Spin Hall effect of gravitational waves

Naoki Yamamoto

Department of Physics, Keio University, Yokohama 223-8522, Japan

Gravitons possess a Berry curvature due to their helicity. We derive the semiclassical equations of motion for gravitons taking into account the Berry curvature. We show that this quantum correction leads to the splitting of the trajectories of right- and left-handed gravitational waves in curved space. This is the spin Hall effect (SHE) of gravitational waves. We find that the SHE of gravitational waves is twice as large as that of light. Possible future observations of the SHE of gravitational waves can potentially test the quantum nature of gravitons beyond the classical general relativity.

I. INTRODUCTION

One of the important predictions in Einstein’s theory of general relativity is the gravitational lensing, the deflection of light rays in a gravitational field around a massive object. However, the classical gravitational lensing of light in curved space receives a modification, expressible in terms of Berry curvature, due to the helicity of photons [1]. In particular, such a quantum correction leads to the splitting of the trajectories of right- and left-handed circularly polarized light. In the context of optics, a closely related effect of light is known in an optically inhomogeneous medium and is called the optical Magnus effect or spin Hall effect of light [7–10].

In this paper, we show that gravitational waves exhibit the quantum spin Hall effect similarly to light, and that the effect is twice as large as that of light. Our result shows that, although the trajectories of both light and gravitational wave in the curved space are null geodesic and are degenerate classically in the geometric-optics limit, this degeneracy is resolved quantum mechanically by their helical nature.

For this purpose, we first show that gravitons possess a Berry curvature due to their helicity, and derive the semiclassical equations of motion for gravitons taking into account the Berry curvature. We then show that the quantum correction to the gravitational lensing of gravitational waves in curved space is expressed by the Berry curvature. Our work demonstrates the importance of the notion of Berry curvature even in the gravitational physics, which has been mostly investigated in the context of condensed matter physics [11] and has just recently been applied in high-energy physics [12, 14] and astrophysics [15].

---

1 The deflection of massless spinning particles in a gravitational field was previously studied in Refs. [2–4] and that of circularly polarized light around rotating massive objects in Refs. [5, 6] in different contexts. Except for Ref. [1], however, the spin Hall effect of light in curved space in terms of Berry curvature has not been discussed.
II. SPIN HALL EFFECT OF LIGHT IN GRAVITY

We first illustrate the spin Hall effect (SHE) of light in a gravitational field. To keep the relativistic and quantum mechanical nature apparent, we will explicitly write $\hbar$ and $c$ in this section.

Let us first recall the classical gravitational lensing of light in a gravitational potential $\phi(x)$. Consider the case in a weak gravitational field, where the metric is given by

$$ ds^2 = \left(1 + \frac{2\phi}{c^2}\right) c^2 dt^2 - \left(1 - \frac{2\phi}{c^2}\right) (dx)^2. \quad (1) $$

Here, we assume $\phi$ is static and satisfies $|\phi|/c^2 \ll 1$. Because the light propagates along a null geodesic, $ds^2 = 0$, the coordinate velocity of light is given by

$$ c' \equiv \frac{|dx|}{dt} = c \sqrt{\frac{1 + \frac{2\phi}{c^2}}{1 - \frac{2\phi}{c^2}}} \approx c \left(1 + \frac{2\phi}{c^2}\right). \quad (2) $$

It has been known that the null geodesic equation in the static and weak gravitational potential is equivalent to the geometric-optical equation of light rays in a medium with refractive index $n(x)$ that varies depending on $\phi(x)$ [16]. Equation (2) shows that the refractive index is given by

$$ n = \sqrt{\frac{1 - \frac{2\phi}{c^2}}{1 + \frac{2\phi}{c^2}}} \approx 1 - \frac{2\phi}{c^2}. \quad (3) $$

For $\phi < 0$, $c' < c$ and $n > 1$. This feature, despite being applicable to generic solutions of Maxwell’s equations in curved space (see, e.g., Ref. [17] and references therein), allows us, in particular, to describe the effects of weak gravity using purely the language of the geometric optics. In the following, we will consider the action of photons in the geometric-optics limit where the wavelength of light is much smaller than the radius of curvature of the background gravity.

We now note that the equations of motion for light in curved space are also affected by the helicity. In the semiclassical regime, the helical nature of photons can be expressed by the Berry connection or Berry curvature [7–9, 18]. The action for right- and left-handed circularly polarized light in the weak gravity is given by

$$ I^\gamma = \int dt \ (p \cdot \dot{x} - a^\gamma_p \cdot \dot{p} - \epsilon_p). \quad (4) $$

Here, $a^\gamma_p$ is the Berry connection of photons, which is related to the Berry curvature $\Omega^\gamma_p$ via

$$ \Omega^\gamma_p \equiv \nabla_p \times a^\gamma_p = \frac{\lambda \dot{p}}{p^2}, \quad (5) $$

A similar result was obtained in Ref. [1] in a different way.
where \( \hat{p} \equiv p/|p|, p \equiv |p| \), and \( \lambda \) is the helicity of photons (\( \lambda = \pm \hbar \) for right- and left-handed photons, respectively). As we explained above, the effect of the static gravitational potential is accounted for by the refractive index \( \epsilon_p \), which modifies the energy dispersion of photons as

\[
\epsilon_p = pc' = \frac{pc}{n},
\]

where \( c' \) and \( n \) are given by Eqs. (2) and (3).

The semiclassical equations of motion for the wave packet of light are obtained from the action (4) as

\[
\dot{x} = \frac{c}{n} \hat{p} + \hat{p} \times \Omega_p,
\]

\[
\dot{p} = -\frac{2p}{c} \nabla \phi.
\]

In the context of the geometric optics, the second term in Eq. (7) is called the optical Magnus effect [7, 8]. On the other hand, Eq. (8) represents the (classical) gravitational lensing effect in the gravitational potential \( \phi \). Inserting Eq. (8) into Eq. (7), we have

\[
\dot{x} = \frac{c}{n} \hat{p} - \frac{2\lambda}{c} \nabla \phi \times \hat{p}.
\]

The second term represents the quantum spin Hall effect of light induced by the background curved geometry. The trajectory of light is shifted in the direction perpendicular to both \( \nabla \phi \) and the classical trajectory \( \hat{p} \), and in particular, the trajectories of right- and left-handed circularly polarized light are separated. This effect originates from the interplay between general relativity and the helical nature of right- or left-handed photons.

As an example, consider the Newtonian potential at a distance \( r \) from a point mass \( M \):

\[
\phi(r) = -\frac{GM}{r},
\]

where \( G \) is the universal gravitational constant. In this case, Eq. (9) reduces to

\[
\dot{x} = \frac{c}{n} \hat{p} - \frac{2\lambda GM}{c} \frac{\hat{r}}{r^2} \times \hat{p}.
\]

Equation (11) shows that the SHE becomes larger as \( M \) increases and as \( p \) decreases (for fixed \( r \)). Thus, the SHE becomes particularly relevant for electromagnetic waves with long wavelength around massive astrophysical objects.

It is straightforward to get the generic kinetic theory for photons in the weak gravitational field. By inserting Eqs. (8) and (9) into the kinetic equation,

\[
\frac{\partial f_\lambda}{\partial t} + \dot{x} \cdot \frac{\partial f_\lambda}{\partial x} + \dot{p} \cdot \frac{\partial f_\lambda}{\partial p} = C[f_\lambda],
\]

\( ^3 \) For a system in a rotation \( \omega \), we have the additional Coriolis force \( 2|p|\dot{x} \times \omega \) in Eq. (8) in a rotation frame, which, combined with the Berry curvature correction in Eq. (7), leads to the “photonic chiral vortical effect” (see also Refs. 19, 20 for other derivations).

where \( f_\lambda = f_\lambda(t, x, p) \) is the distribution function of photons with helicity \( \lambda \) and \( C[f_\lambda] \) is the collision term, we get
\[
\frac{\partial f_\lambda}{\partial t} + \left( \frac{c}{n} \hat{p} - \frac{2\lambda}{c} \nabla \phi \times \hat{p} \right) \cdot \frac{\partial f_\lambda}{\partial x} - \frac{2p}{c} \nabla \phi \cdot \frac{\partial f_\lambda}{\partial p} = C[f_\lambda].
\] (13)

This equation describes the time evolution of right- and left-handed photons for any given (weak and static) gravitational field \( \phi \).

III. SPIN HALL EFFECT OF GRAVITATIONAL WAVES

In this section, we consider the SHE of gravitational waves in the semiclassical regime. At the classical level, the gravitational wave travels along a null geodesic, and hence, the propagation of the gravitational wave in curved space is described by the same geometric-optical equation as the case of light [21]. We will show that gravitons possess a Berry curvature in the semiclassical regime, leading to the SHE of gravitons in curved space, similarly to that of photons above.

A. Generalized Weyl equation with any helicity

Let us briefly review the generalized Weyl equation for massless fields with any spin [23, 24], and then we apply it to spin-2 gravitons. In the following, we use the natural units \( \hbar = c = 1 \) for simplicity, unless stated otherwise.

We first recall the representation of the Poincaré algebra for massless fields. The Poincaré symmetry consists of the space-time translations generated by the energy-momentum vector \( p^\mu \) and the Lorentz transformations generated by \( M^{\mu\nu} \). In 3+1 space-time dimensions, there are two Casimir operators that commute with \( p^\mu \) and \( M^{\mu\nu} \): \( p^2 = p^\mu p_\mu \) and \( W^2 = W^\mu W_\mu \), where \( W^\mu \) is the Pauli-Lubanski vector defined by
\[
W^\mu = -\frac{1}{2} \epsilon^{\mu\nu\alpha\beta} p_\nu M_{\alpha\beta}.
\] (14)

Because the contribution of the orbital angular momentum vanishes due to the antisymmetry with \( p_\nu \), Eq. (14) can also be rewritten as
\[
W^\mu = -\frac{1}{2} \epsilon^{\mu\nu\alpha\beta} p_\nu S_{\alpha\beta} = -p_\nu \tilde{S}^{\mu\nu}, \quad \tilde{S}^{\mu\nu} \equiv \frac{1}{2} \epsilon^{\mu\nu\alpha\beta} S_{\alpha\beta},
\] (15)

where \( S^{\mu\nu} \) is the spin tensor, whose components are \( S^{ij} = \epsilon^{ijk} S_k \) and \( S^{0i} = i S^i \) with \( S^i \) being the spin vector.

Let us now introduce the \((2|\lambda| + 1)\)-component massless field \( \psi \) with helicity \( \lambda \), which satisfies the equation
\[
W^\mu \psi = \lambda p^\mu \psi,
\] (16)
according to Wigner’s result \[22\]. Using Eq. (15), this equation can be written as

\[
(\tilde{S}^{\mu\nu} p_\nu + \lambda p^\mu)\psi = 0.
\] (17)

The temporal ($\mu = 0$) and spatial ($\mu = i$) components of this equation are given by

\[
(S \cdot p - \lambda p^0)\psi = 0,
\] (18)

\[
(Sp^0 + iS \times p - \lambda p)\psi = 0,
\] (19)

respectively. Equation (18) is the generalized Weyl equation for massless field with helicity $\lambda$, and Eq. (19) is the subsidiary condition \[23, 24\]. The generalized Weyl Hamiltonian corresponding to the wave equation (18) is

\[
H = \frac{1}{\lambda} S \cdot p.
\] (20)

Note that three components of Eq. (19) are not independent. To see this, we first eliminate $p^0$ in Eq. (19) using Eq. (18) to get

\[
\left[\frac{1}{\lambda} S(S \cdot p) + i S \times p - \lambda p\right] \psi = 0.
\] (21)

It is then easy to check that the inner product of the left-hand side of Eq. (21) with $S$ vanishes, meaning that only one of three components in Eq. (21) is independent. Without loss of generality, we take the $z$-component of Eq. (21),

\[
\left[\frac{1}{\lambda} S_z(S \cdot p) + i (S_xp_y - S_y p_x) - \lambda p_z\right] \psi = 0,
\] (22)

as the subsidiary condition to Eq. (18).

In particular, for gravitons with $\lambda = 2$, a matrix representation of $S$ is

\[
S_x = \begin{pmatrix}
0 & 1 & 0 & 0 & 0 \\
1 & 0 & \sqrt{\frac{3}{2}} & 0 & 0 \\
0 & \sqrt{\frac{3}{2}} & 0 & \sqrt{\frac{3}{2}} & 0 \\
0 & 0 & \sqrt{\frac{3}{2}} & 0 & 1 \\
0 & 0 & 0 & 1 & 0
\end{pmatrix},
S_y = i \begin{pmatrix}
-1 & 0 & 0 & 0 & 0 \\
0 & -\sqrt{\frac{3}{2}} & 0 & 0 \\
0 & \sqrt{\frac{3}{2}} & 0 & -\sqrt{\frac{3}{2}} & 0 \\
0 & 0 & \sqrt{\frac{3}{2}} & 0 & 1 \\
0 & 0 & 0 & 1 & 0
\end{pmatrix},
\] (23)

and $S_z = \text{diag}(2, 1, 0, -1, -2)$.

\section*{B. Path integral formulation of gravitons in flat space}

Once the wave equation (18) for gravitons is obtained, the semiclassical equations of motion for gravitons taking into account the Berry curvature can be derived in a way analogous
to Ref. [13] for chiral fermions. The important difference in our case is, however, the additional constraint (22), which selects out the physical degrees of freedom of gravitons with helicity $\pm 2$, similarly to the situation of photons with helicity $\pm 1$ [18].

Let us consider the path integral quantization for the Hamiltonian (20) for $\lambda = 2$:

$$Z = \int \mathcal{D}x \mathcal{D}p \mathcal{P} e^{i\mathcal{I}}, \quad \mathcal{I} = \int dt (p \cdot \dot{x} - H),$$

(24)

where $\mathcal{P}$ denotes the path-ordered product of the matrices $\exp(-iH\Delta t)$ over the path in the phase space. The eigenvalues of $H$ are given by $\pm|p|, \pm\frac{1}{2}|p|$, and 0, and $H$ can be diagonalized using a unitary matrix $V_p$ as

$$V_p^\dagger HV_p = |p|\Gamma, \quad \Gamma \equiv \frac{1}{2}S_z.$$ (25)

The eigenstates of the eigenvalues $-|p|$ and $-\frac{1}{2}|p|$ have the negative energies and are not physical. Also, one can check that the eigenstates of the eigenvalues 0 and $\frac{1}{2}|p|$ are forbidden by the subsidiary condition (22). Therefore, we have only one physical eigenstate with the eigenvalue $|p|$, which corresponds to helicity $\lambda = 2$.

Following the procedure in Refs. [13, 18], we diagonalize the matrix in the exponential factor of the path integral (24) at each point of the trajectory as

$$\cdots \exp\left(-\frac{i}{2}S \cdot p_2 \Delta t\right) \exp\left(-\frac{i}{2}S \cdot p_1 \Delta t\right) \cdots = \cdots V_{p_2} \exp(-i|p_2|\Gamma \Delta t)V_{p_2}^\dagger V_{p_1} \exp(-i|p_1|\Gamma \Delta t)V_{p_1}^\dagger \cdots$$

$$= \cdots V_{p_2} \exp(-i|p_2|\Gamma \Delta t) \exp(-i\hat{\alpha}_p^G \cdot \dot{p} \Delta t) \times \exp(-i|p_1|\Gamma \Delta t)V_{p_1}^\dagger \cdots,$$ (26)

where $\hat{\alpha}_p^G \equiv iV_{p_2}^\dagger \nabla_p V_{p_1}$. In deriving the last equation above, we used

$$V_{p_2}^\dagger V_{p_1} \approx \exp(-i\hat{\alpha}_p^G \cdot \Delta p) = \exp(-i\hat{\alpha}_p^G \cdot \dot{p} \Delta t)$$ (27)

for sufficiently small $\Delta p \equiv p_2 - p_1$.

Taking the semiclassical limit where off-diagonal components of $\hat{\alpha}_p^G$ are ignored, we obtain the semiclassical action for gravitons in the flat space:

$$I^G = \int dt (p \cdot \dot{x} - \alpha_p^G \cdot \dot{p} - \epsilon_p),$$

(28)

where $\epsilon_p = |p|$ is the energy dispersion and $\alpha_p^G \equiv [\hat{\alpha}_p]_{11}$ is the Berry connection in momentum space that originates from the helicity of gravitons. From the definition of $\alpha_p^G$ above, one finds the Berry curvature of gravitons as

$$\Omega_p^G \equiv \nabla_p \times \alpha_p^G = \lambda \frac{\dot{p}}{|p|^2},$$ (29)

where $\lambda$ is the helicity of gravitons. This corresponds to the fictitious magnetic field of the magnetic monopole with charge,

$$k = \frac{1}{4\pi} \int \Omega_p^G \cdot dS = \lambda.$$ (30)
Note that Eq. (30) is a general relation applicable not only to gravitons, but also to photons and chiral fermions: $k = \pm 2$ for gravitons with $\lambda = \pm 2$ (as shown here), $k = \pm 1$ for photons with $\lambda = \pm 1$ \cite{18}, and $k = \pm \frac{1}{2}$ for chiral fermions with $\lambda = \pm \frac{1}{2}$ \cite{12–14}.

C. Semiclassical equations of motion for gravitons in curved space

In the weak and static gravitational potential $\phi(x)$, the energy dispersion of gravitons is modified as Eq. (6) in the same way as photons, where $n$ is the “refractive index” of space in Eq. (3). In this case, the action of the graviton is given by Eq. (28) with $\epsilon_\mu$ being replaced by Eq. (6). Then, the semiclassical equations of motion for gravitons become

$$\dot{x} = \frac{c}{n} \hat{p} + \hat{p} \times \Omega^G_p,$$

$$\dot{p} = -\frac{2p}{c} \nabla \phi. \quad (31)$$

The second term on the right-hand side of Eq. (31) is the “Lorentz force” in momentum space, which may be regarded as the gravitational Magnus effect. To the best of our knowledge, this effect has not been studied so far.

From the two equations above, we obtain Eq. (9) with helicity $\lambda = \pm 2$. The second term of this equation is the SHE of the gravitational wave, which is twice as large as that of light because of the difference of helicity. This means that, although the trajectory of the gravitational wave in curved space is classically the same as that of light in the geometric-optics limit, this degeneracy of trajectories is lifted by the quantum effects.

Similarly to the case of photons, the kinetic equation for gravitons in the weak gravity is given by Eq. (13) with $f_\lambda = f_\lambda(t, x, p)$ being replaced by the distribution function of gravitons.

IV. DISCUSSIONS

In this paper, we derived the quantum correction to the gravitational lensing of gravitational waves in curved space. In particular, this correction causes the splitting of the trajectories of right- and left-handed circularly polarized gravitational waves.

To quantify the SHE in gravity, consider an electromagnetic wave or a gravitational wave passing near a Schwarzschild black hole as an example.\(^4\) From Eq. (11), the relative magnitude of the local shift due to the SHE, compared with the classical trajectory, is written as

$$A = \frac{n|\lambda|}{2\pi\hbar} \left( \frac{R_s}{r} \right)^2 \left( \frac{\ell}{R_s} \right), \quad (33)$$

\(^4\) For a study of the classical gravitational lensing by a Schwarzschild black hole, see Ref. 25.
where $R_s = 2GM/c^2$ is the Schwarzschild radius, $r$ is the distance from the black hole, and $\ell$ is the wavelength. This relation shows that the SHE becomes more relevant as $\ell$ becomes larger, as long as the semiclassical approximation is valid. For example, for a black hole with solar mass $M = M_\odot$, the relative magnitude is $A \sim 10^{-3}$ for $r \sim 5R_s$ and $\ell \sim 300$ m.

It does not seem feasible to observe the SHE both for electromagnetic and gravitational waves by the current detectors. However, possible future observations of the SHE of gravitational waves, in particular, could test the quantum nature of gravitons beyond the classical general relativity.
