients with a diagnosis of ischemic stroke [AOR = 0.133, \( p = 0.01 \)] and asthma [AOR = 0.03, \( p < 0.001 \)]. Using STOPP criteria, hypertension [AOR = 2.10, \( p = 0.04 \)], diabetes mellitus [AOR = 2.26, \( p = 0.04 \)], ischemic heart disease [AOR = 2.84, \( p = 0.04 \)], peripheral neuropathy [AOR = 10.61, \( p < 0.001 \)], and Polypharmacy [AOR = 6.10, \( p < 0.001 \)] significantly increased the risk of PIMU.

Conclusions

Regardless of the screening tool used to assess, the present study revealed PIMU in the large proportion of the participants. Multiple medication use and certain disease condition had increased the probability of PIMU. Thus, it is imperative to use screening tools to review medications prescribed for each hospitalized elderly patients so as to reduce adverse consequences of PIMU.

Introduction

The Global proportion of elderly population (age ≥ 65years) is projected to double from 703 million in 2019 to 1.5 billion in 2050 (1). In Ethiopia, the proportion of elderly population is increasing overtime (2); in 2019 populations aged 65 years and above were 3.52% of the country's total age groups (3). This age groups are usually fragile and more susceptible to drug-related problems as a result of multi-morbidity, polypharmacy, and the physiological changes that affect the kinetics and dynamics of drugs (4–6). As a result, elderly patients are prone to PIMU, which is defined as
using a drug in which the risk of an adverse event outweighs its clinical benefit (7). Thus, medication selection in elderly patients should be made with carefulness (8).

There are multiple screening tools to assist the healthcare providers in selecting medication therapy, and reduce the exposure of the elderly to PIMU. Among them, the AGS Beers Criteria® (9) and STOPP/START are the two most widely used criteria (10). Despite this, there is a growing evidence suggesting therapeutic decisions in older patients are frequently suboptimal or potentially inappropriate (11).

Numerous studies have been conducted to determine the magnitude and factors associated with PIMU using various screening tools. Accordingly, the reported magnitude vary across the studies due to reasons like, the type of screening tool used and others. Using Beers criteria, for instance, in a study from six European hospitals, at least one PIMU was identified in elderly patients ranging from 22.7–43.3% (12). While, studies from United States (13) and Brazil (8) reported PIMU in 24% and 26.9% of the elderly patients, respectively. In Middle East, several studies have reported a high prevalence of PIMU; 57.5% from Saudi Arabia (14), 62.6% and 76.0% Qatar (15, 16), 59.6% from Lebanon (17), and 53.1% from Kuwait (18). In Africa, one study from Nigeria (19) reported a 31% PIMU among elderly patients, while studies from Ethiopia revealed nearly similar magnitude of PIMU; 27.72% from Gondar (20), 23% from Dessie (21), and 28.6% from Tigray (22). Using STOPP/START, a study from Kuwait (18) reported at least one PIMU in 55.7%, while in a study from Gondar (23) PIMU was identified in 61.5% in of elderly patients. Polypharmacy (taking more than or equal to 5 medications) (12, 24), Sex (24, 25), and age (25, 26) were among the independent predictors of PIMU reported in studies.

PIMU poses a multitude of adverse consequences, such as adverse drug events (27–31), increase in healthcare expenditures (32–39), unplanned re-admission (40, 41), and increase in mortality (42–46). As a result, knowing the magnitude and factors that increase the risk of PIMU is important. In Ethiopia, there are limited studies. Therefore, the present study was conducted with a primary aim to determine and assess the magnitude and predictors of potentially inappropriate medications use in elderly patients on follow-up at the chronic care clinic of Jimma Medical Center (JMC).

**Methods**

**The study aim, design, and setting**

The primary aim of this study was to determine and assess the magnitude and predictors of potentially inappropriate medications use in elderly patients on follow-up at the chronic care clinic of Jimma Medical Center. It has also addressed the magnitude of PPOs, the internal agreement, sensitivity and specificity of Beers and STOPP criteria in detecting PIMU. Hospital-based retrospective cross-sectional study design was employed. The study was conducted in JMC chronic care clinic from November 01, 2020 to December 30, 2020. JMC is the only specialized teaching hospital in the South west Ethiopia. It is located in Jimma town, 352 km south west of the capital city, Addis Ababa. JMC is the only teaching and referral hospital in the South Western part of Ethiopia with bed capacity of 620. It provides services for approximately 9000 inpatient and 80000 outpatient clients a year with a catchment population of about 15 million people.

**Population**

**Source population**
The source population were elderly patients on follow-up at the chronic care clinic of JMC.

**Study population**

Elderly patients aged 65 years and above who had a treatment follow-up at the chronic care clinic of JMC for at least six months before the current study were included in the study.

**Sample size and sampling procedure**

Sample size was determined by using a single population proportion formula considering the standard normal variance \((Z) = 1.96\); estimated prevalence of PIMU \((P) = 61.5\%\) from Gondar study (23), and margin of error \((D) =5\%\); total elderly patients aged 65 and above on active follow-up in the setting \((N) = 543\). This had resulted a final sample of \((n) =219\). The participants were selected using systematic random sampling technique.

**Study variables**

**Outcome/dependent variables**

The independent variable of this study was the presence or absence of PIMU (according to Beers criteria, STOPP/START criteria) and PPOs.

**Independent variables**

Socio-demographic variables (age, gender, marital status, residence), clinical and medication-related variables (chronic diseases type and number, Charlson Comorbidity Index score \((CCI)\), medications regimen, number of medications per patient). \(CCI\) score was determined using online Charlson Comorbidity Index-MDCalc (47).

**Data collection tool and procedure**

Data was collected using a checklist developed by extracting relevant variables from related literatures. Two professionals (Bachelor degree graduates in patient-oriented Pharmacy) were employed as data collectors. The data collectors reviewed medical charts of elderly patients, individuals aged 65 years and above as per this study (1), to extract relevant socio-demographic and clinical information, and to establish the list of all most recent medication regimen the patient received during the last visit to the chronic care clinic.

**PIM assessment**

After the completion of data collection, three Clinical Pharmacists (Masters of Clinical Pharmacy graduates) assessed PIMU using the 2019 updated AGS Beers Criteria® (9) and STOPP/START criterion’s (Version 2) (10). Both criteria were used in the previous studies from Ethiopia (20, 48, 49). The AGS Beers Criteria® contains an explicit list of PIMs that are typically best avoided by older adults in most circumstances or under specific situations, such as in certain diseases or conditions. The criteria is comprised of five categories: medications that are potentially inappropriate in most older adults, those that should typically be avoided in older adults with certain conditions, drugs to use with caution, drug-
drug interactions, and drug dose adjustment based on kidney function. On the other hand, the STOPP/START criteria version 2 was applied to identify a list of PIMs (STOPP criteria) and Potential Prescription Omissions (PPOs) (START criteria). STOPP/START is consists of 80 STOPP and 34 START criteria. START criteria contains medications that should be considered for people with certain conditions (PPOs).

**Data quality assurance**

To ensure quality of the data, a brief training was provided to the data collectors on the objective of the study, data collection tool and collection procedure. Prior to the actual data collection, pre-test was done by reviewing eleven (11) medical charts of the elderly participants to check the validity of the checklist for most of the items of the study. PIM assessors were also made more familiar with the 2019 updated AGS Beers Criteria® and STOPP/START criteria (Version 2) for assessing PIMU.

**Data processing and analysis**

Data entry, clearance and analysis was carried-out using SPSS Version 22.0. Frequency and percentage were calculated for categorical variables. For continuous variables, normality test was done using Shapiro-wilk test; data was considered normally distributed when the \( p \)-value of the test is not < 0.05. Then, parametric (normally distributed) data were presented using mean, whereas median was calculated for non-parametric variables. Patients’ diagnosis were grouped according to the categories listed in the International Classification of Diseases-11 (ICD11) (50). A minimal threshold of five medications was used to declare poly-pharmacy (51). Spearman's rho (\( r_s \)) correlation test was conducted to check the presence and strength of correlation between the number of PIMs identified using Beers criteria and STOPP criteria, while Cohen’s kappa (\( \kappa \)) test was conducted to determine the reliability between the two PIM raters used in this study (Beers criteria and STOPP criteria). The sensitivity and specificity of the two PIM raters were also checked. Using a dichotomous variable to represent the presence or absence of PIM (0 = no PIM; 1 = PIM), a binary logistic regression analysis was conducted after checking cell adequacy of each categorical variables using a Chi-square test. Variables with a \( p \)-value < 0.25 were recruited for multivariable logistic regression analysis. Hosmer and Lemeshow Test was conducted and both models of logistic regression indicated a good fit (\( P>0.05 \)). In all statistics, a cut-off \( p \)-value < 0.05 was considered to declare statistical significance of the association.

**Results**

**Overview of the study**

This study involved ambulatory patients (n=219) aged ≥ 65 years old on follow-up at the chronic care clinic for at least 6-months. The average age of the study participants was 70 (IQR=9), and nearly two-thirds (n=143; 65.3%) of the participants were male (Table 1).

Table 1: Sociodemographic information of the participants.
Sociodemographic information

|                |       |
|----------------|-------|
| Age            | 70 (IQR=9) |
| Sex            |       |
| Male           | 143 (65.3%) |
| Female         | 76 (34.7%) |
| Residence      |       |
| Urban          | 106 (48.4%) |
| Rural          | 113 (51.6%) |

Clinical and related information

All of the participants had at least one chronic disease. Disease of the circulatory system were the most commonly class of diseases, hypertension (n=127; 58%) being the predominant of all (Table 2).

Medication-related information and PIMU

The total number prescribed medications were 902; on average each patients were prescribed with 4.0 (IQR=2.0) medications. Overall, 93.0 (42.5%) patients were on polypharmacy. PIMU was identified in 182 (83.1%) and 99 (45.2%) patients, according to Beers and STOPP criteria, respectively. Furthermore, 24 (10.9%) patients had at least one PPO (Table 3).

Table 3: Medication-related information and the magnitude of PIMU identified in the study.
Medication-related information

| Description                                           | Value               |
|-------------------------------------------------------|---------------------|
| Medication prescription per patient, Median (IQR)     | 4.0 (2.0)           |
| Patients on Polypharmacy                              | 93 (42.5%)          |

| According to the STOPP criteria                       |                     |
| Total PIMs                                           | 128                 |
| Patients on PIMs                                      | 99 (45.2%)          |
| PIMs per patient, Mean (± SD)                         | 0.6 (±0.76)         |
| One PIM                                               | 77 (35.2%)          |
| Two PIMs                                              | 15 (6.8%)           |
| Three PIMs                                            | 7 (3.2%)            |
| PPO according to the START criteria                   |                     |
| Total PPOs                                            | 25                  |
| Patients with PPOs                                    | 24 (10.9%)          |

PIMs-Potentially inappropriate medications, PPO- Potential Prescription Omissions, STOPP-Screening Tool of Older People's Potentially Inappropriate Prescriptions, START- Screening Tool to Alert Doctors to Right Treatment.

According to Beers criteria, Aspirin (n=71; 24.9%) was the most commonly prescribed PIM which needs a cautious use in those aged 70 years and above followed by Hydrochlorothiazide (n=50; 17.5%) again with cautious use recommendation (Table 4).

Using STOPP criteria, the most commonly prescribed PIM was Amitriptyline (n=38; 29.7%) followed by furosemide (n=27; 21%) and Glibenclamide (n=18; 14%). Whereas, the most commonly omitted medication observed were ACE inhibitors (58.3%), followed by beta blockers (29.2%) and Aspirin (4.2%) (Table 5).

Table 5: Specific PIMs and PPOs according to STOPP/START criteria.
| PIM | Drug class | Frequency (%) |
|-----|------------|---------------|
| **Using STOPP criteria**                                                                 |
| Amitriptyline | TCA anti-depressants | 38 (29.7) |
| Furosemide | Loop diuretics | 27 (21) |
| Glibenclamide | Sulphonyl urea | 18 (14) |
| Enalapril | ACEIs | 12 (9.4) |
| Hydrochlorothiazide’s | Thiazide diuretics | 10 (7.8) |
| Aspirin | Anti-platelet | 8 (6.25) |
| Metformin | Biguanides | 4 (3.1) |
| Clopidogrel | Anti-platelet | 3 (2.3) |
| Digoxin | Digitalis glycosides | 2 (1.6) |
| Tramadol | Narcotic analgesics | 2 (1.6) |
| Metoprolol | Beta blocker | 2 (1.6) |
| Indomethacin | NSAID | 1 (0.8) |
| Meloxicam | NSAID | 1 (0.8) |
| **Total** | | **128 (100)** |
| **Using START criteria (PPOs)**                                                          |
| ACEIs | ACEIs | 14 (58.3) |
| Beta blockers | Beta blockers | 7 (29.2) |
| Aspirin | Anti-platelet | 1 (4.2) |
| Non TCA anti-depressants | Non-TCA antidepressants | 1 (4.2) |
| Regular inhaled beta 2 agonist | Regular inhaled beta 2 agonist | 1 (4.2) |

ACEIs-Angiotensin converting enzyme inhibitors, TCA-Tricyclic antidepressants, NSAID-Non-steroidal anti-inflammatory drug.

**Correlations, reliability, sensitivity, and specificity of PIM raters used in this study**

The two PIM raters used in this study i.e., Beers and STOPP criteria, had a minimal and inadequate agreement in rating PIMs ($\kappa = 0.22$, 95%CI: 0.15, 0.31, $p< 0.001$). Additionally, the number of PIMs identified using these two criteria were also fairly correlated with each other ($r_s = 0.48$, $p< < 0.001$). Presuming STOPP criteria as a
test result, it had a sensitivity of 52.20% and specificity of 89.19%, whereas taking Beers criteria as a test result, the sensitivity and specificity of Beers criteria was 96.0% and 27.5%, respectively.

Factors associated with PIMU based on Beers’ criteria

On binary logistic regression, age (p < 0.001), frequency of outpatient visits in the last six months [four times (p= 0.03) and six times (p= 0.02)], hypertension (p < 0.001), asthma (p= 0.02), epilepsy (p < 0.001), and Polypharmacy (p < 0.001) were significantly associated with Beer’s PIM. A total of eight variables had a p-value < 0.25 and were recruited for multivariate logistic regression. Upon conducting a multivariate logistic regression, age [AOR=1.21, 95%CI: 1.09, 1.34, p < 0.001], hypertension [AOR=4.17, 95%CI: 1.51, 11.56, p < 0.001], ischemic stroke [AOR=0.133, 95%CI: 0.03, 0.64, p= 0.01], asthma [AOR=0.03, 95%CI: 0.00, 0.39, p < 0.001], and polypharmacy [AOR=14.10, 95%CI: 2.61, 76.38, p < 0.001] were independently associated with Bee’s PIM (Table 6).

Factors associated with PIMU based on STOPP criteria

On binary logistic regression, the variables: above two times outpatient visits in the last 6-months, number of chronic diseases, hypertension, diabetes mellitus, ischemic heart disease, peripheral neuropathy, and Polypharmacy were significantly associated with PIM use based on STOPP criteria. Running multiple logistic regression, hypertension [AOR=2.10 48, 95%CI: 1.04, 4.29, p=0.04], diabetes mellitus [AOR=2.26, 95%CI: 1.037, 4.91, p=0.04], ischemic heart disease [AOR=2.84, 95%CI: 1.05, 7.67, p=0.04], peripheral neuropathy [AOR=10.61, 95%CI: 3.08, 36.54, p<0.001], and Polypharmacy [AOR=6.10, 95%CI: 3.08, 14.59, p<0.001] significantly increased the risk of using PIM (Table7).

Discussion

This was a retrospective cross-sectional study conducted involving 219 elderly patients on follow-up at the chronic care clinic of a specialized teaching medical center in Ethiopia. The main objective of this study was to determine the magnitude and factors associated with PIMU based on Beers and STOPP criteria. Accordingly, 83.2% and 45.2% of the patients had at least one PIM based on Beers and STOPP criteria, respectively. Additionally, 24 (10.9%) patients had at least one PPO.

In the present study, the magnitude of PIMU based on Beers criteria was higher than some previous studies. The magnitude of PIMU was 50.0% in a study from USA (52), 26.9% from Brazil (8), and 30.5% from Irish (24). In India, studies had reported PIMU prevalence of 23.5% (53), 24.6% (26), and 61.9% (25), while in studies from middle east, PIMU was reported in 53.1% from Kuwait (18); 61.0% from Saudi Arabia (27); 45.2% from Lebanon (54); 62.6% (15) and 76.0% (16) from Qatar. In Africa, studies are limited. One study from Nigeria (19) reported a 31% of PIMU, while in Ethiopia, studies from Tigray (22); Gondar (20), and Dessie (21) reported PIMU in 28.6% 27.7%, and 23% of the elderly patients, respectively. The discrepancy in the magnitude of PIMU could be due to many factors. For instance, Beers criteria are the commonly used guidelines to manage and improve the care of individuals aged 65 years and older in healthcare settings (9). Contrary to this, our study setting lack the privilege of flagging potentially inappropriate medication list for extra caution which will made prescribers to comfortably rely on the same medication for years without the concern of safety. Additionally, adopting different version of Beers criteria in the previous studies (AGS Beers Criteria 2012 and 2015) as compared to the present study (AGS Beers Criteria 2019) might also explain the difference in the magnitude of PIMU. Furthermore, the difference in the data collection method (chart review versus prospective) employed across those studies might have also contributed to the variation in the magnitude of PIMU.
Based on STOPP criteria, at least one PIMU was identified in 45.2% of the elderly patients in our study. This indicates nearly half of our participants were taking medication which could be harmful to their health. Using the same criteria, studies from Gondar (23) and Kuwait (18) reported at least one PIMU in 61.5% and 55.7% of elderly out patients, respectively. These magnitudes are higher than our study finding. The Gondar study was a prospective study which is a better design to track all medication used by the patient, and the Kuwait study was also a prospective study and the investigators employed both medical electronic and non-electronic records to exhaustively access the patients’ prescribed medications and other information. In our case there is only non-electronic records (patient medical chart) to access prescribed medications and other information which might have some incomplete medication list. Besides, limited availability of some medications in Ethiopia could have contributed to the less magnitude of PIM identified in our study.

In the present study, as the age of the patient increased, the risk of Beers PIMU was also observed to increase \([p < 0.001]\). Based on either Beers or STOPP criteria, hypertension and taking polypharmacy were significantly increased the probability of PIMU. Taking polypharmacy had increased the risk of PIMU by more than fourteen \([p < 0.001]\) and six times \([p < 0.001]\) based on Beers and STOPP criteria, respectively. Being hypertensive increased the likelihood of PIMU by more than four times \([p < 0.01]\) and two times \([p < 0.04]\) based on Beers and STOPP criteria, respectively.

Similarly in the previous studies, taking polypharmacy (14, 55, 56), advanced age (25, 56), and hypertension (57) were reported as a significant predicting factors for PIMU. As the age advance, metabolic changes and decreased drug clearance, and increased drug-drug interactions are expected (58). On the other hand, simultaneous use of multiple medications probably increases the risk of drug-drug, drug-disease interactions as well as diverting clinician’s attention to provide quality care, which in turn increases the likelihood of prescribing PIMs. Contrary to our expectations, in the current study, patients with ischemic stroke \([p = 0.01]\) and asthma \([p < 0.001]\) were associated with lower Beer’s PIMU. In our study, the proportion of the patients with these disease conditions were small which could be a possible justification.

According to STOPP criteria, increased likelihood of PIMU was also observed in patients with ischemic heart disease \([p < 0.04]\), diabetes mellitus \([p < 0.04]\), and peripheral neuropathy \([p < 0.001]\). Other studies had also reported similar predictors (14-16). Surprisingly, age was not a significant predictor of PIMU based on STOPP criteria. As chronic morbidities are expected to increases with age, so does the risk of multiple comorbidities and multiple medication use.

**Conclusion**

In the present study, PIMU was identified in large proportion of the participants. Multiple medication use and certain comorbidities had increased the probability of PIMU. We recommend the use of screening tools for reviewing medications prescribed for each hospitalized elderly patients to reduce the adverse consequences related to PIMU.

**Declarations**

**Ethical approval and consent to participate**

The study was ethically approved by the ethics committee of Jimma University school of Pharmacy (Ref.no: SP/200/2013). Subsequently, permission was granted from JMC to access medical records. Raw data extracted from the patient medical chart were held confidential during the data collection and afterwards. Informed consent requirement was waived by the ethics committee of Jimma University school of Pharmacy as the study was done through chart review. All methods were carried out in accordance with the approved protocol.
Consent for publication

Not applicable.

Availability of data and data materials

The datasets supporting the conclusion of this article are included within the article (and its additional file(s)).

Competing interest

The authors declare that they have no competing interests.

Funding

No funding has been secured for this study.

Acknowledgements

We would like to thank Jimma University school of Pharmacy for allowing us to conduct this study. Our gratitude also extends to the patient data room staffs of JMC.

Authors' contribution

B.T, M.T, D.D, and M.A designed and performed the research, analyzed, interpreted the data, wrote and evaluated the manuscript. All authors read and accepted the final manuscript.

**Table 2**: Clinical and related information of the study participants.
## Clinical and related information

### Outpatient visits in the last 06 months

| Frequency | Count | Percentage |
|-----------|-------|------------|
| 1-2 times | 34    | 15.5%      |
| 3 times   | 99    | 45.2%      |
| 4 times   | 37    | 16.9%      |
| 5 times   | 18    | 8.2%       |
| 6 times   | 31    | 14.2%      |

### Number of chronic diseases

| Number of Diseases | Count | Percentage |
|--------------------|-------|------------|
| One                | 81    | 37.0%      |
| Two                | 97    | 44.3%      |
| ≥ Three            | 41    | 18.7%      |

### CCI, mean ± SD

3.6 ± 1.1

### Disease of the circulatory system

| Condition                                      | Count | Percentage |
|------------------------------------------------|-------|------------|
| Hypertension                                   | 127   | 58%        |
| Ischemic heart disease                         | 30    | 13.7%      |
| Ischemic stroke                                | 21    | 9.6%       |
| Heart failure                                  | 16    | 7.3%       |
| Hypertensive heart disease                     | 15    | 6.8%       |
| Ischemic dilated cardiomyopathy                | 15    | 6.8%       |
| Atrial fibrillation                            | 8     | 3.7%       |
| Others                                         | 8     | 3.7%       |
| Chronic rheumatic valvular heart disease       | 6     | 2.7%       |
| Certain infectious and parasitic diseases       | 5     | 2.5%       |

### Endocrine, nutritional and metabolic diseases

| Condition                   | Count | Percentage |
|-----------------------------|-------|------------|
| Diabetes mellitus           | 69    | 31.5%      |
| Goiter                      | 2     | 0.9%       |
| Thyrotoxicosis              | 1     | 0.5%       |

### Diseases of the nervous system

| Condition                        | Count | Percentage |
|----------------------------------|-------|------------|
| Peripheral neuropathy            | 25    | 11.4%      |
| Epilepsy                         | 13    | 5.9%       |
| Hemiparesis                      | 6     | 2.7%       |
| Others                           | 4     | 2%         |

### Disease of the respiratory system

| Condition                                  | Count | Percentage |
|--------------------------------------------|-------|------------|
| Asthma                                     | 8     | 3.7%       |
| Chronic obstructive pulmonary disease      | 7     | 3.2%       |
| Interstitial lung disease                  | 1     | 0.5%       |

### Disease of the digestive system

| Condition                                | Count | Percentage |
|------------------------------------------|-------|------------|
| Dyspepsia                                | 7     | 3.2%       |
| Chronic liver disease                    | 1     | 0.5%       |

### Disease of the genitourinary system

| Condition                                | Count | Percentage |
|------------------------------------------|-------|------------|
| Benign prostatic hyperplasia             | 3     | 1.4%       |
| Chronic kidney disease                   | 2     | 0.9%       |

### Disease of the blood and blood-forming organs

| Condition                                | Count | Percentage |
|------------------------------------------|-------|------------|
| Iron deficiency anemia                   | 1     | 0.5%       |

### Disease of the eye and adnexa

| Condition                                | Count | Percentage |
|------------------------------------------|-------|------------|
| Glaucoma                                  | 1     | 0.5%       |
