Poly-trans-[(2-carboxyethyl) germasesquioxane] (Ge-132) is the most common organic germanium compound. The ingestion of Ge-132 promotes bile secretion. We assessed the rat caecal characteristics after the administration of Ge-132 and raffinose, a prebiotic oligosaccharide, because both Ge-132 and some prebiotics can change the fecal color to yellow. We also compared the changes in the caecal flora caused by the two compounds. In addition, we evaluated the simultaneous administration of Ge-132 and raffinose and their effects on β-glucuronidase activity, which is known to be a factor related to colon cancer. Male Wistar rats (three weeks old) were given one of the following diets: 1) a control diet (control group), 2) a diet containing 0.05% Ge-132 (Ge-132 group), 3) a diet containing 5% raffinose (RAF group) or 4) a diet containing 0.05% Ge-132 + 5% raffinose (GeRAF group). The Bifidobacterium, Lactobacillus and total bacteria counts were significantly increased by the dietary raffinose, and Ge-132 did not suppress this increase. The raffinose intake increased caecal acetic acid production significantly. The activity of β-glucuronidase in the caecal contents was increased by dietary Ge-132, whereas dietary raffinose decreased the β-glucuronidase activity significantly. These results indicate that the simultaneous intake of dietary raffinose and Ge-132 does not inhibit the effects of either compound on intestinal fermentation and bile secretion. Additionally, the simultaneous intake of both raffinose and Ge-132 could abrogate the increase in β-glucuronidase activity induced by Ge-132 alone.

Key words: Ge-132; organic germanium; raffinose; caecal flora; Bifidobacterium; β-glucuronidase

INTRODUCTION

Poly-trans-[(2-carboxyethyl) germasesquioxane] (Ge-132) is the most common organic germanium compound. It was first synthesized by Oikawa et al., and the structure has been previously reported [1]. Ge-132 is water soluble, and its safety has been confirmed [2]. The structures of Ge-132 and trihydroxy germyl propanoic acid, a product of the hydrolysis of Ge-132, are shown in Figure 1. Ge-132 has many therapeutic effects including anticarcinogenic and antihypertensive effects, the alleviation of rheumatism, and the prevention of hepatic disease [3–5]. Ge-132 also induces γ-interferon secretion and activates both natural killer cells and macrophages [6]. Therefore, the activation of the immune system by dietary Ge-132 can contribute to disease protection by modulating immune functions or the response to viral infections. In contrast to the benefits of Ge-132, the toxicity of germanium dioxide (GeO2), which is an inorganic germanium compound, has been described. Significant oral intake of GeO2 results in renal insufficiency due to accumulation in the kidney [7], which often causes fatal damage. We have verified that dietary Ge-132 does not accumulate or become distributed in the body [8]. Currently, germanium lactate-citrate is sold as an organic germanium formulation, but this formulation does not contain a C-Ge bond (and thus is actually inorganic germanium); therefore, it is hydrolyzed in the human body. This hydrolysis has caused fatalities after ingestion of germanium lactate-citrate [9, 10] in Europe. Because of the lack of the C-Ge bond, consumers must be careful to choose a reliable manufacturer.

Recently, Ge-132 has been used as an ingredient in health foods and supplements in Japan, Korea and the U.S.A. We observed two typical changes in the characteristics of feces after administration of Ge-132 in humans: the fecal color changed from brown to yellow, and the feces sometimes softened. The same results were observed when oligosaccharides such as raffinose...
(RAF), which is a bifidus factor that acts as a prebiotic, are administrated. These changes induce by nondigestible oligosaccharide intake are caused by modification of the microflora composition in the intestine, with the microflora becoming dominated by *Bifidobacterium* [11]. Furthermore, the isomerization of saccharides increases after the addition of the germanium compound [12]. Thus, the isomerization of saccharides into a prebiotic form in the presence of Ge-132 in the intestine was expected. It is known that starch is hydrolyzed to oligo or disaccharide like maltotriose, maltose and α-limit dextrins by α-amylase in the intestine and that maltotriose is then hydrolyzed to glucose by maltase. Glucose is transportable through the cytoplasm of the intestinal epithelium into the interstitial space by SGLT1 and GLUT5 [13]. We hypothesized that evaluation of the effects of the prebiotic RAF and Ge-132 on the caecal flora could reveal the ability of Ge-132 to promote the isomerization of some sugars, for example, hydrolysed oligo saccharides of starch, into a prebiotic sugar like fructooligosaccharide. Additionally, our collaborator manufactures dietary supplements that contain a combination of Ge-132 and RAF. Thus, we were also interested in the effect of simultaneous ingestion of Ge-132 and RAF on nutritional function.

In this study, we compared the changes in caecal characteristics after modification of the microflora composition in rats given RAF, Ge-132 or RAF and Ge-132 and evaluated prebiotic activity. Simultaneous ingestion of Ge-132 and RAF caused a decrease in the β-glucuronidase activity which occurred due to enhancement of bilirubin glucuronide by Ge-132 intake [12].

**Materials and Methods**

**Chemicals**

Ge-132 (Lot 006316A) was synthesized by the Asai Germanium Research Institute Co., Ltd. (Hokkaido, Japan), and its purity was over 99%. Raffinose (RAF) was purified to commercial grade from beet sugar by Nippon Beet Sugar Mfg. Co., Ltd. (Hokkaido, Japan). Solvents and chemicals were purchased from Wako Pure Chemical Industries, Ltd. (Osaka, Japan). Agar media and its components were purchased from Difco of Becton, Dickinson and Company (Franklin Lakes, NJ, U.S.A.), Nissui Pharmaceuticals Co., Ltd. (Tokyo, Japan) and Kyokuto Pharmaceutical Industrial Co., Ltd. (Tokyo, Japan). *P*-nitrophenyl-β-D-glucuronide was purchased from Sigma-Aldrich (St. Louis, MO, U.S.A.).

**Animals and diets**

Male Wistar rats (three weeks old, Japan SLC, Shizuoka, Japan) were housed in a room with controlled temperature (22-25°C) and light (08:00 to 20:00) conditions. After the rats were acclimated for 1 week, they were randomly divided into four groups (5 rats each) for two weeks and maintained on one of the following diets: a control diet (Control group), a 0.05% Ge-132 diet (Ge-132 group), a 5% RAF diet (RAF group) or a 0.05% Ge-132 + 5% RAF diet (GeRAF group). The number of rats per group was based on that used in a previous study at our laboratory (not published), which showed significant differences in the prebiotic effect of RAF administration. The rats could eat and drink water freely throughout the experiment, which lasted 2 weeks. The composition of each diet is shown in Table 1. The diets were prepared based on the AIN-76 composition. The dosage of Ge-132 was determined based on the daily intake of Ge-132 (500 mg/adult) that causes changes in the fecal color of adult humans, while the dosage of RAF was determined based on the amount needed to beneficially enhance *Bifidobacterium* levels. These components took the place of cornstarch as the primary ingredient or carbohydrate. On the final day, the animals were anaesthetized using pentobarbital and euthanized by bleeding from the abdominal aorta. The major organs and the caecum were then excised and used for immediate analysis.

**Ethics**

This animal experiment was conducted at the Asai Germanium Research Institute Co., Ltd., according to the guidelines provided by the ethics committee for experimental animal care, which are based on the public
guidelines set by the Japanese Ministry of Education, Culture, Sports, Science and Technology.

**Caecal microflora analysis**

Fresh caecal contents (0.5 g) were collected and transferred to 4.5 g of prereduced phosphate-buffered saline containing 0.1% (w/v) purified agar and 0.05% (w/v) cysteine-HCl. Samples were suspended in dilution buffer, and 10-fold serial dilutions from 10^-1 to 10^-8 were prepared. From the appropriate dilutions, 0.05 ml aliquots were spread onto agar plates. The methods for bacterial analysis of the caecal microflora content have been previously reported [14, 15]. The following 3 nonselective and 6 selective agar media were used to isolate the caecal microflora: modified Eggerth-Gagnon (EG) agar or glucose-liver-blood (BL) agar with 5% horse blood for facultative anaerobes, Trypticase soy (TS) agar for total aerobes, *Bifidobacterium*-selective (BS) agar for *Bifidobacterium, Eubacterium*-selective (ES) agar for eubacteria, modified Veillonella-selective (VS) agar for *Veillonella*, modified Lactobacillus-selective (LBS) agar for *Lactobacillus*, deoxycholate-hydrogen sulphate-lactose (DHL) agar for enteric bacteria and triphenyltetrazolium chloride-acridine orange-thallous sulphate-esculin-crystal violet (TATAC) agar for *Enterococcus* and *Streptococcus*. The aerobes were cultured for 24 hr at 37°C, and the anaerobes were cultured for 72 hr at 37°C in anaerobic jars using the steel wool method [16]. The reduced steel wool was placed in a jar with the culture plates, and the atmosphere was replaced with CO2. Each colony was separated from the culture and spread onto a glass slide for microscopic examination. The slides were stained with Gram stain solution. The log numbers of bacteria in the caecal contents were calculated.

**Analysis of organic acids in caecal contents**

The caecal contents (0.2 g) were weighed and mixed with 1 ml of Sorensen’s phosphate buffer (pH 7.4), and 0.1 ml of 0.1 N HCl was then added to the mixture. Pyroglutamic acid was used as the internal standard. Prepared samples were analyzed by HPLC with UV detection after filtration. The analytical column was a two-jointed Shodex Ionpak KC-811 column (4.6 × 150 mm, 5 μm, Showa Denko K.K., Tokyo, Japan). The mobile phase was 2 mM perchloric acid, and the flow rate was 1 ml/min. The post-column method was used with bromothymol blue as the pH indicator at a flow rate of 0.5 ml/min [11]. The eluted sample was analyzed at 445 nm.

**Assay of β-glucuronidase activity in caecal contents**

The activity of β-glucuronidase was measured as previously reported by Ishikawa et al. [17]. An eighty-fold dilution of the caecal contents was used as the enzyme solution. The substrate solution (180 μl), which consisted of 0.1 M phosphate buffer (pH 7.4) containing 4 mM p-nitrophenyl-β-D-glucuronide (Sigma-Aldrich, St. Louis, MO, U.S.A.) and 0.133 mM Na-EDTA, was added to the enzyme solution (60 μl). The reaction mixture was incubated for 20 min at 37°C, and the reaction was stopped by the addition of 240 μl Na2CO3. The mixture was centrifuged, and the amount of p-nitrophenol in the supernatant was quantitated by measuring the absorption at 415 nm.

**Data analysis**

All values are presented as the means and standard deviations of 5 rats. Statistical comparisons among the groups were performed using analysis of variance (ANOVA). Data were processed with two-way factorial ANOVA. Statistical significance was defined as p<0.05. Data for bacterial numbers with a detection rate of 100% were processed with ANOVA. The Statcel-The Useful Addin Forms on Excel software, 2nd edition (published by OMS Ltd., Saitama, Japan), was used for all statistical analyses.

**RESULTS**

**Effects on the fecal characteristics and the caecal flora composition**

The weights of the major organs are shown in Table 2. Dietary Ge-132 had no effect on the tissue weights, whereas dietary RAF increased the weights of both the

(%)
caecal contents ($p = 5.7 \times 10^{-9}$) and the caecal wall ($p = 5.7 \times 10^{-6}$). The caecum was expanded by dietary RAF. The components of the caecal microflora from rats that received the four different diets are shown in Table 3. The RAF-containing diet resulted in a significantly higher ($p = 2.6 \times 10^{-6}$) total bacterial number in the rats. The total bacterial number was greater in the GeRAF rats (10.2 log10 bacteria/g of caecal content) and RAF (10.3) rats than in the control (9.8) rats, whereas dietary Ge-132 did not change the number of bacteria (9.6). When the rats ingested dietary RAF, the frequency of detection of *Bifidobacterium* changed from 20% to 100%. The detection frequencies were calculated based on the detection of colonies forming on cultured agar plates; a lack of colony formation from a 10^-6 diluted solution was treated as not detected (N.D.). Dietary RAF increased the number of *Bifidobacterium* cells relative to the control (control=9.0 vs. RAF=10.1 and GeRAF=10.1); in contrast, the numbers of other species of microorganisms, especially Bacteroidaceae ($p=0.026$) and Enterobacteriaceae ($p=0.001$), decreased. The number of total aerobes was significantly decreased by the RAF ($p=0.027$). Some anaerobes, including *Bifidobacterium*, *Lactobacillus* and *Veillonella*, increased in number with dietary RAF treatment, and the detection frequencies of *Clostridium* changed from 20% to 100% in rats that ingested RAF. *Lactobacillus* was increased by the RAF-containing diet ($p=0.018$).

**Apparent change in the caecum induced by the intake of RAF and Ge-132**

Images of the rat caeca after administration of each diet for 2 weeks are shown in Fig. 2. The caecal sizes of the rats in the RAF-containing diet groups (RAF and GeRAF) were larger than the caecal sizes of the rats in the control and Ge-132 groups. In contrast, rats that were fed the diet containing Ge-132 exhibited no change in the size of the caecum. In addition, the caeca of the rats

The detection rates of colonies on five culture dishes are shown in parentheses.
The species that formed no colonies on cultured plates are shown as not detected (N.D.).
Each species with no N.D. data was subjected to statistical analysis by two-way factorial ANOVA ($p<0.05$).
GE, RAF and GexRAF show the main effect of Ge-132, main effect of RAF and interaction of Ge-132 and RAF, respectively.
treated with Ge-132 (Ge-132 and GeRAF) turned yellow. Dietary RAF alone had a slight influence on the color of the caecum, making the color slightly yellowish.

**Caecal pH and organic acids in the caecal contents**

The caecal pH and organic acids in the caecal contents are shown in Table 4. Dietary Ge-132 did not change the pH; however, dietary RAF significantly \((p = 2.8 \times 10^{-5})\) reduced the pH relative to the control: control pH = 7.5, RAF pH=6.2 and GeRAF pH=6.1. The intake of Ge-132 decreased lactic acid from 0.430 to 0.192 \((p=0.036)\). However, there was no effect on the level of any other organic acid or on the pH in rats fed a diet with Ge-132. In contrast, the caeca of rats fed a diet containing RAF showed an increase \((p = 0.040)\) in the concentration of acetic acid (1.9 to 2.8 μg/g caecal content) relative to the caeca of rats fed other diets, and the levels of formic acid

\[\text{were increased from 0.003 to 0.062 μg/g caecal content (} p=0.035\) by the RAF. On the other hand, n-butyrlic acid, i-valeric acid and n-valeric acid were decreased from 0.513 to 0.330 μg/g caecal content \((p=0.001)\), from 0.154 to 0.081 μg/g caecal content \((p=0.007)\) and from 0.193 to 0.032 μg/g caecal content \((p=1.6 \times 10^{-6})\) by the RAF, respectively.

**β-Glucuronidase activities of the caecal contents**

The β-glucuronidase activities in the caecal contents of the rats that were fed the four diets are shown in Table 5. Dietary Ge-132 marginal significantly \((p=0.051)\) enhanced the β-glucuronidase activity from 1.6 to 2.6 units/g caecal content, but the two RAF-containing diets, RAF and GeRAF, resulted in significantly reduced the β-glucuronidase activity \((p=6.4 \times 10^{-7})\), to 0.4 and 0.3 units/g. Additionally, the activities measured in the other two units (units/caecum and units/10^{10} bacterium) showed no significant differences for the rats fed diets with Ge-132. The activities, measured in units/caecum, were 3.6 for the control diet, 5.2 for the Ge-132 diet, 2.2 for the RAF diet and 2.0 for the GeRAF diet, whereas the activities as measured in units/10^{10} bacteria were 3.3 for the control diet, 7.0 for the Ge-132 diet, 0.2 for the RAF diet and 0.2 for the GeRAF diet. RAF significantly decreased the activity measured by both methods \((p=0.001)\). The interaction of GE × RAF was evaluated. A significant difference \((p=0.032<0.05)\) was found in units/g caecal content.

### DISCUSSION

In this study, we evaluated the effects of Ge-132 and RAF on caecal characteristics. We confirmed that RAF can abrogate the high β-glucuronidase activity induced by Ge-132 intake.

P values were obtained from two-way factorial ANOVA \((p<0.05)\).
GE, RAF and GexRAF show the main effect of Ge-132, main effect of RAF and interaction of Ge-132 and RAF, respectively.
We previously reported that dietary Ge-132 promotes bile secretion, and we demonstrated that the fecal color change due to dietary Ge-132 was induced by bile pigment and porphyrin [18, 19]. However, we did not determine the pigments present in the caecal contents in this study because the change in the microflora composition is more important than the color change. We examined the composition of caecal microorganisms to determine if RAF can promote an increase in *Bifidobacterium* populations. Additionally, we evaluated the effect of Ge-132 intake on the caecal flora. RAF is one of the most common bifidus factors, and our collaborators observed this result in previous studies of RAF intake in humans and mice [11, 20, 21]. In this study, RAF enhanced the detection frequency of *Bifidobacterium*; this phenomenon was not unexpected because the bacterial number was enhanced by fermentation with RAF, and the increase in the volume of the caecal contents increased the size of the caeca, as shown in Fig. 2 and Table 2. In contrast, dietary Ge-132 did not change the composition of the caecal flora. One of aim of this study was to evaluate if the sugar isomerization induced by Ge-132 affects caecal fermentation. The results show that Ge-132 did not affect the isomerization of saccharides that originated from hydrolysis of starch and have a prebiotic effect in the intestine. However, the fecal color change induced by Ge-132 intake was not related to the differences in the microflora (between the control group and the Ge-132 group). This result is in agreement with a previous report [18]. It suggests that fecal color change caused by the Ge-132 intake did not occur due to the prebiotic effect but from bile pigment induction.

*Bifidobacterium* was increased predominantly by the RAF treatments. The same prebiotic effect has been previously reported in different animal species [11, 21]. Additionally, the predominant species changed from Bacteroidaceae to *Bifidobacterium* with decrease in Bacteroidaceae due to the RAF intake. *Lactobacillus* also increased, while Enterobacteriaceae were decreased by the RAF intake. In contrast, the frequencies of the detection of *Clostridium* and *Veillonella* were higher in the RAF group than in the control group. Generally, *Clostridium* and *Veillonella* are categorized as bad or harmful bacteria. Infection with them sometimes triggers diseases. In this study, we observed an increase in them on intake of RAF and GeRAF. The frequencies of detection of *Clostridium* increased from 0% to 100 and 60%, respectively. However, the number of bacteria for the Control, RAF and GeRAF were similar. In this study, we observed an increase in some species of *Veillonella* on intake of RAF and GeRAF. These increases might not have occurred due to direct utilization of RAF. This is probably a reason why the number of *Veillonella* is low compared with the total number of bacteria or *Bifidobacterium* cells in the RAF and GeRAF groups. However, this may suggest that some strains of *Veillonella* can utilize RAF. Dietary RAF intake decreased Bacteroidaceae and Enterobacteriaceae, while the populations of *Bifidobacterium* and *Lactobacillus* increased. The prebiotic effect of RAF was confirmed. In this study, there was an apparent difference in the effects of Ge-132 intake and RAF intake on microflora. Therefore, we think that the fecal color change resulting from Ge-132 intake was not influenced by microflora. However, the frequencies of detection in some species were low, and they demand a detailed experiment with a large number of animals per group.

RAF is fermented by *Bifidobacterium* and *Lactobacillus*, and the caecal pH was lowered by RAF and GeRAF. Generally, fermentation produces organic acids, and this increase in organic acids lowers the pH of

| β-Glucuronidase activity in | Control | Ge-132 | RAF | GeRAF | P value |
|-----------------------------|---------|--------|-----|-------|---------|
| **Units/g caecal content**  | 1.6 ± 0.8 | 2.6 ± 0.6 | 0.4 ± 0.2 | 0.3 ± 0.2 | 0.051 6.4E-07 0.032 |
| **Units/caecum**            | 3.6 ± 1.6 | 5.2 ± 1.0 | 2.2 ± 1.0 | 2.0 ± 1.3 | 0.228 0.001 0.130 |
| **Units/10^10 bacteria**    | 3.3 ± 2.8 | 7.0 ± 4.5 | 0.2 ± 0.1 | 0.2 ± 0.1 | 0.139 0.001 0.165 |

Values are means ± SD.
P values were obtained from two-way factorial ANOVA (p<0.05).
GE, RAF and GeRAF show the main effect of Ge-132, main effect of RAF and interaction of Ge-132 and RAF, respectively.
the caecal contents. In this study, a significant increase in the amounts of acetic acid and formic acid were observed. We found an approximately 1.6-fold increase in acetic acid production in the caecal contents of the RAF-treated groups (Table 4). Acetic acid was the most abundant organic acid and showed a significant increase in both RAF-treated groups; thus, the lower pH may be the result of the increase in the amount of acetic acid. In recent studies, probiotics have been shown to protect the intestinal tract from lethal infectious diseases [24]. Some probiotics can produce large amounts of acetic acid, and this ability is critical for the defence against pathogens. In this study, the increase in the populations of *Bifidobacterium* and *Lactobacillus* caused by RAF and GeRAF increased the levels of acetic acid in the intestine; thus, we are interested in a resistant effect against infection. To test this hypothesis, future experiments should be performed with more animals per group and with a pathogen infection model. We previously described the increase in bilirubin glucuronide in the intestine induced by Ge-132 and a corresponding increase in $\beta$-glucuronidase activity [18]. $\beta$-glucuronidase activity is known to be a risk factor for colon cancer [25-27]; therefore, the enhancement of $\beta$-glucuronidase activity is not a desirable result. Some prebiotic oligosaccharides can reduce $\beta$-glucuronidase activity [28-31]. Therefore, we wanted to determine if the simultaneous intake of RAF could suppress the increasing levels of $\beta$-glucuronidase activity induced by Ge-132. Except for an increase in the amount of *Bifidobacterium*, RAF reduced the amount of microorganisms in the caeca (Table 3); thus, the $\beta$-glucuronidase activity was low (Table 5). RAF increased the volume of the intestinal contents and the caecal contents, as shown in Fig. 2 and Table 3. The enzyme was diluted by the increased content of the microorganisms, as demonstrated by the lack of a decreased in the activity as measured relative to the whole caecum (Table 5). Some probiotics such as the lactic acid bacteria *Bifidobacterium* and *Lactobacillus* can reduce intestinal $\beta$-glucuronidase activity [32-34]. It has been reported that some strains of *Bacteroides* and *E. coli* lead to higher levels of $\beta$-glucuronidase activity [35, 36]. In this study, RAF acted as a prebiotic and enhanced the lactic acid bacteria while suppressing the enterobacteriaceae, and $\beta$-glucuronidase activity might be reduced. In contrast, Ge-132 enhanced the activity of $\beta$-glucuronidase in the caecal contents (Table 5). However, the populations of intestinal bacteria did not change. Thus, the increase in $\beta$-glucuronidase activity induced by Ge-132 is not related to the bacterial balance. Moreover, there was a significant difference in interaction caused by the GeRAF intake. The data suggest that if glucuronidase does increase the risk of cancer, simultaneous intake of RAF could abrogate this risk. In this study, Ge-132 and RAF did not inhibit each other’s functions. The effect of the hypothesized promotion of the isomerisation of saccharides into prebiotics in the intestine by Ge-132 seems too little to change the microflora. However, the evaluation of this conversion requires examination in a study that does not need to consider intestinal absorption, such as an analysis of saccharides for culture of cecal contents with Ge-132. In contrast, enhanced acetic acid production and lower pH in the caecal contents due to RAF intake were confirmed. This change may protect against pathogenic infections. Moreover, the simultaneous intake of Ge-132 and RAF suppressed $\beta$-glucuronidase activity, and this activity increased when the rats were fed a diet containing only Ge-132. In this study, this was the only beneficial effect found for simultaneous intake of Ge-132 and RAF. We recently revealed a symbiotic effect of Lactobacilli, oligosaccharide and Ge-132 on immune response in mice [37]. Both Ge-132 and RAF have immune activation activity; therefore, the potential for immune modulation by this combination of supplements is interesting. Further research is needed to test this speculation.

ACKNOWLEDGMENTS

We are very grateful to Dr. Taro Kishida, Department of Applied Biosciences at Ehime University, for technical guidance on the rat experiments, and we thank Dr. Mitsuo Akiba, Tokyo University of Pharmacy and Life Sciences, for his beneficial advice concerning this study.
