Through this article, we show that the amplitudes for the $b\bar{b} \rightarrow ZH$ in the presence of bottom-Higgs Yukawa coupling can be constructed, up to a few anomalous diagrams, solely from a set of vector form factors of properly grouped classes of diagrams. Thereby, we can completely bypass the subtle issues involving the chiral quantity $\gamma_5$. In the second part, we demonstrate that while computing the $q\bar{q} \rightarrow ZH$ amplitudes in Higgs effective field theory employing a non-anticommuting $\gamma_5$ in dimensional regularization, we need to introduce a four-point effective composite operator to the renormalized Lagrangian in order to retain the physical properties of the amplitude.
1. Introduction

VH events play an important role in the exploration of the Higgs physics at the Large Hadron Collider (LHC). Understanding the fundamentals of the electroweak symmetry breaking from direct experiment is of prime importance for which a detailed exploration is underway. The recent observation [1, 2] of the Higgs boson decaying to a pair of bottom quarks gets its primary contribution from the VH channel. Due to its high phenomenological importance, there has been a significant number of computations available in the literature aiming to make the theoretical predictions more precise [3–12].

In this article, we consider the two-loop QCD corrections for the production of the scalar Higgs ($H$) in association with the $Z$ boson through bottom quark annihilation in presence of bottom-Higgs non-zero Yukawa coupling. We show [13] that the non-anomalous part of the axial amplitude can be obtained by completely bypassing an explicit computation of the axial part. This means we can completely avoid encountering the subtle issues involving the chiral quantity $\gamma_5$.

In the second part of the article, we show that while computing the two-loop QCD corrections to the production of $HZ$ in Higgs effective field theory (HEFT), we are bound to encounter a striking phenomenon. In particular, we find that the amplitude computed using non-anticommuting $\gamma_5$ in dimensional regularization fails to exhibit the expected chiral Ward identity and universal infrared behaviour. To restore these properties, we need to introduce an amendment involving four-point effective operator to the renormalized Lagrangian. On the other hand, if we apply an anticommuting $\gamma_5$, we do find the amplitudes fulfil all the expected properties.

2. Axial vector form factors from vector counterparts for $b\bar{b} \rightarrow ZH$ amplitudes

We consider the production of massive $Z$ and scalar Higgs ($H$) bosons through bottom ($b$) quark annihilation:

\[ b(p_1) + \bar{b}(p_2) \rightarrow Z(q_1) + H(q_2). \]
On the $ZH$ amplitudes at two loop in QCD

The quantities within the parentheses denote the corresponding four-momentum satisfying $p_1^2 = p_2^2 = 0, q_1^2 = m_Z^2, q_2^2 = m_H^2$, where $m_Z$ and $m_H$ are respectively the masses of $Z$ and $H$ bosons. We define the Mandelstam variables as $s \equiv (p_1 + p_2)^2, t \equiv (p_1 - q_1)^2, u \equiv (p_2 - q_1)^2$ with $s + t + u = q_1^2 + q_2^2 = m_Z^2 + m_H^2$. We keep a non-zero $b\bar{b}H$ Yukawa coupling $\lambda_b$, otherwise $b$ quark is treated as massless. The top quark is considered as infinitely heavy and hence we work in $n_f = 5$ massless flavor limit. In this article, we compute the two-loop scattering amplitude in QCD for the non-Drell-Yan type diagrams, as shown in figure 1. We parameterize the scattering amplitude as

$$M = \lambda_b \bar{\nu}(p_2) \Gamma^\mu u(p_1) \varepsilon^\mu_\gamma(q_1)$$

$$= \bar{\nu}(p_2) \left( \lambda_b g_{V,b} \Gamma^\mu_{vec} + \lambda_b g_{A,b} \Gamma^\mu_{axi} \right) u(p_1) \varepsilon^\mu_\gamma(q_1)$$

$$= \lambda_b g_{V,b} M_{vec} + \lambda_b g_{A,b} M_{axi}.$$

(2)

The symbol $\Gamma^\mu \equiv g_{V,b} \Gamma^\mu_{vec} + g_{A,b} \Gamma^\mu_{axi}$ represents a matrix in the spinor space with the vector and axial vector couplings $g_{V,b}$ and $g_{A,b}$, respectively. $\varepsilon^\mu_\gamma$ is the polarization vector of the $Z$ boson.

Our goal is to demonstrate an elegant formalism [13] that allows us to get the non-anomalous axial contributions by bypassing the explicit computation. In particular, we show how to get this contribution from the vector part of the amplitude.

![Figure 1: Leading order Feynman diagrams that involve the bottom-Higgs Yukawa coupling.](image)

![Figure 2: Sample diagrams where the Higgs or Higgs+$Z$ bosons couple to a quark loop.](image)

We employ an anticommuting $\gamma^{AC}_5$ in $D = 4 - 2\epsilon$ dimensions. Note that the set of diagrams, as shown in figure 2, where either Higgs or Higgs+$Z$ bosons get radiated from closed fermionic loop identically vanish owing to the trace over an odd number of $\gamma$ matrices. Therefore, at two-loop we get non-zero contributions only from those diagrams where $Z$ boson couples to the open $b$ quark line and consequently the $\gamma^{AC}_5$ in $\Gamma^\mu_{axi}$ can be anticommutated next to an external $b$ quark spinor. This non-zero contribution is categorised as class-$ZH$ and class-$HZ$ corresponding to the QCD corrections to the tree level diagrams (A) and (B), respectively in figure 1. The reason we perform this separation is because of the presence of a chirality flipping Yukawa interaction on $b$. 

3
quark line a relative negative sign gets generated between these two class of contributions when we
push the $\gamma_5^{AC}$ next to the same external $b$ quark spinor. This is also the reason why the vector
and non-anomalous axial form factors are not identical to each other. Let us focus solely on the vector
part of the amplitude and decompose it as

$$
M_{vec} = \bar{v}(p_2) \left( \Gamma_{ZH}^\mu + \Gamma_{HZ}^\mu \right) u(p_1) \epsilon^*_\mu(q_1),
$$

where we denote the scalar form factors by $F_{i,X}$. We can calculate the set of projectors \[12, 14\]
for this aforementioned tensor decomposition. In the absence of axial coupling, the above four
tensorial structures are linearly independent and complete in $D$ dimensions for $M_{vec}$ irrespective
of the QCD loop order.

By applying the projectors we get the scalar form factors without encountering any subtlety
related to the $\gamma_5$. The renormalisation of the bare form factors is also straightforward as dictated by
the vector part of the amplitude. The complete vector form factors $F_{i,vec}$ are obtained through

$$
F_{i,vec} = F_{i,ZH} + F_{i,HZ} \quad \text{for } i = 1, 2, 3, 4.
$$

Now let us come back to the axial part. We can decompose it into non-anomalous or non-singlet
and anomalous or singlet contributions

$$
M_{axi} = M_{axi(ns)} + M_{axi(s)}.
$$

Similar to the vector part, we perform a Lorentz covariant decomposition of the non-singlet part of
the amplitude by applying $\gamma_5^{AC}$ in $D$ dimensions which reads as

$$
M_{axi(ns)}^\mu = \bar{v}(p_2) \left( F_{1,axi(ns)} p_1^\mu + F_{2,axi(ns)} p_2^\mu + F_{3,axi(ns)} q_1^\mu + F_{4,axi(ns)} \gamma^\mu q_1 \right) \gamma_5 u(p_1).
$$

We find that the aforementioned scalar form factors can be obtained from the vector parts through

$$
F_{i,axi(ns)} = F_{i,HZ} - F_{i,ZH}.
$$

The reason behind the appearance of the relative negative sign is discussed in the text above
(3). In ref. \[12\], we explicitly computed the axial form factors by treating $\gamma_5$ appropriately. While
comparing the ultraviolet renormalized finite remainders, we find a perfect agreement. Note that the
ultraviolet renormalization that is required to obtain (7) is identical to that of the vector counterpart.
The results of the partial form factors $F_{i,ZH}$ and $F_{i,HZ}$ can be found from the ancillary files of
ref. \[13\]. The singlet part of the amplitude can not be restored by this method, it must be computed
explicitly by applying a non-anticommuting $\gamma_5$ prescription, as demonstrated in ref. \[12\].

3. **A pitfall in $q\bar{q} \to ZH$ amplitudes in Higgs effective field theory**

In this section, we consider the production of $ZH$ through quark annihilation within the
framework of Higgs effective field theory where the top quark loop in integrated out by treating it
infinitely heavy. In figure 3, we show some sample diagrams at the leading order. By decomposing
On the $ZH$ amplitudes at two loop in QCD

The amplitude $M$ into a vector ($M_{\text{vec}}$) and axial ($M_{\text{axi}}$) parts, we can perform a Lorentz covariant decomposition in $D$ dimensions as

$$
M_{\mu}^{\text{vec}} = \bar{v}(p_2) \left( \mathcal{F}_{1,\text{vec}} q_1 p_1^\mu + \mathcal{F}_{2,\text{vec}} q_1 p_2^\mu + \mathcal{F}_{3,\text{vec}} q_1 q_1^\mu + \mathcal{F}_{4,\text{vec}} \gamma^\mu \right) u(p_1),
$$

$$
M_{\mu}^{\text{axi}} = \bar{v}(p_2) \left( \mathcal{F}_{1,\text{axi}} q_1 p_1^\mu + \mathcal{F}_{2,\text{axi}} q_1 p_2^\mu + \mathcal{F}_{3,\text{axi}} q_1 q_1^\mu + \mathcal{F}_{3,\text{axi}} \gamma^\mu \right) \gamma_5 u(p_1). \tag{8}
$$

The axial part consists of the non-singlet, $M_{\mu}^{\text{axi(nns)}}$, and singlet, $M_{\mu}^{\text{axi(s)}}$, contributions. While focusing on the non-singlet part and performing the calculation employing an anticommuting $\gamma_5$, we find that the finite remainders of the form factors satisfy

$$
\mathcal{F}_{i,\text{axi(nns)}}^{(l)} = \mathcal{F}_{i,\text{vec}}^{(l)}, \quad i = 1, 2, 3, 4, \quad l = 1, 2, \tag{9}
$$

with

$$
\mathcal{F}_{i,\text{va}} = \sum_{l=1}^{\infty} d_{s}^{(l+1)}(\mu_R) \mathcal{F}_{i,\text{va}}^{(l)}, \quad \text{va} = \text{vec,axi(nns)}. \tag{10}
$$

We denote the strong coupling constant at the renormalization scale $\mu_R$ by $a_s(\mu_R) \equiv \alpha_s(\mu_R)/(4\pi)$. The identity in (9) leads to the expected chiral invariance. Our method of computation is presented in detail in refs. [12, 13]. Instead of applying the anticommuting (AC) $\gamma_5$, if we employ a prescription of non-anticommuting (NAC) $\gamma_5$, we encounter the violation of the above identity.

In dimensional regularization, we can define a NAC $\gamma_5$ as [15, 16]

$$
\gamma_5 = -\frac{i}{4!} \epsilon_{\mu\nu\rho\sigma} \gamma^\mu \gamma^\nu \gamma^\rho \gamma^\sigma, \tag{11}
$$

where the Lorentz indices of the Levi-civita symbol $\epsilon_{\mu\nu\rho\sigma}$ are treated in D dimensions [17]. Due to this definition, we need an additional care [17–19] while performing the ultraviolet renormalization to ensure the restoration of the Ward identity. However, surprisingly we find that the expected Ward identity gets violated while comparing the finite remainders ($\epsilon \to 0$). Although the LO vertex finite remainders are identical to the corresponding quantities obtained using AC $\gamma_5$, the axial ones are not. In particular, we discover that

$$
\mathcal{F}_{i,\text{axi(nns)}}^{(1),\text{NAC}} = \mathcal{F}_{i,\text{vec}}^{(1)}, \quad i = 1, 2, 3, \tag{12}
$$

$$
\mathcal{F}_{4,\text{axi(nns)}}^{(1),\text{NAC}} \neq \mathcal{F}_{4,\text{vec}}^{(1)}. \tag{12}
$$

This immediately implies the violation of the Ward identity even at the LO level

$$
q_{1,\mu} M_{\mu}^{\text{NAC}} \neq 0. \tag{13}
$$

Figure 3: Sample diagrams at the leading order in HEFT. The external curly and dotted lines respectively denote the $Z$ and $H$-bosons.
We find that the Ward identity can be restored if we introduce an amendment term of the form
\[
\mathcal{J}^{\mu,\text{NAC}} = Z_h^h(a_s) \mathcal{C} \left( \bar{v}(p_2) \left[ \gamma^\mu \gamma_5 \right]_L u(p_1) \right)
\]
(14)
to the renormalized Lagrangian. This amendment term can be visualised as a four-point local composite operator as shown in figure 4. The constant factor \( C = a_s (-4C_F) C_H / v \) absorbs the overall \( a_s^2 \) of the LO amplitude. \( C_F \) is the quadratic Casimir of SU\((n_c)\) gauge group in fundamental representation. \( C_H \) and \( v \) are respectively the Wilson coefficient and vacuum expectation value of the scalar Higgs. The symbol \([ ]_L\) means the quantity is renormalized according to the Larin scheme \([17, 18]\). We introduce an additional renormalization constant \( Z_h^h(a_s) = 1 + O(a_s) \) which should be determined order by order in perturbation theory. By performing an explicit computation to the next-to-leading order, we find \([13]\) that the corresponding non-singlet contribution as
\[
Z_{h,ns}^h(a_s) = 1 + a_s \left( \frac{-\beta_0}{\epsilon} + \frac{107}{18} C_A - 7 C_F - \frac{1}{9} n_f \right) + O(a_s^2),
\]
(15)
and the singlet as
\[
Z_{h,s}^h(a_s) = 1 + a_s \left( -\frac{3}{2} \frac{1}{\epsilon} - \frac{3}{4} \right) + O(a_s^2).
\]
(16)
We denote the quadratic Casimir in adjoint representation of SU\((n_c)\) gauge group by \( C_A \), the number of active light quark flavor by \( n_f \) and the leading coefficient of QCD \( \beta \) function by \( \beta_0 = 11 C_A / 3 - 2 n_f / 3 \).

To summarise, the renormalised effective Lagrangian with a non-anticommuting \( \gamma_5 \) for computing the \( q\bar{q} \to ZH \) in HEFT can be written as
\[
\mathcal{L}_R = \left[ \mathcal{L}_c + \mathcal{L}_{\text{eff}} \right]_R + \kappa Z_{h}^h(a_s) \mathcal{C} \left( \bar{q}(x) \left[ \gamma^\mu \gamma_5 \right]_L q(x) \right) Z_H(x) H(x),
\]
(17)
where \( \kappa_{ns} = c_t g_{A,q} \) and \( \kappa_s = c_t g_{A,b} \). The second term is the new amendment which does not arise while computing non-anomalous set of diagrams employing the anticommuting \( \gamma_5 \) scheme.

4. Conclusions

Through this article, we demonstrate two salient features of the \( ZH \) amplitudes through quark annihilation. (1) The non-singlet (non-anomalous) part of the axial form factors of the \( b\bar{b} \to ZH \) can be computed from a set of vector form factors, thus by completely bypassing the handling of \( \gamma_5 \). (2) While computing the \( q\bar{q} \to ZH \) amplitudes in HEFT by employing a non-anticommuting \( \gamma_5 \) in dimensional regularization, we need to introduce a four-point effective composite operator to the renormalized Lagrangian in order to fulfil the expected Ward identity.
