A dominant mutation in the ITM2B/BRI2 gene causes familial Danish dementia (FDD) in humans. To model FDD in animal systems, a knock-in approach was recently implemented in mice expressing a wild-type and mutant allele, which bears the FDD-associated mutation. Since these FDDKI mice show behavioural alterations and impaired synaptic function, we characterized their synaptosomal proteome via two-dimensional differential in-gel electrophoresis. After identification by nanoliquid chromatography coupled to electrospray-linear ion trap tandem mass spectrometry, the differentially expressed proteins were classified according to their gene ontology descriptions and their predicted functional interactions. The Dlg4/Psd95 scaffold protein and additional signalling proteins, including protein phosphatases, were revealed by STRING analysis as potential players in the altered synaptic function of FDD KI mice. Immunoblotting analysis finally demonstrated the actual downregulation of the synaptosomal scaffold protein Dlg4/Psd95 and of the dual-specificity phosphatase Dusp3 in the synaptosomes of FDD KI mice.

1. Introduction

Familial Danish Dementia (FDD) is a neurodegenerative disease characterized by early cataracts, deafness, progressive ataxia, and dementia. Patients with FDD show diffuse brain atrophy and widespread amyloid angiopathy. In FDD, neurofibrillary tangles (NFTs) are the major histological finding in the hippocampus [1–3]. FDD is an autosomal dominant disease caused by the accumulation of the amyloidogenic C-terminal 34 amino acid peptide of BRI2. BRI2, a product of the ITM2B/BRI2 gene, is a type II transmembrane protein of unknown function. Physiologically, BRI2 is cleaved at the C-terminus by furin endoprotease, producing a 23-amino acid soluble C-terminal fragment [2]. FDD is caused by a decamer duplication in the 3′ region of the ITM2B/BRI2 gene. This mutation produces a longer 34 amino acid C-terminal fragment that accumulates as amyloid [4, 5].

FDD and Alzheimer’s disease (AD) share neuropathological features, including amyloid deposition and neurodegeneration in the central nervous system [6–8]. The mature form of BRI2 is able to reduce accumulation of the Aβ peptide [9–12] while APP catabolites, including Aβ, were significantly increased in the brain of FDD patients [13]. The interaction between these two amyloidogenic proteins (BRI2 and APP) can be relevant for the design of new therapeutic strategies for FDD and AD.

To model FDD pathogenesis in animals, several mouse lines have been generated and analyzed so far [14], which include transgenic mice expressing wild-type [15] or mutant [16, 17] BRI2 proteins, as well as ITM2B/BRI2 gene knock-out mice [10] or ITM2B/BRI2 knock-in mutant mice [18]. The transgenic mice overexpressing the FDD-associated mutation of human ITM2B/BRI2 partially recapitulated the main histopathological features of FDD; they indeed developed cerebral amyloid angiopathy, parenchymal amyloid deposition, and neuroinflammation [14, 16]. Age-dependent deposition of Danish amyloid peptide was also observed in the brain of a second transgenic model, with associated angiopathy and microhemorrhage, neuritic dystrophy, and neuroinflammation [17]. In this model, deposition of
the Danish peptide also accelerated Tau pathology in a double transgenic model with mutant ITM2B/BRI2 and Tau (P301S) constructs.

To study the pathogenesis of FDD in the absence of potential artifacts due to transgenic overexpression of the mutant protein, a refined mouse model has been recently generated, which is based on a knock-in approach where the exon 6 of the murine ITM2B/BRI2 gene was substituted for by a mutant sequence carrying the human FDD mutation [18]. The analysis of FDDKI mouse model, carrying a mutant and a wild-type ITM2B/BRI2 allele, has shown that the Danish mutation causes impaired synaptic plasticity and deficits in hippocampal memory, in the absence of cerebral deposits and lesions [19]. A similar scenario applies to a Familial British Dementia (FBD) knock-in model, in which the dominant, mutant ITM2B/BRI2 allele responsible for FBD is associated to memory deficits and loss of BRI2 function, without the histopathological alterations typical to neurodegenerative disorders [20]. In agreement with the previously reported function of BRI2 in the stabilization of APP holoprotein [9, 12], FDDKI mice also show decreased BRI2 protein levels and increased levels of APP catabolites [19]; the latter evidence recapitulated the occurrence of increased APP metabolites in the brain of an FDD patient [13]. The functional link between ITM2B/BRI2 and APP genes is also strongly supported by the genetic suppression of memory and synaptic dysfunctions in FDDKI mice by APP haplo-deficiency [19] or inhibition of APP cleavage by β-secretase [20]. The functional association between ITM2B/BRI2 and APP genes strongly supports the participation of the encoded proteins to synaptic dysfunction. Accordingly, decreased levels of BRI2/APP complexes have been observed in the synaptic membranes of FDDKI mice [19].

In this paper, we profiled the expression pattern of synaptosomal proteins in the FDDKI mouse model, via differential expression analysis based on two-dimensional differential in-gel electrophoresis (2D-DIGE) in combination with tandem mass spectrometry. Our validated results showed decreased representation of the synaptosomal scaffold protein Psd95/Dlg4 and of the Dusp3 phosphatase in the FDDKI synaptosomes.

2. Materials and Methods

2.1. Mice, Preparation of Synaptosomal Extracts, and 2D-DIGE Analysis. Mice were handled according to the Ethical Guidelines for Treatment of Laboratory Animals of the Albert Einstein College of Medicine. The procedures were described and approved in animal protocol number 200404. FDDKI mice were on a C57BL/6J background. Crude synaptosomal fractions containing both membrane and soluble synaptosomal proteins were obtained from three biological replicates each of wild-type (C57BL/6J) or FDDKI mice, as described in [13]. Briefly, mouse brain homogenates in Hepsucrose buffer (20 mM Hepes/NaOH pH 7.4, 1 mM EDTA, 1 mM EGTA, and 0.25 M sucrose) supplemented with protease and phosphatase inhibitors (wt/vol = 10 mg tissue/100 mL buffer) were centrifuged at 800 ×g for 10 min, at 4°C. The supernatant (S1, total brain extract) was separated into supernatant (S2) and pellet (P2) by centrifugation at 9,200 ×g for 15 min, at 4°C. P2 fractions, representing the crude synaptosomal fractions, were resuspended in 7 M urea, 2 M thiourea, 4% CHAPS to extract the whole synaptosomal content, then precipitated in acetic acid/methanol (8:1, v:v) for 16 h, at –20°C, and finally recovered by centrifugation at 16,000 ×g for 30 min, at 4°C. The synaptosomal proteins were resuspended in 7 M urea, 2 M thiourea, 4% CHAPS, and 30 mM Tris-HCl; protein concentration was determined by using the Bradford method (Bio-Rad). Before labelling, the pH of the samples was adjusted to pH 8.5 with HCl solutions; each labelling reaction was performed in a 10 μL volume with 50 μg of the synaptosomal proteins, in the presence of 400 pmol of Cy2-, Cy3-, or Cy5-dyes (minimal labelling dyes, GE Healthcare). A dye-swapping strategy was used to label samples; accordingly, two samples from wild-type synaptosomal extracts were labelled with Cy3, while the third was labelled with Cy5; in a complementary manner, two samples from FDDKI extracts were labelled with Cy5, and the third was labelled with Cy3. Three mixtures of the 6 samples (50 μg each) were also labelled with Cy2 dye, as the internal standard required for the 2D-DIGE procedure. The labelling was performed for 30 min, at 0°C, in the dark, and was chased by the addition of 1 mM lysine. Three sample mixtures, made of appropriate Cy3- and Cy5-labeled pairs and a Cy2-labeled control, were supplemented with 1% (v/v) IPG buffer, pH 3–10 NL (GE Healthcare), 1.4% (v/v) De-Streak reagent (GE Healthcare), and 0.2% (w/v) DTT to a final volume of 450 μL in 7 M urea, 2 M thiourea, and 4% CHAPS. The mixtures (150 μg of total protein content) were used to passively hydrate the immobilized pH gradient IPG gel strips (24 cm, pH 3–10 NL) for 16 h, at 20°C. Isoelectric focusing (IEF) was carried out with an IPGPhor II apparatus (GE Healthcare) up to 75,000 Vh, at 20°C (current limit set to 50 μA per strip). The strips were equilibrated in 6 M urea, 2% SDS, 20% glycerol, and 0.375 M Tris-HCl (pH 8.8), for 15 min, in the dark, in the presence of 0.5% (w:v) DTT, and then in the presence of 4.5% (w/v) iodoacetamide in the same buffer, for additional 15 min. Equilibrated IPG strips were transferred onto 12% polyacrylamide gels, within low-fluorescence glass plates (ETTAN-DALT 6 system, GE Healthcare). The second-dimension SDS-PAGE was performed by using a DALT II electrophoresis unit (GE Healthcare) at 2 W/gel for 12 h. Gels were scanned with a Typhoon 9400 variable mode imager (GE Healthcare), using appropriate excitation/emission wavelengths for Cy2 (488/520 nm), Cy3 (532/580 nm), and Cy5 (633/670 nm). Images were acquired in the Image-Quant software (GE Healthcare) and analyzed by using the DeCyder 6.0 software (GE Healthcare). A DeCyder differential in-gel-analysis (DIA) module was used for spot detection and pairwise comparison of each sample (Cy3 and Cy5) to the Cy2, mixed standard present in each gel. The DeCyder biological variation analysis (BVA) module was then used to simultaneously match all of the protein-spot maps from the gels, and to calculate average abundance ratios and P values across the triplicate sets of samples (Student’s t-test).
For preparative protein separations, 500 μg of unlabeled protein samples from pooled, wild-type, and FDD\(_{KI}\) synaptosomal samples were used for passive hydration of 24 cm strips for the first gel dimension (pH 3–10 NL IPG strips, GE Healthcare). The first and second dimension runs were carried out as described above. After 2-DE, gels were fixed and stained with SyproRuby fluorescent stain (Invitrogen). After spot matching with the master gel from the analytical step in the BVA module of DeCyder software, a pick list was generated for spot picking by a robotic picker (Ettan spot picker, GE Healthcare).

2.2. Protein Identification and Bioinformatic Analysis. Spots from 2-DE were excised from gels, minced and washed with water. Proteins were in-gel reduced, S-alkylated, and digested with trypsin, as previously reported [21]. Protein digests were subjected to a desalting/concentration step on μZipTipC18 pipette tips (Millipore Corp., Bedford, MA, USA) and then analyzed by nanoLC-ESI-LIT-MS/MS using a LTQ XL mass spectrometer (ThermoFinnigan, USA) equipped with Proxeon nanospray source connected to an Easy-nanoLC (Proxeon, Denmark) [21, 22]. Peptide mixtures were separated on an Easy C\(_{18}\) column (10 × 0.075 mm, 3 μm) (Proxeon) using a gradient of acetonitrile containing 0.1% formic acid in aqueous 0.1% formic acid; acetonitrile ramped from 5% to 35% over 15 min and from 35% to 95% over 2 min, at a flow rate of 300 nL/min. Spectra were acquired in the range m/z 400–2000. Acquisition was controlled by a data-dependent product ion-scanning procedure over the mass isolation window and collision energy were set to repeat count 2 and exclusion duration 1 min. The mass isolation window and collision energy were set to m/z 3 and 35%, respectively. MASCOT software package version 2.2.06 (Matrix Science, UK) [23] was used to identify spots unambiguously from a nonredundant sequence database (all taxa UniProtKB 2010/01/09). NanoLC-ESI-LIT-MS/MS data were searched by using a mass tolerance value of 2 Da for precursor ion and 0.8 Da for MS/MS fragments, trypsin as the enzyme used for digestion, and a minimal score of 45. Protein identifications were searched against the nonredundant database (all UniProt knowledge database) to a mass tolerance value of 2 Da and a fragment mass tolerance of 0.8 Da. The mass spectra were matched to a nonredundant database (all taxa UniProtKB 2010/01/09). The Mascot search was performed with the following parameters: trypsin, no missed cleavages, fixed modifications of carbamidomethylation at cysteine and oxidation at methionine. The MS/MS fragmentation of the identified peptides was searched against the nonredundant database (all taxa UniProtKB 2010/01/09). The Mascot search was performed with the following parameters: trypsin, one missed cleavage, fixed modifications of carbamidomethylation and oxidation at methionine.

3. Results and Discussion

3.1. Differentially Expressed Proteins in Synaptosomes of FDD\(_{KI}\) Mice. In order to characterize the synaptosomal proteome of the available mouse model of FDD, we used the differential in-gel electrophoresis approach (2D-DIGE), which was applied to synaptosomal extracts from wild-type and FDD\(_{KI}\) mice. Indeed, three biological replicates of synaptosomal preparations from wild-type and FDD\(_{KI}\) mice were generated for protein extraction and fluorescence labelling with Cy-dyes. Analysis of the 2D-DIGE images, according to the DeCyder bioinformatic software, allowed us to detect about 2,000 matched protein spots within the three gels. We performed a quantitative and statistical analysis under parameters defined as relative expression ratio in FDD\(_{KI}\) versus WT mice of >1.25 for protein spots upregulated and of <−1.25 for protein spots downregulated, with a P value <0.05. We found that twelve spots appeared to be deregulated (circled in Figure 1(a)); in particular, four protein spots were upregulated, whereas eight protein spots were downregulated, in FDD\(_{KI}\) versus WT mice.

In order to identify the differentially expressed proteins, the spots of interest were matched to the corresponding ones from a preparative gel stained with fluorescent stain SyproRuby (yellow circles in Figure 1(b)), which were then individually excised, digested with trypsin, and finally identified by nanoLC-ESI-LIT-MS/MS analysis, as detailed in Methods. Table 1 summarizes the relative spot expression ratios in FDD\(_{KI}\) versus WT mice as well as the mass spectrometry data for the corresponding identified proteins.

3.2. Functional Classification of the Identified Proteins. In order to find relevant proteins among the multiple identifications obtained by proteomic analysis, we subjected the list of the 13 proteins from Table 1 to bioinformatic analysis in the String database, which integrates interaction data from several bioinformatic sources and provides information about physical and functional, known and predicted interactions of genes and their products [24] (Figure 2). String analysis showed that Dlg4 protein is directly linked to 4 additional proteins, namely Ppp3ca, Hspa8, Atp6v1a, and Gnb1. The evidences responsible for those functional associations are mainly experimental (purple line), and reflect protein-protein interactions [27–29]. Indeed, Dlg4, also known as postsynaptic density protein 95 (Psd95), contributes to the organization of multiprotein complexes at the postsynaptic
Indeed, the two proteins are the beta 1 and beta 2 components of heterotrimeric G protein complexes, respectively. These proteins share a high protein sequence identity (>90%) in mouse, in fact they were co-identified in spot 2632 (Table 1). Additional associations involving the differentially expressed proteins in FDDK1 mice involved the kinesin family member 5a (Kif5a), a microtubule-dependent motor protein involved in the axonal transport of neurofilament proteins and organelles, and the kinesin family member 5c (Kif5c), involved in organelle transport. Interestingly, Kif5a and an additional protein identified in this study in multiple deregulated spots (spots 890, 891, 918, and 957), namely, dihydropyrimidinase-related protein 2 (Dpysl2), were found as differentially expressed during a proteomic profiling of an AD-transgenic model with preplaque (2 months) and plaque (24 months) phenotypes [32].

The DAVID database, which analyzes gene or protein lists deriving from high-throughput experiments and systematically extracts biological meaning from them [25, 26], was also used to highlight the functional annotation clustering inside the potential protein network identified by our proteomic analysis. The main descriptor found for molecular functions was the “nucleoside-triphosphatase activity” (GOTERM_MF_ALL; \( P = 6.2E-5 \)), which included 6 out of the 13 identified proteins (Atp6v1a, Kif5a, Kif5c, Gnb1, Gnb2, and Hspa8; Figure 2, proteins inside the blue box). An additional cluster was associated to the “MAPK signaling pathway” and included heat shock cognate 71 kDa protein (Hspa8) and two phosphatases, namely, protein phosphatase 3, catalytic subunit, alpha isoform (Ppp3ca), and dual specificity phosphatase 3 (Dusp3) (KEGG_Pathway \( P = 6.2E-2 \)) (Figure 2, green box). These phosphatases, although at a lower statistical value, were also annotated with the ATPase, H+ transporting, lysosomal V1 subunit A (Atp6v1a) in the biological process “phosphate metabolic process” (GOTERM_BP_FAT \( P = 2.7E-1 \)).

### 3.3. Validation of 2D-DIGE Results by Western Blot Analysis of Proteins Differentially Expressed in FDDK1 Mice

Differentially expressed proteins from 2D-DIGE analysis were mainly classified according to their functional annotation into “nucleoside-triphosphatase activity” or their involvement in “MAPK signaling pathway” (Figure 2). We then selected some representative members of the two groups, namely Dlg4/Psd95, which is a prominent scaffold protein in synaptosomal architecture/function, and is also associated with nucleoside-triphosphatase activity, was also assayed.

Western blotting analysis definitively demonstrated that Dlg4/Psd95 was slightly downregulated in synaptosomal extracts from FDDK1 mice, in strong agreement with 2D-DIGE data (expression ratio \(-1.27, P = 0.025\); see Table 1) (Figure 3(a)). In contrast, no positive confirms were observed for the selected proteins associated with “nucleoside-triphosphatase activity,” namely, Kif5a and Dpysl2.

Figure 2: Bioinformatic analysis of the differentially expressed proteins. The list of the MS-identified protein spots from 2D-DIGE was subjected to String (v. 8.3) analysis to reveal functional interactions between the deregulated proteins. Interacting proteins are connected by lines of different colors, according to the color code shown at the bottom of the figure. The reported values close to the lines indicate the confidence scores, as revealed by the functional interaction analysis. The original graphic output was modified to fit the proteins in the blue and green boxes, according to their classification under the gene ontology descriptors "Molecular function: nucleoside triphosphatase activity" and "KEGG pathway: MAPK signaling pathway," as revealed by the DAVID (v. 6.7) annotation system.

(Alternative results were obtained for phosphatase members of the “MAPK signaling cascade.” In fact, a good correlation between 2D-DIGE and western blotting analysis was observed for Dusp3, while contradictory results were obtained for Ppp3ca (Figure 3(a)). Negative correlation data between the two analytical methods were easily explained on the basis of the differential expression of specific protein isoforms bearing posttranslational modifications. Thus, post-transcriptional events should regulate abundance of specific protein isoforms in FDDK1 synaptosomes. In this context, protein phosphorylation and dephosphorylation is a relevant process in synaptic activity. For example, after exocytosis for neurotransmitter release, the synaptic vesicles are retrieved by endocytosis to accomplish additional cycles of synaptic transmission. In the paradigm, several proteins involved in synaptic function are dephosphorylated, during synaptic vesicle endocytosis, and rephosphorylated after recycling to maintain the maintenance of synaptic transmission [33]. Ppp3ca phosphatase is associated to these activities. Although global levels of this protein seemed unchanged in the FDDK1 synaptosomes by western blotting, 2D-DIGE analysis suggested downregulation of a specific Ppp3ca isoform. On the contrary, Dusp3 downregulation in the FDDK1 synaptosomes was definitively validated in the synaptosomal preparations, as a nongeneralized phenomenon in mouse brain. In fact, western blot analysis of Dusp3 in crude brain lysates showed slightly increased protein levels in the unfractionated FDDK1 samples (Figure 3(b)). Dual-specificity phosphatases constitute a heterogeneous group of enzymes with the ability to recognize either phospho-Tyr or phospho-Ser/Thr substrates and act in the regulation of JNK- and Erk-mediated pathways [34]. At the present, no evidences have been published that support a Dusp3 function in the nerve system and in synaptic functionality, although one can speculate the involvement of this phosphatase also in the central nerve system, given the relevant functions of the ERK kinases in the signal transduction mechanisms in the brain [35].

4. Conclusions

The results of this work outline a differential expression of selected proteins in the synaptosomes of FDDK1 mice. Eight

protein spots were downregulated, while four protein spots were upregulated in the FDD\textsubscript{K1} synaptosomal extracts. Western blot analysis on selected proteins, guided by the results of bioinformatic classification of the deregulated proteins, showed that two signalling proteins, namely, Dlg4/Psd95 and Dusp3, were actually downregulated in the available animal model of FDD. The first one (Dlg4/Psd95) is a well-known scaffold protein in synaptic function, and its downrepresentation in the synaptosomes of FDD\textsubscript{K1} mice may impair synaptic transmission and activity. The second protein (Dusp3), a known regulator of Jnk- and Erk-mediated pathways, is not as well studied in the central nervous system. However, the evidence provided may stimulate further studies at the phosphoproteomic and functional levels, to assess its synaptosomal targets, and to define the role of its downregulation in brain physiology and in the mechanisms associated with FDD and additional neurodegenerative disorders, including FBD and AD.
Figure 3: Validation of the 2D-DIGE results by western blot analysis. (a) Triplet synaptosomal preparations from wild-type and FDDKI mouse synaptosomes were separated on SDS-PAGE gels and transferred to membranes for western blot analysis with antibodies against the indicated proteins. Actual downregulation in the synaptosomal samples of FDDKI mice can be observed for Dlg4/Psd95 and Dusp3 proteins. Actin antibody was used to show equal loading of the protein extracts. (b) Total brain homogenates from wild-type and FDDKI mice were analyzed by western blot with antibodies against Dusp3. Tubulin antibody was used to show equal loading of the protein extracts.

Abbreviations

2-DE: Two-dimensional electrophoresis
2D-DIGE: Two-dimensional differential in-gel electrophoresis
AD: Alzheimer’s disease
FBD: Familial British Dementia
FDD: Familial Danish Dementia
MS: Mass spectrometry
nanoLC-ESI-LIT-MS/MS: Nanoliquid chromatography coupled to electrospray-linear ion trap tandem mass spectrometry
SDS-PAGE: Sodium dodecyl sulphate-polyacrilamide gel electrophoresis.

Acknowledgments

N. Zambrano has been supported by funds from Ministero dell’Università e della Ricerca Scientifica (PS 126-1nd) and from Regione Campania (L.R. n. 5, Annualità 2007), and L. D’Adamio has been supported by Grants from Alzheimer’s Association (IIRG-09-129984 and ZEN-11-201425), the Edward N. & Della L. Thome Memorial Foundation grant, and the National Institutes of Health (NIH; R01AG033007). Authors thank T. Russo and the Centro Regionale di Competenza Genomics for Applied Research, Regione Campania (GEAR) for granting access to the 2D-DIGE facility. M. Vitale and G. Renzone gave an equal contribution to this work.
