CONSTRUCTING ORDERED ORTHOGONAL ARRAYS VIA SUDOKU

JOHN LORCH

Abstract. For prime powers \( q \) we use “strongly orthogonal” linear sudoku solutions of order \( q^2 \) to construct ordered orthogonal arrays of type OOA(4, s, 2, q), and for each \( q \) we present a range of values of \( s \) for which these constructions are valid.

1. Introduction

1.1. Purpose. It has long been known that families of mutually orthogonal latin squares have important connections and applications to finite geometry, statistical design, and graph theory, many of which are illustrated in [4] and [13]. This is exemplified by the following Theorem (e.g., see [4] or [13]).

**Theorem 1.1.** Let \( n, s \in \mathbb{Z}^+ \) with \( 3 \leq s \leq n + 1 \). The following are equivalent:

(a) There exists a collection of \( s - 2 \) mutually orthogonal latin squares of order \( n \).
(b) There exists a Bruck net of order \( n \) and degree \( s \).
(c) There exists a transversal design of type TD(s, n).
(d) There exists an orthogonal array of type OA(s, n).
(e) There exists an edge partition of the complete \( s \)-partite graph \( K_{n,...,n} \) into complete subgraphs of order \( s \).

A sudoku solution is a special kind of latin square. Given that families of mutually orthogonal sudoku solutions have become of interest in their own right (e.g., see [3], [6], [7], [9], [10], [12]), it is reasonable to seek combinatorial ‘soul mates’ for orthogonal sudoku solutions, along the lines of those given for latin squares in Theorem 1.1. Ordered orthogonal arrays of type OOA(4, s, 2, q) seem to make good candidates: In this paper we show that when \( q \) is a prime power, special families of mutually orthogonal sudoku solutions of order \( q^2 \) can be used to construct ordered orthogonal arrays of this type.

1.2. Background. For a positive integer \( n \), a **sudoku solution** of order \( n^2 \) is an \( n^2 \times n^2 \) Latin square with the additional requirement that every symbol must appear in each canonical \( n \times n \) subsquare. These occur in case \( n = 3 \) when one is lucky enough to solve the newspaper sudoku puzzle (Figure 1). Locations in a sudoku solution of order \( n^2 \) can be populated by any set of \( n^2 \) distinct symbols; we use symbols \( \{0, 1, \ldots, n^2 - 1\} \).

\[ \text{Date: September 2013.} \]
\[ \text{1991 Mathematics Subject Classification. 05B15.} \]
Two latin squares of like order are said to be orthogonal if, upon superimposition, each ordered pair of symbols appears exactly once (Figure 2). Families of pairwise orthogonal latin squares have long been an object of study, in part due to connections illustrated in Theorem 1.1. One of the most famous open problems concerning orthogonal latin squares is determining the maximum size \( N(n) \) of a family of pairwise mutually orthogonal latin squares of order \( n \). It is well known that \( N(n) \leq n - 1 \), and, due to field theoretic considerations, that \( N(n) = n - 1 \) when \( n \) is a prime power (e.g., [13] and [11]). Orthogonality questions for latin squares specialize to sudoku. For instance, it is known that the maximum size of a family of pairwise mutually orthogonal sudoku solutions of order \( n^2 \) is \( n(n-1) \), and that this bound is achieved when \( n \) is a prime power (e.g., [3], [10], [12]). Linear sudoku solutions, which are useful for creating mutually orthogonal families of sudoku solutions, play a key role in the present work and will be defined carefully in Section 4.

Part (d) of Theorem 1.1 indicates that families of mutually orthogonal latin squares are characterized by orthogonal arrays. In the spirit of this theorem, we explore connections between mutually orthogonal sudoku solutions and ordered orthogonal arrays. An ordered orthogonal array of type \( \text{OOA}_\lambda(t, s, \ell, v) \) consists of an \( s\ell \times \lambda v^t \) array whose entries are drawn from an alphabet of size \( v \). This array must satisfy a condition that requires explanation: Rows of the array are partitioned into \( s \) bands, each of width \( \ell \), and can be labeled lexicographically from top to bottom by ordered pairs \( \{(i, j) \mid 1 \leq i \leq s, 1 \leq j \leq \ell\} \). A set \( T \) of \( t \) rows within this array is said to be top-justified if whenever the \( (i, j) \)-th row lies in \( T \) we have that the \( (i, k) \)-th row also lies in \( T \) for \( 1 \leq k \leq j \). Regarding a set \( T \) of top justified rows as a sub-array of the original array, we require that each \( t \)-tuple column of \( T \) occurs exactly \( \lambda \) times in this subarray. (See Figure 3 for an example.) Ordered orthogonal arrays are generalizations of orthogonal arrays: one obtains an ‘ordinary’ orthogonal array
by putting $\ell = \lambda = 1$ and $t = 2$. We will focus on the case $\ell = 2$, $\lambda = 1$, and $t = 4$. We follow the custom of dropping the $\lambda$ subscript from OOA when $\lambda = 1$.

$\begin{array}{cccccccccccccccc}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\
0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 \\
0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\
0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 \\
0 & 0 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 1 & 1 \\
\end{array}$

**Figure 3.** An ordered orthogonal array of type OOA(4,3,2,2). A set of top-justified rows is shown in bold.

Ordered orthogonal arrays were first defined for arbitrary parameters in [8], where for certain parameters they are used to characterize $(t, m, s)$-nets, which in turn have significant applications in quasi-Monte Carlo methods. Constructions of ordered orthogonal arrays and associated $(t, m, s)$-nets may be found in [8], [1], and [2].

Many existence and construction questions concerning ordered orthogonal arrays continue to be open. In this paper we prove that when $q$ is a prime power, ordered orthogonal arrays of type OOA(4, $s$, 2, $q$) exist whenever $s \leq \frac{q+7}{4}$, and whenever $q \leq \frac{q+4}{2}$ in the special case that $q$ is a power of two (Theorem 5.4 and Corollary 5.5). These are not the best possible existence results for small values of $q$, such as $q = 3, 4, 5$, which necessarily result in $s < 6$: In Theorem 5.2 and Corollary 5.3 we determine the existence of arrays of type OOA(4, 3, 2, $q$) and OOA(4, 4, 2, $q$). Results in this paper rely strongly on flags of subspaces in a four dimensional vector space over a finite field.

The structure of the paper is as follows: In Section 2 we identify mutually orthogonal families of sudoku solutions with arrays that have the potential to be ordered orthogonal arrays (Theorem 2.1). In Section 3 we tease out necessary and sufficient conditions that must be satisfied by a collection of orthogonal sudoku solutions in order to give rise to an ordered orthogonal array (Proposition 3.2). The conditions of Section 3 are translated to a linear setting in Section 4, and sudoku flags are introduced. Using the machinery of sudoku flags, construction of ordered orthogonal arrays occurs in Section 5.

2. **Sudoku arrays**

In this section we produce an exact analog of Theorem 1.1, part (d), for sudoku. We will also observe that every ordered orthogonal array of type OOA(4, $s$, 2, $n$) determines a special family of $s - 2$ mutually orthogonal sudoku solutions of order $n^2$.

\[^1\]Several papers, including Lawrence’s original paper [8], refer to ordered orthogonal arrays as “generalized orthogonal arrays.” We follow the terminology of [4]. Also, $(t, m, s)$ nets are “low discrepancy” multisets in $[0, 1)^t$ and should not be confused with Bruck nets. The ordered orthogonal arrays considered in this paper do not characterize $(t, m, s)$ nets.
We briefly introduce terminology that will be used frequently as we proceed. If \( b_n b_1 \) is the base-\( n \) representation of \( x \in \{0, 1, \ldots, n^2 - 1\} \), meaning \( x = b_n \cdot n + b_1 \cdot 1 \) and \( b_n, b_1 \in \{0, 1, \ldots, n - 1\} \), we call \( b_n \) the radix digit of \( x \) and \( b_1 \) the units digit. Locations within an order-\( n^2 \) sudoku solution can be identified with four-tuples \( (x_1, x_2, x_3, x_4) \in \mathbb{Z}_n^4 \) where \( x_1 \) determines a large row (i.e., a row of subsquares), \( x_2 \) determines a row within a large row, \( x_3 \) determines a large column (i.e., a column of subsquares), and \( x_4 \) determines a column within a large column. Large rows (and rows within large rows) are labeled in increasing order from top to bottom starting with 0, while large columns (and columns within large columns) are labeled in increasing order from left to right starting with 0. Entries \( x_1 \) and \( x_2 \) together completely determine the row of a particular location; entries \( x_3 \) and \( x_4 \) do the same for the column of a particular location. Said another way, the first two coordinates of \( (x_1, x_2, x_3, x_4) \) can be viewed as a base-\( n \) representation of a row location, and the latter two coordinates as a base-\( n \) representation of a column location. For example, in Figure 1, the “4” lying in the third row and rightmost column has location \((1, 0, 2, 2)\).

Families of mutually orthogonal sudoku solutions can be characterized by sudoku arrays, which bear great similarity to ordered orthogonal arrays of type OOA\((4, s, 2, n)\). For \( n, s \in \mathbb{Z}^+ \) with \( s \geq 3 \), a sudoku array of type SA\((s, n)\) consists of an \( 2s \times n^4 \) array whose entries are drawn from an alphabet of size \( n \). Rows of the array are partitioned into \( s \) bands, each of width 2, and can be labeled lexicographically, just as for ordered orthogonal arrays. A set \( T \) of 4 rows within this array is said to be sudoku top-justified if it is top justified and, for \( i \geq 3 \), if the \((i, 1)\)-th row lies in \( T \) then the \((i, 2)\)-th row also lies in \( T \).\(^2\) Regarding a set \( T \) of sudoku top-justified rows as a sub-array of the original array, we require that each 4-tuple column of \( T \) occurs exactly once in this subarray. Rows in the top two bands of the array are called location rows. The bottom array in Figure 4 is an SA\((4, 2)\).

Consider the two sudoku solutions at the top of Figure 4. They are orthogonal, and together can be used to construct the sudoku array shown in the figure. The bold 2 and bold 3 both lie in location \((0, 0, 1, 1)\). Writing 2 and 3 in base \( n = 2 \) gives \((1, 0)\) and \((1, 1)\), respectively. If we concatenate the location and symbol data we obtain \((0, 0, 1, 1, 1, 0, 1, 1)\), and this is precisely the bold column in the sudoku array. All other columns in the sudoku array are obtained similarly: the location rows correspond to locations in a sudoku solution, while the other rows correspond to symbols expressed in base \( n \). In general we have the following analog of Theorem 1.1, part (d):

**Theorem 2.1.** Let \( s \geq 3 \). The existence of an SA\((s, n)\) is equivalent to the existence of \( s - 2 \) mutually orthogonal sudoku solutions of order \( n^2 \).

**Proof.** We describe how a set of \( s - 2 \) mutually orthogonal sudoku solutions \( \{M_1, \ldots, M_{s-2}\} \) of order \( n^2 \) implies a sudoku array \( A \) of type SA\((s, n)\); it will be apparent that this process is reversible.

Let the entry in location \(((i, k), m)\) of \( A \) be denoted \( a_{ikm} \), where \( 1 \leq i \leq s, 1 \leq k \leq 2, 1 \leq m \leq n^4 \), and \( a_{ikm} \in \mathbb{Z}_n \). According to earlier discussion, the \( n^4 \) locations of each sudoku

\(^2\)For sudoku top-justified sets \( T \): In a given band below the top two row bands, either both rows lie in \( T \), or neither of the two rows lie in \( T \).
solution can be described by $n^4$ distinct 4-tuples of the form $(a_{11m}, a_{12m}, a_{21m}, a_{22m}) \in \mathbb{Z}_n^4$. Together these 4-tuples form the first four rows (two bands) of $A$. From top to bottom these location rows will be denoted $l_{r,1}, l_{r,2}, l_{c,1}, l_{c,2}$.

Relabel the sudoku solutions so that the symbols are base-$n$ representations of the integers \{0, 1, \ldots, n^2 - 1\}. (Note that relabeling does not affect orthogonality.) Let

$$(\mu_i^1(a_{11m}, a_{12m}, a_{21m}, a_{22m}), \mu_i^2(a_{11m}, a_{12m}, a_{21m}, a_{22m}))$$

denote the symbol of $M_i$ lying in position $(a_{11m}, a_{12m}, a_{21m}, a_{22m})$ where $\mu_i^1$ is the radix digit and $\mu_i^2$ is the units digit. Then put $a_{i+2,j,m} = \mu_j^1(a_{11m}, a_{12m}, a_{21m}, a_{22m})$ for $1 \leq i \leq s - 2$. This completes the description of $A$.

To show that $A$ is a sudoku array we need to verify that every set $T$ of sudoku top-justified rows satisfies the non-repetition condition. There are several cases to consider, where $i, j$ are distinct members of \{1, \ldots, s - 2\} and $R_{i,k}$ denotes the $(i + 2, k)$-th row of $A$:

- $T = \{R_{i,1}, R_{i,2}, R_{j,1}, R_{j,2}\}$: Any repetition here indicates that the same ordered pair of symbols (one symbol from $M_i$ and another from $M_j$) appear in at least two distinct locations, contradicting the orthogonality of $M_i$ and $M_j$. (This case does not occur when $s = 3$.)
- $T = \{l_{r,1}, l_{r,2}, R_{i,1}, R_{i,2}\}$: Any repetition here implies that $M_i$ has a repeated symbol in some row, a contradiction.
- $T = \{l_{c,1}, l_{c,2}, R_{i,1}, R_{i,2}\}$: Any repetition here implies that $M_i$ has a repeated symbol in some column, a contradiction.
- $T = \{l_{r,1}, l_{r,2}, l_{c,1}, l_{c,2}\}$: Any repetition here indicates a repeated location, something that is ruled out in our hypothesis.
- $T = \{l_{r,1}, l_{c,1}, R_{i,1}, R_{i,2}\}$: Any repetition here implies repetition of a symbol within some subsquare of $M_i$, a contradiction.

We conclude that $A$ is a sudoku array. □
Observe that every ordered orthogonal array of type OOA\(_1(4, s, 2, n)\) is a sudoku array of type SA\((s, n)\), and hence every ordered orthogonal array of this type determines a collection of \(s - 2\) mutually orthogonal sudoku solutions of order \(n^2\) (Theorem 2.1). However, the reverse implication is false: for example, the array in Figure 4 fails to be an OOA\((4, 4, 2, 2)\), as can be seen by considering the set of the top rows from each of the four row bands.

3. Strongly orthogonal sudoku

Here we describe additional conditions to be imposed on a family of \(s - 2\) mutually orthogonal sudoku solutions of order \(n^2\) that are both necessary and sufficient for determining an OOA\((4, s, 2, n)\) (via the identification in the proof of Theorem 2.1). A set of mutually orthogonal sudoku solutions satisfying these additional conditions will be called strongly orthogonal.

We first introduce more terminology: If \(M\) is a sudoku solution, the corresponding radix solution, denoted \(R(M)\), consists of the radix digits of the symbols of \(M\). The radix large rows (large columns), radix subsquares, and radix rows (columns) of \(M\) are the large rows (large columns), subsquares, and rows (columns) of \(R(M)\), respectively (Figure 5). Finally, two radix solutions \(R(M_1)\) and \(R(M_2)\) may be superimposed to produce a third solution \(N_{ij}\), called a composite solution, whose symbols are ordered pairs. (These symbols may be considered numerals in base \(n\).) \(N_{ij}\) may or may not or may not be a sudoku solution (Figure 6).

![Figure 5. A sudoku solution and its corresponding radix solution.](image)

![Figure 6. Two radix solutions and the corresponding composite solution, which, in this case, is a sudoku solution.](image)

Applying the definition of top-justified (see Introduction) and extracting the sudoku top-justified rows described in the proof of Theorem 2.1 we obtain:

**Lemma 3.1.** In an SA\((s, n)\), any set of top-justified rows that is not sudoku top-justified has exactly one of the following forms listed in (1a) through (4a) below, where throughout
Let \( i, j, k, l \) are distinct members of \( \{1, \ldots, s-2\} \) and \( R_{i,1}, R_{i,2} \) are as in Theorem 2.1. The array below is merely a visual representation of the sets listed in (1a) through (4a), and no order is implied for indices \( i, j, k, l \).

\[
\begin{array}{|c|cccccccc|}
\hline
& 1a & 1b & 2a & 2b & 2c & 2d & 2e & 3a & 3b & 3c & 4a \\
\hline
\text{row} & * & * & * & * & * & * & * & & & & \\
\text{locs} & * & * & & & & & & & & & \\
\text{col} & * & * & * & * & * & & & & & & \\
\text{locs} & * & * & & & & & & & & & \\
\text{i-th band} & * & * & * & * & * & * & * & * & & & \\
\text{j-th band} & * & * & * & * & * & & & * & & & \\
\text{k-th band} & & & & & & * & & & & & \\
\text{l-th band} & & & & & & & & & & * & \\
\hline
\end{array}
\]

Further, non-repetition of 4-tuples implied by each of the applicable top-justified sets listed above is necessary and sufficient to declare an \( \text{SA}(s, n) \) to be an \( \text{OOA}(4, s, 2, n) \). (Here a top-justified set of rows is applicable if \( s \) is large enough to make its existence possible. For example, \( s \geq 5 \) is required for sets (3a) through (4a) to exist.)

Now we translate the non-repetition conditions described in Lemma 3.1 to conditions on the corresponding collection of mutually orthogonal sudoku solutions obtained from an \( \text{SA}(s, n) \) via Theorem 2.1.

**Proposition 3.2.** Let \( s, n \in \mathbb{Z}^+ \) with \( s \geq 3 \), and let \( i, j, k, l \in \{1, \ldots, s-2\} \) be distinct. A collection \( \{M_1, \ldots, M_{s-2}\} \) of mutually orthogonal sudoku solutions of order \( n^2 \) is strongly orthogonal if and only if the following conditions are satisfied for each choice of \( i, j, k, l \):

1. Whenever \( s \geq 3 \) the subsquares of \( R(M_i) \) are latin squares.
2. Whenever \( s \geq 4 \),
   a. the composite solution \( N_{ij} \) is a sudoku solution.
   b. corresponding large rows of \( R(M_i) \) and \( M_j \) are orthogonal.
   c. corresponding large columns of \( R(M_i) \) and \( M_j \) are orthogonal.
3. Whenever \( s \geq 5 \),
   a. corresponding large rows of \( N_{ij} \) and \( R(M_k) \) are orthogonal.
   b. corresponding large columns of \( N_{ij} \) and \( R(M_k) \) are orthogonal.
   c. \( N_{ij} \) and \( M_k \) are orthogonal.
4. Whenever \( s \geq 6 \) the composite solutions \( N_{ij} \) and \( N_{kl} \) are orthogonal.

**Proof.** Throughout we refer to the sets listed in Lemma 3.1. Observe that non-repetition of 4-tuples for sets of type (1a) and (1b) means that radix subsquares of \( M_i \) must be latin squares, thus yielding item (i) above. Non-repetition of 4-tuples for sets of type (2a), (2b), and (2c) says that corresponding subsquares, rows, and columns of \( R(M_i) \) and \( R(M_j) \) must
be orthogonal, respectively. In turn this means that the symbols for \( N_{ij} \) are not repeated in any subsquare, row, or column, so we obtain item (ii)(a) above. Non-repetition of 4-tuples in sets (2e) and (2f) implies that radix large rows of \( M_i \) are orthogonal to ordinary large rows of \( M_j \), and similarly for large columns, thus giving items (ii)(b) and (ii)(c) above. Non-repetition of 4-tuples for set (3a) is equivalent to requiring corresponding large rows of \( R(M_i) \), \( R(M_j) \), and \( R(M_k) \) to be orthogonal (here meaning no repetition of 3-tuples of symbols, not pairwise orthogonality). This is the same as saying that corresponding large rows of \( N_{ij} \) and \( R(M_k) \) are orthogonal, yielding (iii)(a) above. Similarly, non-repetition in set (3b) yields (iii)(b) above. Non-repetition of 4-tuples in set (3c) says that \( R(M_i) \), \( R(M_j) \), and \( M_k \) are orthogonal (again, we mean no repetition of symbol triplets), which is equivalent to requiring \( N_{ij} \) and \( M_k \) to be orthogonal, and so we obtain item (iii)(c) above. Finally, non-repetition in set (3d) says that \( R(M_i) \), \( R(M_j) \), \( R(M_k) \), and \( R(M_l) \) are orthogonal (meaning no repetition of symbol 4-tuples), and this is equivalent to requiring orthogonality of \( N_{ij} \) and \( N_{kl} \), giving item (iv) above. 

According to the proof of Proposition 3.2 any collection of corresponding radix subsquares within a set of strongly orthogonal sudoku solutions must be pairwise mutually orthogonal latin squares. Since there are at most \( n-1 \) mutually orthogonal latin squares of order \( n \), this gives a crude upper bound on the size of a strongly orthogonal family of order-\( n^2 \) sudoku solutions:

**Corollary 3.3.** The size of a strongly orthogonal family of sudoku solutions of order \( n^2 \) is no larger than \( n-1 \). Equivalently, if OOA(4, s, 2, n) exists we must have \( s \leq n + 1 \).

One consequence of Corollary 3.3 is that arrays of type OOA(4, 4, 2, 2) do not exist, so no sudoku array of type SA(4, 2), such as that shown in Figure 4, can ever be an ordered orthogonal array.

### 4. Linear sudoku and flags

Our overall goal is to construct ordered orthogonal arrays of type OOA(4, s, 2, n) by constructing a families of \( s - 2 \) strongly orthogonal sudoku solutions of order \( n^2 \). This means we want to produce a family of \( s - 2 \) pairwise mutually orthogonal sudoku solutions that satisfy the conditions listed in Proposition 3.2. In this section we introduce a framework, known as **linear sudoku**, that we will use later to construct strongly orthogonal families of sudoku solutions. Proofs have been omitted for results in this section that have been carefully described elsewhere, such as in [3] and [9].

#### 4.1. Linear sudoku

Let \( \mathbb{F} \) be the finite field of order \( q \). Hereafter all linear and matrix algebra will be performed over \( \mathbb{F} \). The set of locations within a sudoku solution of order \( q^2 \) can be identified with the vector space \( \mathbb{F}^4 \) over \( \mathbb{F} \). This identification constitutes a slight variation of that given in Section 2 where \( \mathbb{F} \) now takes the role of \( \mathbb{Z}_n \): Each location has an address \((x_1, x_2, x_3, x_4)\) (denoted \( x_1x_2x_3x_4 \) hereafter), where \( x_1 \) and \( x_3 \) denote the large row and column of the location, respectively, while \( x_2 \) and \( x_4 \) denote the row within a large row and column within a large column of the location, respectively. Rows can be labeled
in increasing lexicographic order from top to bottom starting from zero, while columns are labeled in increasing lexicographic order from left to right (see Figure 7).

|   | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
|---|---|---|---|---|---|---|---|---|
| 0 | 1 | 2 | 4 | 5 | 3 | 8 | 6 | 7 |
| 1 | 2 | 0 | 5 | 3 | 4 | 6 | 7 | 8 |
| 2 | 0 | 1 | 3 | 4 | 5 | 7 | 8 | 6 |
| 3 | 4 | 5 | 8 | 6 | 2 | 0 | 1 | 2 |
| 4 | 5 | 3 | 8 | 6 | 7 | 0 | 1 | 2 |
| 5 | 3 | 4 | 6 | 7 | 8 | 1 | 2 | 0 |
| 6 | 7 | 0 | 1 | 2 | 4 | 5 | 3 |   |

**Figure 7.** A linear sudoku solution generated by $\langle 1002, 0212 \rangle$ with asterisked symbol in location 0122.

We say that a sudoku solution is **linear** if the collection of locations housing any given symbol is a coset of some two-dimensional vector subspace of $\mathbb{F}^4$. Linear sudoku solutions come in two flavors: If every such coset originates from a single two-dimensional subspace, then the solution is of **parallel type**; otherwise the solution is of **non-parallel type**. In this article we focus only on linear sudoku solutions of parallel type, which we hereafter refer to simply as linear sudoku solutions. For example, the sudoku solution implied by Figure 7 is linear (of parallel type), generated by $g = \langle 1002, 0212 \rangle \subset \mathbb{Z}_4^3$.

In order to generate a linear sudoku solution we require that cosets of $g$ intersect each row, column, and subsquare exactly once:

**Proposition 4.1.** \([3],[9]\) A two-dimensional subspace $g$ of $\mathbb{F}^4$ generates a linear sudoku solution (up to labels) if and only if $g$ has trivial intersection with $\langle 1000, 0100 \rangle$, $\langle 0010, 0001 \rangle$, and $\langle 0100, 0001 \rangle$.

All linear sudoku solutions can be represented by $2 \times 2$ matrices. If $A, B \in M^{2 \times 2}(\mathbb{F})$ we let $\begin{bmatrix} A & B \end{bmatrix}$ denote the subspace of $\mathbb{F}^4$ spanned by the columns of the matrix $\begin{bmatrix} A \\ B \end{bmatrix}$. Also let $I$ denote the $2 \times 2$ identity matrix. In consideration of Proposition 4.1 we have the following:

**Proposition 4.2.** \([9]\) A two-dimensional subspace $g$ of $\mathbb{F}^4$ generates a linear sudoku solution (up to labels) if and only if there exists a non-lower triangular invertible matrix $\Gamma$ such that $g = \begin{bmatrix} I & \Gamma \end{bmatrix}$.

There is a simple geometric condition that characterizes orthogonality of parallel linear sudoku solutions:

**Proposition 4.3.** \([3],[9]\) Let $M_g, M_h$ be linear sudoku solutions generated by two-dimensional subspaces $g, h$ of $\mathbb{F}^4$, respectively. The two solutions are orthogonal if and only if $g$ and $h$ have trivial intersection.
Proposition 4.3 together with Proposition 4.2 imply

**Corollary 4.4.** Two-dimensional subspaces \( g_1 = \begin{bmatrix} I \\ \Gamma_1 \end{bmatrix} \) and \( g_2 = \begin{bmatrix} I \\ \Gamma_2 \end{bmatrix} \) of \( \mathbb{F}^4 \) generate orthogonal linear sudoku solutions if and only if \( \Gamma_1, \Gamma_2 \) satisfy the conditions of Proposition 4.2 and \( \det(\Gamma_1 - \Gamma_2) \neq 0 \).

### 4.2. Sudoku flags.

To produce strongly orthogonal families of sudoku solutions, it is desirable to have more control over the location of radix symbols than is provided by the linear sudoku framework presented above. (The need for control over the locations of radix symbols is evidenced by Proposition 3.2.) To place more control on the location of radix symbols, we introduce the notion of a **sudoku flag**.

Here a flag \( Z \) is a pair \((g, V)\) of subspaces of \( \mathbb{F}^4 \) where \( g \) is two-dimensional, \( V \) is three-dimensional, and \( g \subset V \). If \( Z = (g, V) \) and \( g \) generates a linear sudoku solution, then we say \( Z \) is a **sudoku flag**. Each sudoku flag \( Z \) generates a linear sudoku solution \( M_Z \), where an assignment of symbols \( \{0, 1, \ldots, q^2 - 1\} \) to locations must satisfy:

- each coset of \( g \) houses exactly one symbol, and
- each coset of \( V \) houses exactly one radix symbol.

These labeling restrictions may be rephrased as follows: symbols in \( M_Z \) lie in cosets of \( g \), while symbols in \( R(M_Z) \) lie in cosets of \( V \). If \( v_1, v_2, v_3 \in \mathbb{F}^4 \) with \( g = \langle v_1, v_2 \rangle \) and \( V = \langle v_1, v_2, v_3 \rangle \), the corresponding flag \( Z = (g, V) \) will be denoted \([v_1 \ v_2 \ v_3]\).

To illustrate a sudoku flag \( Z \) and corresponding sudoku solution \( M_Z \), let \( \mathbb{F} = \mathbb{Z}_3 \) and put

\[
Z = (g, V) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 1 & 1 & 0 \\ 0 & 2 & 2 \end{bmatrix}.
\]

Assigning the radix symbols 0, 1, 2 to the three cosets of \( V = \langle 1010, 0112, 0102 \rangle \) in \( \mathbb{Z}_3^4 \), we obtain, for example,

\[
R(M_Z) = \begin{bmatrix}
0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 \\
1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 & 0 \\
2 & 0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 \\
0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 \\
1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 & 0 \\
2 & 0 & 1 & 2 & 0 & 1 & 2 & 0 & 1
\end{bmatrix}
\]
Then we assign symbols to the cosets of $g = \langle 1010, 0112 \rangle$ in $\mathbb{Z}_3^4$, while preserving the radix symbol assignment above. For example, we obtain

$$M_\mathbb{Z} = \begin{bmatrix}
00 & 10 & 20 & 02 & 12 & 22 & 01 & 11 & 21 \\
11 & 21 & 01 & 10 & 20 & 00 & 12 & 22 & 02 \\
22 & 02 & 12 & 21 & 01 & 11 & 20 & 00 & 10 \\
02 & 12 & 22 & 01 & 11 & 21 & 00 & 10 & 20 \\
10 & 20 & 00 & 12 & 22 & 02 & 11 & 21 & 01 \\
21 & 01 & 11 & 20 & 00 & 10 & 22 & 02 & 12
\end{bmatrix}.$$

In general, such an assignment of symbols for $M_\mathbb{Z}$ is always possible because each of the $q$ cosets of $V$ is partitioned by $q$ cosets of $g$.

We present two results about sudoku flags that will be used in later sections.

**Proposition 4.5.** A flag $Z = (g, V)$ is a sudoku flag and subsquares of $R(M_Z)$ are latin squares if and only if $Z$ can be written

$$Z = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 1 \\
a & b & 0 \\
c & d & \beta
\end{bmatrix},$$

where $b$ and $\beta$ are nonzero and $\Gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ is nonsingular.

**Proof.** Applying Proposition 4.2 and column operations, $Z = (g, V)$ is a sudoku flag if and only if we can write

$$Z = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & \alpha \\
a & b & 0 \\
c & d & \beta
\end{bmatrix},$$

where $\Gamma$ is nonsingular and $b \neq 0$. To finish it suffices to show that subsquares of $R(M_Z)$ are not latin if and only if at least one of $\alpha$ and $\beta$ are nonzero. Suppose there are two distinct locations $m_1$ and $m_2$ in $R(M_Z)$ housing the same symbol and lying in the same row and subsquare. This is equivalent to the existence of $w \in \mathbb{F}_4$ and $v_1, v_2 \in V$ with $m_1 = w + v_1$, $m_2 = w + v_2$, and $m_1 - m_2 = (0, 0, 0, \mu) \in V$, where $\mu \neq 0$. The only way to obtain a vector of this form from the vectors in (1) is as a multiple of $(0, \alpha, 0, \beta)$. We conclude that $\alpha = 0$. Similarly, we the existence of two distinct locations $m_1$ and $m_2$ in $R(M_Z)$ housing the same symbol and lying in the same column and subsquare is equivalent to $\beta = 0$. \hfill \Box

Proposition 4.5 indicates that a sudoku flag giving rise to a sudoku solution with latin radix subsquares is completely determined by the datum $(\Gamma, \beta)$, where $\Gamma, \beta$ are as in the proposition.
Lemma 4.6. Suppose $V_1, V_2$ are three-dimensional subspaces of $\mathbb{F}^4$ with $V_1 + V_2 = \mathbb{F}^4$. Then $V_1 \cap V_2$ is two-dimensional and the intersection of a coset of $V_1$ with a coset of $V_2$ is a coset of $V_1 \cap V_2$.

Proof. Let $u_1 + V_1$ and $u_2 + V_2$ be cosets of $V_1$ and $V_2$. Since $V_1 + V_2 = \mathbb{F}^4$ we may assume $u_1 \in V_2$ and $u_2 \in V_1$. Put $m = u_1 + v_1 = u_2 + v_2 \in (u_1 + V_1) \cap (u_2 + V_2)$, where $v_j \in V_j$ for $j = 1, 2$.

We show that $(u_1 + V_1) \cap (u_2 + V_2) = (v_1 + v_2) + (V_1 \cap V_2)$. Let $n = u_1 + w_1 = u_2 + w_2 \in (u_1 + V_1) \cap (u_2 + V_2)$, where $w_j \in V_j$ for $j = 1, 2$. Note $n - m$ and $u_2 - v_1$ lie in $V_1 \cap V_2$, which implies

$$n = m + (n - m) = (v_1 + v_2) + [(u_2 - v_1) + (n - m)] \in (v_1 + v_2) + (V_1 \cap V_2).$$

Now suppose $n = (v_1 + v_2) + w \in (v_1 + v_2) + (V_1 \cap V_2)$ with $w \in V_1 \cap V_2$. Note $v_2 - u_1 + w$ and $v_1 - u_2 + w$ lie in $V_1 \cap V_2$, therefore

$$n = u_1 + (v_1 + (v_2 - u_1 + w)) \in u_1 + V_1 \text{ and } n = u_2 + (v_1 + (v_2 - u_2 + w)) \in u_2 + V_2.$$

Finally, the dimension formula says $V_1 \cap V_2$ is two dimensional. 

Proposition 4.7. Suppose $M_1$ and $M_2$ are orthogonal linear sudoku solutions generated by sudoku flags $Z_1 = (g_1, V_1)$ and $Z_2 = (g_2, V_2)$, respectively. If the composite solution $N_{12}$ is a sudoku solution, then it is a linear sudoku solution generated (up to labels) by the two dimensional subspace $g_{12} = V_1 \cap V_2$.

Proof. Let $b$ be a symbol in $N_{12}$ and let $b_1 b_2$ be the base-$q$ representation of $b$. Locations in $N_{12}$ housing symbols with radix digit $b_1$ are the locations in $R(M_1)$ housing the symbol $b_1$. This set of locations has the form $u_1 + V_1$ for some $u_1 \in \mathbb{F}^4$. Likewise, locations in $N_{12}$ housing symbols with units digit $b_2$ are the locations in $R(M_2)$ housing the symbol $b_2$. This set of locations has the form $u_2 + V_2$ for some $u_2 \in \mathbb{F}^4$. Therefore the set of locations in $N_{12}$ housing the symbol $b$ has the form $(u_1 + V_1) \cap (u_2 + V_2)$. Further, $V_1 + V_2 = \mathbb{F}^4$ because $M_1$ and $M_2$ are orthogonal (due to Proposition 4.3). Applying Lemma 4.6 we see that the set of locations in $N_{12}$ housing the symbol $b$ is a coset of $g_{12}$.

A computation of the intersection of the two three-dimensional subspaces of $\mathbb{F}^4$ gives the following result.

Proposition 4.8. Suppose sudoku flags $Z_1 = (g_1, V_1)$ and $Z_2 = (g_2, V_2)$, giving rise to orthogonal sudoku solutions with latin radix subsquares, possess data $(\Gamma_1, \beta_1)$ and $(\Gamma_2, \beta_2)$, respectively, with $\Gamma_i = \begin{pmatrix} a_i & b_i \\ c_i & d_i \end{pmatrix}$ for $i \in \{1, 2\}$. Further, assume $\beta_1 - \beta_2$ and $b_1(d_2 - \beta_2) - b_2(d_1 - \beta_1)$ are nonzero. Then

$$g_{12} = V_1 \cap V_2 = \begin{bmatrix} I \\ \Gamma_{12} \end{bmatrix},$$
where $\Gamma_{12} = \begin{pmatrix} a_{12} & b_{12} \\ c_{12} & d_{12} \end{pmatrix}$, and
\[
a_{12} = \frac{b_1 b_2 (c_1 - c_2) + a_2 b_1 (d_2 - \beta_2) - a_1 b_2 (d_1 - \beta_1)}{b_1 (d_2 - \beta_2) - b_2 (d_1 - \beta_1)},
\]
\[
b_{12} = \frac{b_1 b_2 (\beta_1 - \beta_2)}{b_1 (d_2 - \beta_2) - b_2 (d_1 - \beta_1)},
\]
\[
c_{12} = \frac{b_1 c_1 (d_2 - \beta_2) - b_2 c_2 (d_1 - \beta_1) + (a_2 - a_1) (d_1 - \beta_1) (d_2 - \beta_2)}{b_1 (d_2 - \beta_2) - b_2 (d_1 - \beta_1)}, \quad \text{and}
\]
\[
d_{12} = \frac{\beta_1 b_1 (d_2 - \beta_2) - \beta_2 b_2 (d_1 - \beta_1)}{b_1 (d_2 - \beta_2) - b_2 (d_1 - \beta_1)}.
\]

5. Constructing ordered orthogonal arrays

In this section we recast Proposition 3.2 in terms of sudoku flags. Then we use special collections of sudoku flags to construct families of strongly orthogonal sudoku solutions. This leads to several constructive existence theorems for ordered orthogonal arrays.

Throughout we use the notation of Section 4, and in addition we set $V_R = \langle 0100, 0010, 0001 \rangle \subset \mathbb{F}^4$ and $V_C = \langle 1000, 0100, 0001 \rangle \subset \mathbb{F}^4$. Note that $V_R$ and $V_C$ represent locations in the top large row and left large column, respectively, of sudoku solution of order $q^2$.

**Proposition 5.1.** Let $s \in \mathbb{Z}^+$ with $s \geq 3$, let $q$ be a prime power, and let $i, j, k, l \in \{1, \ldots, s-2\}$ be distinct. A collection $\{M_1, \ldots, M_{s-2}\}$ of mutually orthogonal sudoku solutions of order $q^2$, with $M_i$ arising from a sudoku flag $Z_i = (g_i, V_i)$ for each $i \in \{1, \ldots, s-2\}$, is strongly orthogonal if and only if the following conditions are satisfied for each choice of $i, j, k, l$:

(i) Whenever $s \geq 3$, each $Z_i$ is determined by datum $(\Gamma_i, \beta_i)$, with $\Gamma_i = \begin{pmatrix} a_i & b_i \\ c_i & d_i \end{pmatrix}$, as in Proposition 4.5.

(ii) Whenever $s \geq 4$,

(a) $\Gamma_{ij}$ is nonsingular and $b_{ij}$ is nonzero.

(b) The matrix $\begin{pmatrix} 1 & 1 & 1 \\ b_i & 0 & b_j \\ d_i & \beta_i & d_j \end{pmatrix}$ is nonsingular.

(c) The matrix $\begin{pmatrix} b_i \delta_i & 0 & b_j \delta_j \\ a_i \delta_i & \beta_i^{-1} & a_j \delta_j \\ 1 & 1 & 1 \end{pmatrix}$ is nonsingular, where $\delta_k = [\det \Gamma_k]^{-1}$.

(iii) Whenever $s \geq 5$,

(a) $g_{ij} \cap (V_k \cap V_R)$ is trivial.

(b) $g_{ij} \cap (V_k \cap V_C)$ is trivial.

(c) $\Gamma_{ij} - \Gamma_k$ is nonsingular.

(iv) Whenever $s \geq 6$, $\Gamma_{ij} - \Gamma_{kl}$ is nonsingular.
Proof. We obtain item (i) from the corresponding statement in Proposition 3.2 together with Proposition 4.5. Item (ii)(a) follows from the corresponding statement in Proposition 3.2 together with Propositions 4.8 and 4.2. Items (iii)(c) and (iv) are obtained from the corresponding statements in Proposition 3.2 together with Proposition 4.8 and Corollary 4.4.

For item (iii)(a), observe that large rows of $N_{ij}$ and $R(M_k)$ are orthogonal if and only if for any $v, w, z \in \mathbb{F}_4$, the cosets $v + g_{ij}$, $w + V_k$, and $z + V_R$ meet in exactly one location. By applying Lemma 4.6, this is equivalent to saying that for any $v, \tilde{w} \in \mathbb{F}_4$ we have $|(v + g_{ij}) \cap (\tilde{w} + (V_k \cap V_R))| = 1$. In turn, by Lemma 3.1 of [9], this is equivalent to $g_{ij} \cap (V_k \cap V_R) = \{0\}$. Item (iii)(b) follows similarly.

Regarding item (ii)(b), the argument for item (iii)(a) above applies to show that large rows of $R(M_i)$ are orthogonal exactly when $g_j \cap (V_i \cap V_R) = \{0\}$. Observe that

$$V_i \cap V_R = \begin{bmatrix} 0 & 0 \\ 1 & 1 \\ b_i & 0 \\ d_i & \beta_i \end{bmatrix}$$

and

$$g_j \cap V_R = \begin{bmatrix} 0 \\ 1 \\ b_j \\ d_j \end{bmatrix},$$

so that $g_j \cap (V_i \cap V_R) = \{0\}$ means $\begin{bmatrix} 1 & 1 & 1 \\ b_i & 0 & b_j \\ d_i & \beta_i & d_j \end{bmatrix}$ is nonsingular. Item (ii)(c) is verified similarly.\[\square\]

Now we turn to applications. The main goal is to produce constructive existence theorems for ordered orthogonal arrays.

5.1. Small values of $s$. Here we construct ordered orthogonal arrays of type OOA(4, $s$, 2, $q$) when $s$ is small. Throughout $s, n$ is are positive integers with $s \geq 3$, and $q$ is a prime power.

We say that a collection of $s - 2$ mutually orthogonal sudoku solutions of order $n^2$ is substrongly orthogonal if it satisfies condition (i) of Proposition 3.2 when $s \geq 3$ and also condition (ii) of Proposition 3.2 when $s \geq 4$. Via the identification given in Theorem 2.1, a substrongly orthogonal set of sudoku solutions generates a sudoku array which, in general, has some, but not all of the non-repetition properties of a true ordered orthogonal array. When $s = 3, 4$ the notions of strong orthogonality and substrong orthogonality coincide.

Theorem 5.2. Let $q$ be a prime power. The maximum (achieved) size of a substrongly orthogonal set of sudoku solutions of order $q^2$ is $q - 1$.

Proof. Let $\mathbb{F}$ denote the field of order $q$. If $q = 2$ then let $M$ be a sudoku solution of order 4 generated by the sudoku flag with data $(\Gamma, \beta)$, where

$$\Gamma = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$$

and $\beta = 1$.

The set $\{M\}$ is substrongly orthogonal (in fact strongly orthogonal) because it meets condition (i) of Proposition 3.1.
Now suppose $q > 2$ and $\alpha \in \mathbb{F}^\times$ with $\alpha \neq 1$. Let $\{M_i \mid i \in \mathbb{F}^\times\}$ be a set of sudoku solutions of order $q^2$ generated by sudoku flags with data $\{(\Gamma_i, \beta_i) \mid i \in \mathbb{F}^\times\}$ where

$$
\Gamma_i = \begin{pmatrix}
(\alpha i)^{-1} & 1 \\
0 & \alpha i
\end{pmatrix} \text{ and } \beta_i = i.
$$

Since $\Gamma_i - \Gamma_j$ is nonsingular for distinct members $i, j$ of $\mathbb{F}^\times$, the sudoku solutions $\{M_i \mid i \in \mathbb{F}^\times\}$ are mutually orthogonal according to Corollary 4.3 and they satisfy item (i) of Proposition 5.1 by construction.

Using Proposition 4.8 we see that

$$
\Gamma_{ij} = \begin{pmatrix}
0 & (1 - \alpha)^{-1} \\
\alpha^{-1} & 0
\end{pmatrix},
$$

which is nonsingular and satisfies $b_{ij} \neq 0$, thereby satisfying item (ii)(a) of Proposition 5.1. Further, items (ii)(b) and (ii)(c) of Proposition 5.1 are satisfied because the determinants of the matrices mentioned in those items, namely $\alpha(i-j)$ and $\alpha^{-1}(j^{-1} - i^{-1})$, respectively, are both nonzero. We conclude that $\{M_i \mid i \in \mathbb{F}^\times\}$ is substrongly orthogonal (of size $q - 1$).

Finally, by appealing to the proof of Proposition 3.2 corresponding order-$q$ radix sub-squares of mutually orthogonal sudoku solutions satisfying items (i) and (ii) of Proposition 3.2 must be mutually orthogonal latin squares. Such mutually orthogonal families of latin squares have size at most $q - 1$.

□

Corollary 5.3. For each prime power $q \geq 2$ there exists an OOA$(4,3,2,q)$, and for $q \geq 3$ there exists an OOA$(4,4,2,q)$.

Proof. By Proposition 5.1 any single element of a substrongly orthogonal set of sudoku solutions of order $q^2$ forms a strongly orthogonal set, as does any pair of elements. By Theorem 5.2 such single sudoku solutions exist whenever $q \geq 2$, and pairs exist when $q \geq 3$. Therefore, sudoku arrays obtained from these strongly orthogonal sets via the identification in Theorem 2.1 form an OOA$(4,3,2,q)$ and an OOA$(4,4,2,q)$, respectively. □

To illustrate Theorem 5.2 and Corollary 5.3 we put $\mathbb{F} = \mathbb{Z}_3$ and $\alpha = 2$ in the proof of Theorem 5.2. We obtain data $(\Gamma_i, \beta_i)$ for $i \in \{1, 2\}$ where $\beta_i = i$ and

$$
\Gamma_1 = \begin{pmatrix}
2 & 1 \\
0 & 2
\end{pmatrix} \text{ and } \Gamma_2 = \begin{pmatrix}
1 & 1 \\
0 & 1
\end{pmatrix}.
$$

These data correspond to sudoku flags

$$
Z_1 = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 1 \\
2 & 1 & 0 \\
0 & 2 & 1
\end{bmatrix} \text{ and } Z_2 = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 1 \\
1 & 1 & 0 \\
0 & 1 & 2
\end{bmatrix},
$$

which in turn give rise to the following strongly orthogonal pair of sudoku solutions, with symbols expressed in base 3:
Using the identification described in Theorem 2.1, solutions \(M_1\) and \(M_2\) give rise to the following OOA(4,4,2,3) (only partially shown):

\[
\begin{array}{cccccccccccccccccccc}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & \cdots \\
0 & 0 & 1 & 1 & 1 & 1 & 2 & 2 & 2 & 0 & 0 & 0 & 1 & 1 & 1 & 2 & 2 & \cdots \\
0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 & 1 & \cdots \\
0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 & 1 & \cdots \\
0 & 0 & 0 & 2 & 2 & 2 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 2 & 2 & \cdots \\
0 & 0 & 0 & 2 & 2 & 2 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 2 & 2 & \cdots \\
0 & 1 & 2 & 1 & 2 & 0 & 0 & 1 & 1 & 2 & 0 & 2 & 0 & 1 & 0 & 1 & 2 & \cdots \\
0 & 0 & 0 & 2 & 2 & 2 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 2 & 2 & \cdots \\
\end{array}
\]

5.2. Larger values of \(s\). As before, let \(q\) be a prime power and \(s \in \mathbb{Z}\) with \(s \geq 3\). For a given value of \(q\) we present values of \(s\) for which ordered orthogonal arrays of type OOA(4, s, 2, q) must exist and indicate how they can be constructed.

**Theorem 5.4.** Let \(F\) be the field of order \(q\), and let \(S \subset F^\times\) be such that if \(i, j \in S\) are distinct, then \(i + j \neq 0\) and \(ij \neq -1\). The collection of sudoku flags with data \(\{(\Gamma_i, \beta_i) \mid i \in S\}\), where

\[
\Gamma_i = \begin{pmatrix} i & 1 \\ 0 & i^{-1} \end{pmatrix}
\]

and \(\beta_i = i\),

gives rise to a strongly orthogonal collection of sudoku solutions of order \(q^2\).

**Proof.** We need to verify that this data gives rise to mutually orthogonal sudoku solutions, and that the corresponding sudoku flags satisfy the conditions of Proposition 5.1. Because \(\Gamma_i\) is nonsingular for \(i \in S\), \(\Gamma_i - \Gamma_j\) is nonsingular for distinct \(i, j \in S\), and \(b_i\) is nonzero, Proposition 4.2 and Corollary 4.4 indicate that the data give rise to a family of mutually orthogonal sudoku solutions. Further, by Proposition 4.5, condition (i) of Proposition 5.1 is satisfied, and a moment’s work shows that conditions (ii)(b) and (ii)(c) are satisfied.

The remaining conditions in Proposition 5.1 require us to observe that for distinct \(i, j \in S\),

\[
\Gamma_{ij} = \begin{pmatrix} \frac{ij}{1+ij} & \frac{ij}{1+ij} \\ \frac{1}{i+j(i+j)} & \frac{1}{i+j(i+j)} \end{pmatrix}.
\]

Observe that \(\Gamma_{ij}\) is well defined due to our hypotheses, that \(b_{ij}\) is nonzero, and that, since \(\det \Gamma_{ij} = ij \neq 0\), we know \(\Gamma_{ij}\) is nonsingular. We conclude that condition (ii)(a) of Proposition 5.1 is satisfied. Further, since \(\det(\Gamma_{ij} - \Gamma_k)\) and \(\det(\Gamma_{ij} - \Gamma_{kl})\) are

\[
\frac{(i+j)(k-i)(j-k)}{k(1+i+j)} \quad \text{and} \quad \frac{(i-k)(j-k)(i-l)(j-l)}{(1+i)(1+k+l)},
\]

respectively, we apply the hypotheses to conclude that conditions (iii)(c) and (iv) of Proposition 5.1 are satisfied.

Next, observe that $g_{ij} \cap V_R = \langle (0, 1, \frac{i}{i+j}, \frac{i+k}{i+j}) \rangle$ and $V_k \cap V_R = \langle (0, 1, k^{-1}), (0, 1, 0, k) \rangle$. Therefore $g_{ij} \cap (V_k \cap V_R)$ is trivial if and only if

$$A_R = \begin{pmatrix} 1 & 1 & 1 \\ \frac{i}{i+j} & \frac{1}{i+j} & 1 \\ \frac{k}{i+j} & \frac{k}{i+j} & k^{-1} & 1 \end{pmatrix}$$

is nonsingular. But $\det A_R = \frac{(i-k)(j-k)}{k(1+i+j)} \neq 0$ by hypothesis, hence condition (iii)(a) of Proposition 5.1 holds.

Similarly, $g_{ij} \cap V_C = \langle (\frac{1}{1+i+j}, \frac{i+j}{1+i+j}, 0, 1) \rangle$ and $V_k \cap V_C = \langle (1, -k, 0, -1), (0, 1, 0, k) \rangle$. Therefore $g_{ij} \cap (V_k \cap V_C)$ is trivial if and only if

$$A_C = \begin{pmatrix} \frac{1}{1+i+j} & 1 & 0 \\ \frac{1}{1+i+j} & -k & 1 \\ 1 & -1 & k \end{pmatrix}$$

is nonsingular. But $\det A_C = \frac{(i-k)(j-k)}{1+i+j} \neq 0$ by hypothesis, hence condition (iii)(b) of Proposition 5.1 holds.

In general, $|S| \geq q-1$ in Theorem 5.4 and $|S| \geq \frac{q}{2}$ in the special case that $q$ is a power of two. (This latter statement follows from the fact that the condition $i+j \neq 0$ always holds in characteristic two when $i, j$ are distinct.) This, together with the fact a strongly orthogonal collection of $s-2$ sudoku solutions of order $q$ determine an ordered orthogonal array of type $OOA(4, s, 2, q)$, we have the following:

**Corollary 5.5.** Let $q$ be a prime power. Ordered orthogonal arrays of type $OOA(4, s, 2, q)$ exist whenever $3 \leq s \leq \frac{q+7}{4}$, and they exist whenever $3 \leq s \leq \frac{q+4}{2}$ in the special case that $q$ is a power of two.

Observe that the proof of Theorem 5.4 assumes $|S| \geq 4$, and so is best suited for producing ordered orthogonal arrays of type $OOA(4, s, 2, q)$ where $s \geq 6$. For this reason, Corollary 5.5 does not give best results when $q$ is small (e.g., $q = 3, 4, 5$).

6. Concluding remarks

We present two concluding remarks suggesting further study: First, Corollaries 5.5 and 3.3 show that when $q$ is a prime power, the maximum value of $s$ for which $OOA(4, s, 2, q)$ exists lies somewhere between $\frac{q+7}{4}$ and $q-1$ (between $\frac{q+4}{2}$ and $q-1$ when $q$ is a power of two). It is possible that the ideas in this paper can be used to further narrow this range of maximum values for $s$. Second, our results rely heavily on the notion of sudoku flags, which suggests that, generally speaking, flag geometry may play a role in constructing ordered orthogonal arrays that is analogous to the role projective geometry (or, more properly, the geometry of Bruck nets) plays in constructing ordinary orthogonal arrays.
