Abstract

We present new spectral and photometric data of confirmed LBV star from the NGC 4736 galaxy. The star NGC 4736_1 (M_{bol} ≈ −11.5m) showed noticeable spectral variability from 2015 to 2018, which was accompanied by a significant change in the brightness. We also have estimated possible initial mass of the object NGC 4736_1 as ∼ 130 M⊙.

Key words: stars: emission lines, Be – stars: massive – galaxies: individual: NGC 4736 – stars:variables: S Doradus

1 Introduction

Luminous blue variables (LBVs) are rare type of massive stars with masses M > 25M⊙ (Humphreys et al., 2016) at one of their final evolutionary stages. These stars are characterized by a high luminosity of about ∼ 10^5 − 10^6 L⊙ (Humphreys & Davidson, 1994) and significant spectral and photometric variability at different time scales.

We present new spectral and photometric data on the LBV star NGC 4736_1 (Solovyeva et al., 2019) (12:50:57.264, +41:07:23.13) from the NGC 4736 galaxy (distance modulus of m − M = 28.31, Tully et al., 2013).

2 Data

The first spectra of the NGC 4736_1 were obtained with SCORPIO focal reducer (Afanasiev & Moiseev, 2003) on the BTA telescope of the SAO RAS on
NGC 4736 was also observed on 2018/02/18 (VPHG1200G grism) and 2020/01/18 (VPHG1200B grism). New photometric data were obtained with the BTA (2020) of SAO RAS simultaneously with spectroscopy and Zeiss-1000 (2019/04/09) of SAO RAS and also with 2.5-m telescope of the Caucasian Mountain Observatory of SAI MSU (2020/03/07). We added these data to light curve from previous work (Solovyeva et al., 2019) (see Fig. 2 left).

3 The spectral variability

The object NGC-4736 showed significant photometric variability: \( \Delta V = 1.18^{m} \pm 0.12^{m} \) and \( \Delta B = 0.90^{m} \pm 0.12^{m} \) in V and B bands (Solovyeva et al., 2019). The measurements with minimal errors were used for calculations. Based on photometric variability, spectra and luminosity NGC 4736 was concluded to be an LBV star.

The spectra of NGC 4736 obtained in 2015, shows the typical features of well-known LBV stars: broad and bright hydrogen lines, He I lines, many iron Fe II lines (figure 1) and a large number of forbidden iron lines [Fe II], [Fe III]. The spectrum obtained in 2018 has significant changes compared with the spectrum obtained in 2015: the Fe II and He I lines became indistinguishable, and the broad component of the H\(\beta\) line significantly weakened. The changes in the spectrum are accompanied by a decrease in brightness by \( \approx 1 \) mag in V band from 2015 to 2018. Such behavior means an increase in the photosphere temperature (see Figure 2 in Solovyeva et al. 2019), which is typical for LBV stars.

The spectrum obtained in 2020 does not show a changes compared to the spectrum obtained on 2018. Moreover, the photometric variability was also not detected from 2018 to 2020 (see figure 2 left panel).

The figure 2 (right panel) shows the position of NGC 4736 on the temperature - luminosity diagram. The positions of NGC 4736, NGC 4736,3 from (Solovyeva et al., 2019) are also shown. We used stellar evolutionary tracks from Tang et al. (2014) with Z = 0.01 for NGC 4736 (Pilyugin et al., 2014). Gray areas show the range of possible temperature and luminosity values of objects. The photosphere temperatures and bolometric luminosities estimates, given in Solovyeva et al. (2019), were used.

NGC 4736 has initial mass of about 130 \( M_\odot \), while NGC 4736,2 and NGC 4736,3 may have an initial mass of about 50 and 35 \( M_\odot \). A mass of 40 \( M_\odot \) is enough to pass the LBV stage (Maeder, 1996), so the star NGC 4736,3 is less luminous LBV candidate.
