ON DIVISORIAL \((i)\) CLASSES

OLIVIA DUMITRESCU AND NATHAN PRIDDIS

Abstract. In this paper we introduce and study divisorial \((i)\) classes for the blow up of projective space \(\mathbb{P}^n\) in several points for \(i \in \{-1,0,1\}\). We generalize Noether’s inequality, and we prove that all divisorial \((i)\) classes are in bijective correspondence with the orbit of the Weyl group action on one exceptional divisor following Nagata’s original approach. Moreover, we prove that the irreducibility condition from the definition of divisorial \((i)\) classes can be replaced by the numerical condition of having positive intersection with all divisorial \((i)\) classes of smaller degree via the Mukai pairing.

Introduction

In this article, we generalize several important results about the blow up of \( \mathbb{P}^n \) in several points. As motivation, let us recall one of Hilbert’s problems.

0.1. Hilbert’s 14th problem. In 1900 Hilbert posed 23 problems at the International Congress of Mathematicians in Paris. Hilbert’s fourteenth problem encountered several modifications and generalizations in the subsequent years, one of them due to Zariski in 1953 [44]. The original formulation of the conjecture (following Nagata [37]) is as follows.

Problem 0.1. Let \( K \) be a field and \( G \) a subgroup of the linear group \( GL(s, K) \), acting via automorphisms on the polynomial ring \( K[x_1, \ldots, x_s] \). Is the invariant ring \( K[x_1, \ldots, x_s]^G \) finitely generated over field \( K \)?

The answer of this problem was proven in the affirmative in the following cases:

- \( K = \mathbb{C} \) and \( G = SL(s, K) \) (Hilbert).
- \( G \) a finite group and \( K \) arbitrary (Emmy Noether).
- \( K = \mathbb{C} \) and \( G \) a one parameter group (Weitzenböck).
- \( K = \mathbb{C} \) and \( G \) a connected semi-simple group (H. Weyl).

In 1958 Masayoshi Nagata gave a counterexample to Hilbert’s 14th problem (see [34] and [35]) by considering the standard unipotent linear action of \( C^s \) on the polynomial ring in \( 2s \) variables \( S = \mathbb{C}[x_1, \ldots, x_s, y_1, \ldots, y_s] \)

\[(t_1, \ldots, t_s) \cdot (x_1, \ldots, x_s, y_1, \ldots, y_s) = (x_1, \ldots, x_s, y_1 + t_1 x_1, \ldots, y_s + t_s x_s) \]

One of the major breakthroughs of Nagata was to show that if \( G = G_{13} \subset C^s \), then the invariant ring \( S^G \) is isomorphic to the Cox ring of the blow up \( X_{s-1, s} \), \( S^G \cong \text{Cox}(X_{s-1, s}) \) (see Section 1.1). In [36, Theorem 2a] Nagata proves that on \( X_{2, 16} \) there exists a bijection between \((-1)\) curves (what Nagata calls irreducible exceptional curves of the first type) and the orbit of the Weyl group under the class of an exceptional divisor (what Nagata calls pre-exceptional type of first kind).

In particular, he proved that if \( G = G_{13} \), the general linear group in \( C^{16} \), the invariant ring \( S^G \) is not finitely generated. This is due to the fact that there are an infinite number of \((-1)\) curves in the Picard group of the blow up of \( \mathbb{P}^2 \) in 16 general points (which we will denote by \( X_{2, 16} \)), or equivalently that the orbit of the Weyl group \( W_{2, 16} \) on one exceptional divisor in \( X_{2, 16} \) is not finitely generated. We will discuss this more below.

This theme of research was continued by Mori and led to the development of the Minimal Model Program and to the identification of Mori Dream Spaces: those for which the Cox ring is finitely generated, as presented in Section 1.1. In Section 5 we generalize Nagata’s approach to higher dimensions.

Next, we define the main characters in this paper and set some notation.

Notation 0.2. Let \( X_{n,s} \) denote the blowup of \( \mathbb{P}^n \) in a collection of \( s \) points \( p_1, \ldots, p_s \) in general position. The Picard group is generated by \( \text{Pic} X_{n,s} = \langle H, E_1, \ldots, E_s \rangle \), where \( H \) is a general hyperplane in \( \mathbb{P}^n \) and \( E_i \) is the exceptional divisor corresponding to the point \( p_i \). A general divisor \( D \in \text{Pic} X_{n,s} \) can be written in terms of degree \( d \) and multiplicities \( m_i \):

\[(0.1) \quad D = dH - \sum_{i=1}^{s} m_i E_i.\]
0.2. Main results. The main goal of this paper is to develop the techniques to prove that the \((i)\) Weyl divisors are equivalent to divisorial \((i)\) classes defined by algebraic equations (0.2).

Laface and Ugaglia introduced the concept of \((-1)\) classes in [25], where they also study properties of the Dolgachev-Mukai form. Furthermore, we have used the term divisorial \((i)\) classes to emphasize that they are divisors.

**Definition 0.3.** (see also Definition 3.1) For \(i \in \{-1, 0, 1\}\), we introduce the concept of divisorial \((i)\) class on \(X_{n,s}\) as an effective and irreducible divisor of the form (0.1) satisfying following numerical conditions

\[
(n - 1)d^2 - \sum_{i=1}^{s} m_i^2 = i,
\]

and

\[
d(n + 1) - \sum_{i=1}^{s} m_i = 2 + i.
\]

We also define \((i)\) Weyl divisors to be Weyl group orbit of a general hyperplane passing through \(n - 1 - i\) points.

Mukai introduced the notion of \((-1)\) divisors (see Definition 3.6). In the planar case, the notion of \((-1)\) divisor and divisorial \((-1)\) class is the same with \((-1)\) curve by Lemma 1.7, but this is not true in higher dimension. Throughout the paper we emphasize similarities and differences between the two-dimensional and \(n\)-dimensional cases, allowing us to conclude that the definition of divisorial \((i)\) classes is a natural generalization of \((i)\) curves that is been exploited in its full generality in this paper.

**Notation 0.4.** Let \((\langle, \rangle)\) define the Dolgachev-Mukai pairing on \(\text{Pic}(X_{n,s})\) (see Equation (2.4)). By abuse of notation we use the terminology self-intersection of a divisor \(D\) on \(\text{Pic}(X_{n,s})\) to denote \(\langle D, D \rangle\). We also use terminology anticanonical degree of the divisor \(D\) to denote intersection of \(D\) with the anticanonical divisor (see Equation (2.2)) rescaled by a factor of \(1/(n-1)\),

\[
\text{adeg}(D) := \frac{1}{n-1}\langle D, -K_{X_{n,s}} \rangle.
\]

Finally, we use degree for the intersection of \(D\) with a general hyperplane class \(H\)

\[
\text{deg}(D) := \langle D, H \rangle
\]

to denote the regular degree of the hypersurface defined by \(D\). As in the description of divisorial \((i)\) classes above, these can be given numerically in terms of \(d\) and \(m_i\); the first equation of (0.2) says \(\langle D, D \rangle = i\) and the second is \(\text{adeg}(D) = 2 + i\).

The main results of this article are the following three theorems. The first of these theorems, which we prove in Section 4, generalizes the Max Noether inequality for \((-1)\) curves on \(X_{2,s}\) to divisorial \((i)\) classes (in higher dimensional spaces, i.e. \(n \geq 2\)) for \(i \in \{-1, 0, 1\}\).

There is a certain basis of the orthogonal complement of the canonical class \(K_{X_{n,s}}\), which we denote by \(\alpha_1, \ldots, \alpha_s\) (see Section 2.2 for a definition of these classes). With this basis, we can state the theorem as follows:

**Theorem 0.5.** Let \(D\) be a divisor with \(d \geq m_i \geq 0\) satisfying \(\text{adeg}D = c + 2\) and \(\langle D, D \rangle = c + e\) for two integers \(c\) and \(e\) satisfying \(-2 \leq c, e \leq 1.\) If \(d = 1\) further
assume that $\langle D, D \rangle < 0$. Then we can reorder the indices so that $\langle D, \alpha_k \rangle \geq 0$ for any $1 \leq k \leq s - 1$ and $\langle D, \alpha_s \rangle < 0$.

If $e = 0$ then the theorem states that any $i$ divisorial class (irreducible or not) is not Cremona reduced for every $-1 \leq i = c \leq 1$. One may notice that the assumptions in Theorem 0.5 are weaker than the assumptions in the original theorem by Max Noether (see e.g. [16] and Remark 4.3). The original Max Noether inequality requires the curve $C$ to be rational and $-2 \leq \langle C, C \rangle \leq 1$. This is equivalent to saying adeg $C = 2 + c$. Therefore we deduce that we can apply Max Noether inequality for all $(i)$ curves with $-1 \leq i = c \leq 1$.

The second result, which we prove in Section 5 is a generalization of a result discovered by Nagata in [36] (and reformulated by Dolgachev in [13]). Namely Nagata’s original approach extends to $(i)$ Weyl divisors in $X_{n,s}$ giving a correspondence between divisorial $(i)$ classes and $(i)$ Weyl divisors, as follows:

**Theorem 0.6.** Let $D$ be a divisor in $\text{Pic}(X_{n,s})$. Then $D$ is a divisorial $(i)$ class if and only if it is a $(i)$ Weyl divisor. In particular, the Weyl group acts transitively on the set of divisorial $(i)$ classes.

Laface and Ugaglia gave an alternate proof only when $i = -1$ in [25] via different methods. However, until now, we did not realize the importance of divisorial $(0)$ divisors and divisorial $(1)$ divisors. They are important because they give faces of Mori cone of curves. Indeed, let $\mathcal{Z}_{\geq 0}$ as the cone of curve classes in $A^{r-1}(X_{n,s})$ that meet all $(0)$-divisorial classes non-negatively. Further, define $\mathcal{Z}_{\geq 0}(\langle -1 \rangle)$ to be the cone generated by $\mathcal{Z}_{\geq 0}$ and all $(\langle -1 \rangle)$-curves in $X_{n,s}$. Theorem 0.6 further implies the following Corollary, which also appeared in [15], as an application of this work.

**Corollary 0.7.** The cone of classes of effective curves in $X_{n,s}$ is a subcone of $\mathcal{Z}_{\geq 0}(\langle -1 \rangle)$.

As a corollary, we also generalize a result of Dolgachev regarding rational curves with self-intersection $-2$ from the two-dimensional to $n$-dimensional space.

**Corollary 0.8.** There are no irreducible divisors $D$ on $X_{n,s}$ with $\langle D, D \rangle = r \in \{-4, -3, -2\}$ and adeg$(D) = -2 - r$.

Finally, we prove that the irreducibility criterium of Definition 3.1 can be replaced by a numerical condition based on intersection of divisors with smaller degree, as was done for $n = 2$ in [13]. In the case of planar curves, Theorem 0.9 generalizes the main result in [13] answering a question of Harris from $i = 1$ to $i = 1, 0, 1$. Moreover, the statement is true for divisorial $(i)$ classes in arbitrary dimension. This is done in the following theorem, which we prove in Section 6.

**Theorem 0.9.** Take $i \in \{-1, 0, 1\}$. The divisor $D$ is a divisorial $(i)$ class on $X_{n,s}$ if and only if $D$ is effective satisfying numerical conditions (0.2) and for all degrees $0 < d' < d$ and all divisorial $(\langle -1 \rangle)$ classes $D'$ of degree $d'$ we have $\langle D, D' \rangle \geq 0$.

The remainder of the paper is organized as follows. In Section 1 we recall $(-1)$ curves on blown up projective planes. In Section 2 we recall Cox rings, standard Cremona transformation, define the Weyl group, and discuss the Dolgachev-Mukai pairing. In Section 3 we introduce divisorial $(i)$ classes on blown up projective spaces in $s$ general points as effective, irreducible divisors with self-intersection $(i)$ and intersection with anti-canonical degree equal to $2+i$ with respect to Dolgachev-Mukai pairing (see Definition 3.1). In Section 7 we describe divisorial $(-1)$ classes
for Mori Dream Spaces and a relationship between $X_{n,n+3}$ and the moduli space of certain rank two vector bundles over $\mathbb{P}^1$. Finally, as mentioned above, Sections 5, 4, 6 contain the proofs of Theorems 0.5, 0.6, and 0.9, resp.

0.3. Recent work. This paper served as main example and motivation in the recent development of $(-1)$ curves in higher codimension: for example $(-1)$ curves in $X^n_3$ were defined and computed in [14], while Weyl surfaces in $X_{4,8}$ were defined and computed in [15] and [6].

In this paper we emphasize that Nagata’s equivalence between $(-1)$ curves and $(-1)$ Weyl lines is part of the complex framework of Coxeter group theory. In particular, the tools used in this paper for divisors in $X_{n,s}$ were generalized to the theory of curves in $X_{n,s}$. The Coxeter group theory comes equipped with a bilinear form that induces a bilinear form on the space of divisors and curves ie on $A^{n-1}(X_{n,s})$ and $A^{n-1}(X_{n,s})$ [15] (in the planer case the bilinear form the intersection product on $X_{2,s}$). The bilinear form on divisors is called in the literature Dolgachev-Mukai form (Notation 0.4 (,)). Numerically, $(-1)$ Weyl line classes $c$ can be defined via a linear and quadratic invariant, similar to 0.2, coming from self-intersection of the class $c^2$ and the intersection of $c$ with the anti-canonical curve class via the bilinear form of the Coxeter theory. In Mori Dream Spaces and $X_{5,9}$ the $(-1)$ curves are equivalent to $(-1)$ Weyl lines and $(-1)$ Weyl line classes ie lines through two points together with the rational normal curve of degree $n$ passing through $n + 3$ points in [15, Theorem 1.3]. Moreover, (0) and (1) Weyl lines give extremal rays for the cone of movable curves - defining faces of the Effective cone of divisors for Mori Dream Spaces $X_{n,s}$, [15, Theorem 1.4]. The infinity of (1) Weyl lines reproves the result of Mukai that $X_{n,s}$ is not a Mori Dream Space when $(K_{X_{n,s}}, K_{X_{n,s}}) \leq 0$.

Moreover, Theorem 0.6 was used in [15, Theorem 6.11] stating that a $(-1)$ Weyl line and $(-1)$ Weyl divisor part of a base locus of an general effective divisor $D$ don’t intersect. This allows one to create resolutions of singularities of an effective divisor $D$ on $X_{n,s}$, and to prove a Riemann Roch type statement [15, Corollary 6.18] for the Euler characteristics of the line bundle $O(D)$, where $D$ is the proper transform of $D$ under the blow up of $(-1)$ curves and linear base locus. In particular, the binomial formula $\chi(D)$ gives the expected dimension for the space of global section $h^0(O(D))$ for any effective divisor $D \in \text{Pic}(X_{n,s})$ counting contributions of $(-1)$ curves and linear spaces that are base locus of $D$.

Theorem 0.6 was also used in [15, Theorem 6.11] to prove that two $(-1)$ Weyl hyperplanes contained in the base locus of an effective divisor $D$ have to be orthogonal with respect with the Mukai pairing. This remark motivates the definition of Weyl cycles (see [6]) in $X_{n,s}$ as irreducible components of the intersection of $(-1)$ Weyl divisors on $\text{Pic}(X_{n,s})$, which are pairwise orthogonal with respect to the Dolgachev-Mukai pairing.

The birational geometry of Mori Dream Spaces is determined by Weyl cycles defined in [6], and the geometric computations of such varieties is in progress for $s \leq n + 3$ (ph.d thesis)[39]. For example, Weyl surfaces in $X_{4,8}$ were computed by two different methods in [14] and [6]. In Section 7, we will show an explicit example of computation of Weyl surface as intersection of two divisorial $(-1)$ classes. We will return to some of these topics in Section 7. Currently there is no general definition for arbitrary dimensional $(-1)$ classes of dimension at least 2 ie algebraic equations of type 3.1 that describe Weyl cycles.
Acknowledgements. The collaboration that resulted in this article was first started at two conferences: “Crossing Walls in Enumerative Geometry” held at Snowbird Center in Salt Lake City and “the Geometry and Physics of Quantum Curves” held at the BIRS center in Banff. The authors would like to thank the organizers for the inspiring conferences. In addition, the authors are also indebted to BYU and CMU for hosting them. Much of the work for this article was accomplished while visiting these two institutions. This collaboration was partially supported by Collaboration Grant 586691 from the Simons Foundation and National Science Foundation Grant DMS - 1802082.

1. On Cox Rings and $(-1)$ curves.

In this section we will discuss what is already known about Cox rings and $(-1)$ curves on rational surfaces. We will begin with Cox rings.

1.1. Cox Rings. The connection between Hilbert’s fourteenth problem and the blow up of $\mathbb{P}^n$ is realized via the Cox ring, that we will briefly summarize. We remind that the example of Nagata was generalized by Steinberg in [40] for $G = \mathbb{G}_a^6$, again by Mukai in [31] for $G = \mathbb{G}_a^3$ and blowing up $\mathbb{P}^2$ in nine points (or more generally for $\dim G = i \geq 3$ and blowing up $s \geq \frac{i^2}{2}$ points).

Recall that if $X$ a projective variety whose Picard group is freely generated by divisors $D_1, \ldots, D_r$, then the Cox ring is defined by

$$\text{Cox}(X) = \bigoplus_{(n_1, \ldots, n_r) \in \mathbb{Z}^r} H^0(X, n_1D_1 + \ldots + n_rD_r).$$

Notice $X$ is toric if and only if its Cox ring is polynomial. In [23], Hu and Keel proved that a projective variety $X$ is a Mori Dream Space if and only if $\text{Cox}(X)$ is finitely generated. For example, all del Pezzo surfaces (i.e. the blow up of a projective plane in $s$ points, for $s \leq 8$) are Mori Dream Spaces. In fact in [41] the Cox ring of del Pezzo surfaces is proved to be a quadratic algebra—that is the Cox ring is generated in degree 1 with all relations in degree 2. As further examples, it is known that $X_{3,7}$ and $X_{4,8}$ are Mori dream spaces, but the Cox ring is only known for $X_{3,7}$ (see [38]).

Returning to the discussion in Section 0.1, if we consider $G = \mathbb{G}_a^2$, then Castravet–Tevelev prove in [11] that $S^G$ is finitely generated, i.e. Cox ring of the blowup $X_{s-3,s}$ is a Mori dream space. In Nagata’s example, we see that $X_{2,16}$ is not a Mori Dream Space, and via Mukai, the same is true for $X_{5,9}$.

An important class of divisors on $X_{2,s}$ are known as $(-1)$ curves. Their importance is illustrated in the following results. In [4] Batyrev and Popov proved that the Cox rings for del Pezzo surfaces are generated by $(-1)$ curves for $s \leq 7$, and by $(-1)$ curves together with the anticanonical class for $s = 8$. Moreover, $\text{Cox}(X_{n,s})$ is generated by divisorial $(-1)$ classes for $s \leq n + 3$ [11]. In this paper we study such divisors and prove several results generalizing what is known about $(-1)$ curves (in dimension two) to higher dimension.

Finally, let us mention two more results related to the current work. In [31], Mukai extended the action of Nagata to products of projective spaces. Let $X_{a,b,c}$ denote the blown up product $\mathbb{P}^{e-1} \times \ldots \times \mathbb{P}^{e-1}$ of $a - 1$ terms, at $b + c$ general points. Then $\text{Cox}(X_{a,b,c})$ is finitely generated if and only if $\frac{1}{a} + \frac{1}{b} + \frac{1}{c} > 1$ (see [11], [32]).
In [42] Totaro, discusses Hilbert’s fourteenth problem over arbitrary fields, in particular over fields of positive characteristics. For some cases, he relates finite generation of the total coordinate ring, to finiteness of a Mordell–Weil group.

1.2. **$(-1)$ curves on rational surfaces.** The theory for $n = 2$ is particularly nice. In this section we recall main important results obtained for $X := \mathbb{P}^2$, the blown up projective plane in a collection of $s$ general points. The main results of the later sections are in large part inspired by what we know in dimension two, with some important differences, which we will try to point out. In this case a divisor is a planar curve.

We introduce the following intersection table on $\text{Pic}(X)$

\[ \cdot : \text{Pic} X \times \text{Pic} X \to \mathbb{Z} \]

defined by

\[ H \cdot H = 1, \]
\[ H \cdot E_i = 0, \]
\[ E_i \cdot E_j = -\delta_{i,j}. \]

We recall the following definition of $(-1)$ curves on $X$ (see also [36]).

**Definition 1.1.** A smooth divisor $D \in \text{Pic} X$ is a $(-1)$ curve if $D$ is irreducible, rational and has self-intersection $D \cdot D = -1$.

To illustrate the importance of $(-1)$ curves on $X$ we will first recall two important conjectures in the Interpolation Problems area.

The first of these is a conjecture by Gimigliano-Harbourne-Hirschowitz regarding effective divisors on $X$ (see e.g. [19, 20, 22]). Ciliberto and Miranda proved in [29] that this is also equivalent to a conjecture of Segre; nowadays this conjecture is known as SGHH conjecture.

Let $\chi(X, \mathcal{O}_X(D))$ denote the Euler characteristic of the sheaf $\mathcal{O}_X(D)$. This can be computed via Riemann-Roch theorem for divisors on the rational surface $X$.

\[ \chi(X, \mathcal{O}_X(D)) = 1 + \frac{D \cdot (D - K_X)}{2} - \dim H^1(X, \mathcal{O}_X(D)). \]

**Conjecture 1.2** (Gimigliano-Harbourne-Hirschowitz). Let $D \in \text{Pic}(X)$ an effective divisor of form (0.1). Then

\[ \chi(X, \mathcal{O}_X(D)) = \dim H^0(X, \mathcal{O}_X(D)) \]

if and only if $D \cdot C \geq -1$ for all $(-1)$ curves $C$ on $X$.

**Remark 1.3.** One can formulate Conjecture 1.2 for any general effective divisor $D$ as follows: Let $C$ be any $(-1)$ curve so that $k_C := -D \cdot C > 0$, then

\[ \dim H^0(X, \mathcal{O}_X(D)) = \chi(X, \mathcal{O}_X(D)) + \sum_{C \cdot D < 0} \left( \frac{k_C}{2} \right). \]

In order to state the second conjecture, consider a homogeneous divisor $D$, i.e. a divisor that has all multiplicities equal $m_1 = \ldots = m_s = m$. For degree and multiplicities large enough, whenever the ratio $\frac{d}{m} < \sqrt{s}$ is bounded, then $\chi(X, \mathcal{O}_X(D))$ is negative. By symmetry, if $s > 9$ then no $(-1)$ curve can intersect a homogeneous divisor $D$ negatively and by Conjecture 1.2 one expects that $\dim H^0(X, \mathcal{O}_X(D)) = 0$. This motivates the following conjecture.
Conjecture 1.4 (Nagata). If $\frac{d}{m} < \sqrt{s}$ then $D$ is not effective.

Nagata proved this conjecture when $s$ is a perfect square [36]. In fact, both Conjectures 1.2 and 1.4 are known to be true for homogeneous divisors whenever the number of points, $s$, is a perfect square [30]. Conjecture 1.4 also has a more general form for non-homogeneous divisors, but for simplicity we will not discuss it here.

These conjectures illustrate the importance of $(-1)$ curves on $X$, and we now describe what is known about $(-1)$ curves. In later sections, we will obtain similar results to those mentioned here but in higher dimension.

Let $W_{2,s}$ denote the Weyl group on $X_{2,s}$ generated by reflections (see Section 2.2 for more discussion of this group.) In 1960 Nagata introduces classes of *pre-exceptional type*, namely the orbit of the Weyl group $W_{2,s}$ action on one exceptional divisor (see Section 2.2 for a description of the Weyl group). He proves the fundamental result that they are in bijective correspondence with $(-1)$ curves as in the following theorem:

**Theorem 1.5 (Nagata, [36]).** There exists a bijection between the set of $(-1)$ curves on $X$ and the orbit of the Weyl group on one exceptional divisor, say $W_{2,s} \cdot E_i$. In particular the Weyl group acts transitively on the set of exceptional curves.

Theorem 1.5 of Nagata is based on the Lemma of Max Noether which is further exposited in [16] (and slightly reformulated in [13, Lemma 2.2]). We obtain a similar result for $n \geq 2$ (see Theorem 0.6 and the proof in Section 5).

**Theorem 1.6 (M. Noether’s inequality).** Let $D$ be the class of an irreducible rational curve satisfying $-2 \leq D \cdot D \leq 1$. Then there exist $i_1 < i_2 < i_3$ such that

$$m_{i_1} + m_{i_2} + m_{i_3} > d.$$
Remark 1.9. Any divisor $D$ on the blown up plane $X_{2,s}$, satisfying any two conditions of the set of four equivalent relations of Lemma 1.7 is effective. In particular $(−1)$ curves are effective. This follows from equality (4) since

$$\chi(X, \mathcal{O}_X(D)) = \dim H^0(X, \mathcal{O}_X(D)) - \dim H^1(X, \mathcal{O}_X(D)) = 1.$$  

Let us also mention that although effectivity of $(−1)$ curves is implied by the definition in dimension two, this is no longer the case in higher dimension. In Example 3.4 we see a divisor satisfying the numerical conditions required for being a divisorial $(−1)$ class, but the curve is not effective, so it won’t be in the Weyl group action $W_{n,s}E_i$. Therefore one needs to introduce effectivity in the definition of divisorial $(i)$ classes!

The following result, stronger than Remark 1.9, holds only in dimension two. It follows from by property (3) of Corollary 2.7 and property (4) of Lemma 1.7.

Corollary 1.10. If $D$ is a $(−1)$ curve then

$$\dim H^0(X, \mathcal{O}_X(D)) = 1 \quad \dim H^1(X, \mathcal{O}_X(D)) = 0.$$  

In particular Conjecture 1.2 holds for $D$.

In addition, Dolgachev obtains the following result, using the same techniques as Nagata.

Proposition 1.11 (Dolgachev [16]). There are no irreducible, rational curves on $X$ with $D \cdot D = -2$.

In [13] the authors prove that the irreducibility condition for $(−1)$ curves can be replaced by a numerical condition. More precisely, they prove the following:

Theorem 1.12 (Dumitrescu–Osserman, [13]). Let $X$ be the blow up of $\mathbb{P}^2$ at very general points $p_1, \ldots, p_s$. A divisor class $D$ is the class of a $(−1)$ curve if and only if either it is one of $E_i$ or it is of the form $dH - m_1E_1 - \ldots - m_sE_s$ with $d > 0, m_i \geq 0$ for all $i$ so that any two equivalent conditions of Lemma 1.7 hold and moreover for all $0 < d' < d$ and all $(−1)$ curves $C$ of degree $d'$ on $X$, we have $D \cdot C \geq 0$.

Example 1.13. Notice that the last condition is needed. Indeed, as observed by Dumitrescu–Osserman in [13], the divisor $D = 5H - 3E_1 - 3E_2 - E_3 - \ldots - E_{10}$ satisfies the numerical conditions in Equation (0.2), but fails the last condition of Theorem 1.12, with $C = H - E_1 - E_2$. We see that $C$ is a $(−1)$ curve, however $D \cdot C = -1$. Moreover, we see that $D$ is not irreducible as $D$ it splits as the sum of two curves $H - E_1 - E_2$ and $4H - 2E_1 - 2E_2 - E_3 - \ldots - E_{10}$. Therefore $D$ is not a $(−1)$ curve.

Example 1.14. Theorem 1.12 essentially says that if $D$ satisfies the numerical conditions of Theorem 1.7, then we can check irreducibility by intersecting with $(−1)$ curves of smaller degree. For general curves in the blow up $X_{2,s}$, irreducibility cannot be tested by intersection with $(−1)$ curves. The theorem only applies to divisors satisfying the conditions of Lemma 1.7. Indeed, take a sextic with nine double points $D = 6H - 2E_1 - \ldots - 2E_9$ and notice that this curve does not satisfy the requirements of $(−1)$ curve, since $D \cdot D \neq -1$, and it does not have arithmetic
genus \( p_a(D) \neq 0 \). Furthermore, \( D \) is not irreducible; it consists of the double cubic passing through the nine points. However, one can check that \( D \) does satisfy the numerical criterion \( D \cdot C \geq 0 \) for all \((-1)\) curves \( C \) of Theorem 1.13.

2. Weyl group action on \( \text{Pic}(X_{n,s}) \) and the Mukai pairing.

In this section we discuss the Weyl group action and an important class of strongly birational maps on \( \mathbb{P}^n \), called the standard Cremona transformations.

2.1. Weyl group action. The standard Cremona transformation based at the \( n+1 \) coordinate points of \( \mathbb{P}^n \) is defined to be the birational map

\[
[x_0, \ldots, x_n] \rightarrow \left[ \frac{1}{x_0}, \ldots, \frac{1}{x_{n+1}} \right].
\]

This map is given by divisors of degree \( n \) with multiplicity \( n-1 \) at each of the \( n+1 \) coordinate points. The standard Cremona transformation contracts each of the coordinate hyperplanes to a point. The indeterminacy locus of the standard Cremona transformation consists in the collection of \( n+1 \) coordinate points, and all linear subspaces of dimension at most \( n-2 \) generated by these points, therefore it is a strong birational map, i.e. an isomorphism in codimension 1.

Moreover it induces an automorphism of the Picard group of \( X_{n,s} \) for \( s \geq n+1 \) points and by abuse of notation we will denote \( \text{Cr} : \text{Pic}X_{n,s} \rightarrow \text{Pic}X_{n,s} \) via the rule

\[
\text{Cr}(dH - \sum_{i=1}^{s} m_i E_i) = (d-k)H - \sum_{i=1}^{n+1} (m_i-k)E_i - \sum_{i=n+2}^{s} m_i E_i
\]

where

\[
k = m_1 + \cdots + m_{n+1} - (n-1)d
\]

and the first \( n+1 \) points are chosen to be the coordinate points of \( \mathbb{P}^n \).

Denote the canonical divisor on \( X_{n,s} \) by

\[
K_{X_{n,s}} := -(n+1)H + (n-1)E_1 + \cdots + (n-1)E_s.
\]

Remark 2.1. The standard Cremona transformation of \( \mathbb{P}^n \) (1) is an involution of \( \mathbb{P}^n \), that (2) fixes canonical divisor of \( X_{n,s} \), and (3) preserves semigroup of effective divisors. Moreover, (4) Cremona transformation preserves dimension of space of global sections of divisors (see [17]). These four points are summed up in the following equations.

1. \( \text{Cr} \text{Cr} D = D \)
2. \( \text{Cr} K_{X_{n,s}} = K_{X_{n,s}} \)
3. If \( D \geq 0 \) then \( \text{Cr} D \geq 0 \).
4. \( \dim H^0(X_{n,s}, \mathcal{O}(D)) = \dim H^0(X_{n,s}, \mathcal{O}(\text{Cr} D)) \).

Remark 2.2. By property (4) of Remark 2.1, if \( D \) is an effective divisor then \( \text{Cr}(D) \) is also effective so it has positive degree. Indeed, one can also check that

\[
\deg \text{Cr}(D) = nd - \sum_{i=1}^{n+1} m_i > 0
\]
since \( D \) is effective. However, the multiplicities of \( \text{Cr}(D) \) may not all be positive. Indeed,

\[
m_{n+1} - k = (n - 1)d - \sum_{i=1}^{n} m_i
\]

can be negative if \( D \) is not irreducible—for example, if the hyperplane through first \( n \) points is a fixed component of \( D \).

**Remark 2.3.** In [16] Dolgachev defines a Cremona isometry to be an automorphism of \( A^1(X) \) preserving Dolgachev-Mukai intersection pairing (defined in Equation (2.4), see also Theorem 2.10) and Properties (2) and (3) of Remark 2.1. He further proves that the group of effective Cremona isometries—the ones induced by automorphisms of \( X \)—is the Weyl group. This property is far from being true if \( \dim X \geq 3 \).

We can generalize the map \( \text{Cr} \) to include any subset \( I \subset \{1, 2, \ldots, s\} \) of size \( n+1 \) by precomposing \( \text{Cr} \) with a projective transformation, taking the points indexed by \( I \) to the \( n+1 \) coordinate points of \( \mathbb{P}^n \). This transformation is also called a *standard Cremona transformation*, and we denote it by \( \text{Cr}_I \). In other words, a standard Cremona transformation is a transformation projectively equivalent to \( \text{Cr} \). Obviously, the properties of Remark 2.1 also hold for \( \text{Cr}_I \).

For later section it is useful to mention the following result that holds only for blown up planes.

**Theorem 2.4.** For any divisor \( D \) on \( X = X_{2,s} \) we have the following

\[
\dim H^0(X, \mathcal{O}(\text{Cr}D)) = \dim H^0(X, \mathcal{O}(D))
\]

\[
\dim H^1(X, \mathcal{O}(\text{Cr}D)) = \dim H^1(X, \mathcal{O}(D)).
\]

**Proof.** To prove this result apply adjunction formula in dimension 2:

\[
\chi(X, \mathcal{O}_X(\text{Cr}D)) = 1 + \frac{\text{Cr}D \cdot (\text{Cr}D - K_X)}{2} = \chi(X, \mathcal{O}_X(D)).
\]

Indeed we will see in Theorem 2.10 that \( \text{Cr} \) preserves the intersection pairing (or the Dolgachev-Mukai pairing in higher dimension). Conclude with Properties (2) and (4) of Remark 2.1. \( \square \)

### 2.2. Root systems and Weyl groups.

The exposition of this section follows Dolgachev [16] and Mukai [31], [32]. In [27], Manin associated the group \( E_6 = T_{3,2,2} \) to the configuration of 27 lines on a nonsingular cubic surface in \( \mathbb{P}^3 \)—i.e. the blow up of \( \mathbb{P}^2 \) at six points. This result was generalized by Dolgachev for \( X_{n,s} \) as we describe below. For \( s \geq n + 1 \) let \( L \) be a lattice of rank \( s + 1 \) with orthogonal basis \( H, E_1, \ldots, E_s \). The orthogonal complement of the canonical divisor \( K_{X_{n,s}} \) (see Equation (2.2)) has basis \( \mathcal{B} \) given by

\[
\alpha_1 := E_1 - E_2, \quad \alpha_2 := E_2 - E_3, \quad \ldots \quad \alpha_{s-1} := E_{s-1} - E_s, \quad \text{and}
\]

\[
\alpha_s := H - \sum_{i=1}^{n+1} E_{i}
\]

that becomes a root system for the vector space \( V = \text{Pic}(X_{n,s}) \otimes \mathbb{R} \). The dual base is \( \mathcal{B}^\vee = \{\alpha_1^\vee, \ldots, \alpha_s^\vee\} \) in \( N_1(X_{n,s}) \), where \( \alpha_i^\vee = f_i - f_{i+1} \) for \( i \leq s - 1 \) and
\( \alpha^\vee_s = (n - 1)l - \sum_{i=1}^{n+1} f_i \). Here, \( f_i \) denotes the class of a line in the exceptional divisor \( E_i \) and \( l \) a general line class on \( X_{n,s} \), so \( f_i \cdot E_i = -1 \) and \( l \cdot H = 1 \). Let \( T_i : V \to V \) be the simple reflections for \( 1 \leq i \leq s \) defined by

\[
T_i(x) := x + \alpha^\vee_i(x) \cdot \alpha_i.
\]

For any \( i < s \), we see that \( T_i(E_i) = E_{i+1} \) and \( T_i(E_{i+1}) = E_i \) and \( T_i \) leaves the other bases elements of \( \text{Pic}(X_{n,s}) \) fixed, while

\[
T_s(H) = nH - (n - 1)\sum_{i=1}^{n+1} E_i
\]

\[
T_s(E_j) = H - \sum_{i \neq j, i=1}^{n+1} E_i \quad \text{for } j \leq n + 1
\]

\[
T_s(E_j) = E_j \quad \text{for } j > n + 1
\]

From this description, we can recognize \( T_s \) as the automorphism induced by \( \text{Cr} \) on \( \text{Pic}(X_{n,s}) \) as described in (2.1). The Dynkin diagram of the group generated by the \( T_i \) for \( 1 \leq i \leq s \) is often described as \( T_{n+1,s-n-1,2} \), which denotes a T-shaped graph with three legs of length 2, \( n+1 \) and \( s-n-1 \), resp.

\[
\begin{array}{cccccc}
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
n + 1 & s - n - 1 \\
\end{array}
\]

\textbf{Figure 1}. Dynkin diagram for \( T_{n+1,s-n-1,2} \)

The construction of Dolgachev was generalized by Mukai in [32] for products of projective spaces \( X_{a,b,c} \) whose corresponding root systems are comprised of \( a + b + c - 2 \) vertices representing a basis for the vector space \( \text{Pic}(X_{a,b,c}) \otimes \mathbb{Z} \mathbb{R} \). The Dynkin diagram in this case is \( T_{a,b,c} \), which has the shape of a “T” and with the three legs having length \( a, b \) and \( c \), resp.

\textbf{Definition 2.5}. The \textit{Weyl group} \( W_{n,s} \) is defined to be the group generated by all simple reflections \( T_i \) on \( X_{n,s} \) where \( 1 \leq i \leq s \).

\textbf{Remark 2.6}. Any element of the Weyl group \( w \in W_{n,s} \) is a composition of standard Cremona transformations based at arbitrary subsets of \( n + 1 \) points of \( \{1, \ldots, s\} \). In other words, there exist index subsets \( I_1, \ldots, I_t \), where \( I_j \subset \{1, \ldots, s\} \) and \( |I_j| = n + 1 \), so that

\[
w = \text{Cr}_{I_1} \circ \text{Cr}_{I_2} \circ \ldots \circ \text{Cr}_{I_t}.
\]

Obviously the inverse of \( w \) in the Weyl group \( W_{n,s} \) is

\[
w^{-1} = \text{Cr}_{I_t} \circ \text{Cr}_{I_{t-1}} \circ \ldots \circ \text{Cr}_{I_1}.
\]

\textbf{Corollary 2.7}. Properties (2), (3) and (4) of Remark 2.1 hold for any Weyl group element \( w \in W_{n,s} \).

The group of \textit{birational automorphisms} of a projective space \( \mathbb{P}^n \) is called Cremona group (see e.g. [16]).

Recall the following explicit result holds only in the two dimensional case:
Theorem 2.8 (M. Noether–Castelnuovo). The complex Cremona group of $\mathbb{P}^2$ is generated by standard Cremona transformations.

This is no longer true for $\mathbb{P}^n$, when $n \geq 3$. In fact describing the structure of the Cremona group is a difficult problem.

2.3. Properties of the Dolgachev-Mukai pairing. We introduce a pairing on Picard group $\text{Pic}(X_{n,s})$ following [32] (recall the description of $\text{Pic}(X_{n,s})$ in (0.1)):

$$(\cdot, \cdot) : \text{Pic}(X_{n,s}) \times \text{Pic}(X_{n,s}) \to \mathbb{Z}.$$ 

The pairing has a simple description:

$$(H, H) = n - 1,$$

$$(H, E_i) = 0,$$

$$(E_i, E_j) = -\delta_{i,j}. \quad (2.4)$$

By Bezout theorem for $n = 2$, the Dolgachev-Mukai pairing $(C, F) = C \cdot F$ coincides with the intersection of two general divisors (curves) $C$ and $D$ on $X$.

Definition 2.9. For a divisor $D = d_1H - \sum_{i=1}^{s} m_iE_i \in \text{Pic}(X_{n,s})$ denote by $\tilde{D} := d_1H - d_1E_0 - \sum_{i=1}^{s} m_iE_i \in \text{Pic}(X_{n+1,s+1})$ to be the cone over $D$ with vertex at the exceptional divisor denoted by $E_0$. This cone consists by the union of all lines through $E_0$ and points of $D$. Part (1) of next Theorem was also observed by Laface and Ugaglia in [25].

Theorem 2.10. The following two statements hold:

1. The Cremona transformation on $X_{n,s}$ preserves the Dolgachev-Mukai pairing and the anticanonical degree of divisors.
2. Cones in $X_{n+1,s+1}$ over divisors in $X_{n,s}$ with the same vertex set preserve the intersection pairing Dolgachev-Mukai and the anticanonical degree of divisors.

Proof. For (1), let $D := d_1H - \sum_{i=1}^{s} m_iE_i$ and $F = d_2H - \sum_{j=1}^{s} p_jE_j$ be divisors on $X_{n,s}$ with $m_i, p_i \geq 0$. From our description of the Cremona action (2.1) we see

$$\text{Cr } D := (d_1 - k_1)H - \sum_{i=1}^{n+1}(m_i - k_1)E_i - \sum_{j=n+2}^{s} m_jE_j$$

$$\text{Cr } F := (d_2 - k_2)H - \sum_{i=1}^{n+1}(p_i - k_2)E_i - \sum_{j=n+2}^{s} p_jE_j$$
where $k_1 := m_1 + \ldots + m_{n+1} - (n - 1)d_1$ and $k_2 := p_1 + \ldots + p_{n+1} - (n - 1)d_2$. Then

$$\langle \text{Cr} D, \text{Cr} F \rangle = (n - 1)(d_1 - k_1)(d_2 - k_2) - \sum_{i=1}^{n+1} (m_i - k_1)(p_1 - k_2) - \sum_{j=n+2}^{s} m_j p_j$$

$$= (D, F) - k_1[k_2 + (n - 1)d_2 - \sum_{j=1}^{n+1} p_j] - k_2[k_1 + (n - 1)d_1 - \sum_{i=1}^{n+1} m_i]$$

$$= (D, F).$$

By Property (2) of Remark 2.1, the canonical divisor $-K_{X_{n,s}}$ is invariant under the Cremona action. (See Equations (2.2) and (2.1) for descriptions of the canonical divisor and Cr, resp.)

$$\text{Cr} K_{X_{n,s}} = K_{X_{n,s}}.$$

We conclude

$$\text{adeg}(D) := \frac{\langle D, -K_{X_{n,s}} \rangle}{n - 1}$$

$$= \frac{\langle \text{Cr} D, -\text{Cr} K_{X_{n,s}} \rangle}{n - 1}$$

$$= \frac{\langle \text{Cr} D, -K_{X_{n,s}} \rangle}{n - 1}$$

$$= \text{adeg}(\text{Cr}(D)).$$

To prove (2), take $\tilde{D} := d_1 H - d_1 E_0 - \sum_{i=1}^{s} m_i E_i$ and $\tilde{F} = d_2 H - d_2 E_0 - \sum_{j=1}^{s} n_j E_j$ cones in $X_{n+1,s+1}$ over divisors $D$ and $F$.

$$\langle \tilde{D}, F \rangle = nd_1 d_2 - \sum_{i=1}^{s} m_i n_i$$

$$= (n - 1)d_1 d_2 - \sum_{i=1}^{s} m_i n_i$$

$$= (D, F)$$

$$\text{adeg} \tilde{D} = (n + 2)d_1 - \sum_{i=1}^{s} m_i$$

$$= (n + 1)d_1 - \sum_{i=1}^{s} m_i$$

$$= \text{adeg}(D).$$

\[\square\]

3. Divisorial $(i)$ classes on blown up projective space.

In this section we define divisorial $(i)$ classes we will be studying, and prove some preliminary results. We also give examples of what we call sporadic divisors.

We are now prepared to make the following definition (see (0.2) in the Introduction).
**Definition 3.1.** Let $i \in \{-1, 0, 1\}$ and $D \in \text{Pic} \ X_{n,s}$ be a smooth divisor

(1) We say $D$ is a *divisorial (i) class* on $X_{n,s}$ if $D$ is an effective and irreducible divisor that satisfies the following two conditions:

(a) $\langle D, D \rangle = i$,

(b) $\deg(D) = \frac{1}{n}. \langle D, -K_{X_{n,s}} \rangle = 2 + i$.

(2) We say $D$ is a $(i)$ *Weyl divisor* if there exists $w \in W_{n,s}$ such that $D = w(H_{n-1-i})$, where $H_{n-1-i}$ is a hyperplane passing through $n-1-i$ points.

**Remark 3.2.** In [25, Definition 4.1], Laface and Uraglia define $(-1)$ *classes* to be divisors $D$ that are effective, *reduced* and irreducible satisfying Equations (0.2). This is equivalent to Definition 3.1, when $i = -1$. However, Lemma 3.3 proves that the reducibility assumption—which does not appear in this definition—is redundant. In [38] Park and Lesieutre briefly relate $(-1)$ divisors to effective divisors satisfying conditions (0.2).

**Lemma 3.3.** Let $i \in \{-1, 0, 1\}$ and $D \in \text{Pic} \ X_{n,s}$ be an irreducible divisor satisfying $\langle D, D \rangle = i$ and $\deg D = 2 + i$. Then $D$ is reduced.

**Proof.** Assume $D$ is a non reduced irreducible divisor satisfying $\langle D, D \rangle = i$. Assume, for some positive integer $m > 1$, we have

$$D = mF.$$ 

We obtain

$$\langle D, D \rangle = \langle mF, mF \rangle = m^2. \langle F, F \rangle = i.$$

For $i \in \{-1, 1\}$ we obtain a contradiction, since $\langle D, D \rangle$ is an integer and $m > 1$.

Assume now $i = 0$, then $\langle D, D \rangle = 0$ implies $\langle F, F \rangle = 0$. Now $\deg D = 2$ implies that $m \cdot \deg F = 2$; but the condition $m > 1$ implies $m = 2$, i.e. $\deg F = 1$. A divisor with these numerical properties can not exist, by Corollary 5.4. We obtain a contradiction. 

The next example shows that unlike the case of $\mathbb{P}^2$ (see Remark 1.9), the numerical conditions of Definition 3.1 are not enough to guarantee effectivity. (Also see Definition 1.1.) This shows why the effectivity hypothesis is needed in the definition.

**Example 3.4.** Take $i \in \{-1, 0, 1\}$ and $D := 10H - 7E_1 - 6E_2 - 6E_3 - 6E_4 - 6E_5 - E_6 - \ldots - E_{12-i}$ in $\text{Pic}(X_{3,12-i})$. Then $D$ satisfies numerical conditions of a divisorial (i) class since

$$\langle D, D \rangle = (3 - 1) \cdot 10^2 - 7^2 - 4 \cdot 6^2 - (7 - i) = i$$

$$\deg D = \frac{\langle D, -K_{X_{n,s}} \rangle}{2} = 4 \cdot 10 - (38 - i) = 2 + i$$

Note that in $\text{Pic}(X_{n,s})$ any effective divisor satisfies condition $nd \geq \sum_{j=1}^{n+2} m_j$ for any index set of size $n + 2$ of $\{1, \ldots, s\}$ while $d \geq m_j$ for any $1 \leq j \leq s$. We see that $D$ is not effective, since $3 \cdot 10 < 7 + 6 + 6 + 6$ (even though $d \geq m_j$).

We also emphasize that Lemma 1.7 doesn’t hold on $X_{n,s}$. Notice that the numerical conditions of Definition 3.1 are conditions (1) and (3) of Lemma 1.7. We now present an example of a divisor satisfying numerical conditions of Definition 3.1 (in
fact we will see by Theorem 0.6 that $D$ is a divisorial $(-1)$ class) that does not satisfy $\chi(X, \mathcal{O}_X(D)) = 1$ (condition 4 of Lemma 1.7). Moreover, standard Cremona transformations do not preserve higher cohomology groups, and therefore also do not preserve the Euler characteristics of divisors (as in Theorem 2.4).

**Example 3.5.** Consider the following divisor in $X = X_{4,7}$ in the exception list of the celebrated Alexander–Hirschowitz Theorem

$$D := 3H - 2E_1 - \ldots - 2E_7.$$ 

It is easy to see that $D$ satisfies numerical conditions (0.2). In fact, $D$ is in the Weyl group orbit of an exceptional divisor $W_{4,7} \cdot E_3$, therefore by Theorem 0.6, it is effective and irreducible so $D$ is a divisorial $(-1)$ class. To see this consider the following sets of indices: $I_1 = \{1, 2, 3, 4, 5\}$, $I_2 = \{1, 2, 3, 6, 7\}$ and $I_3 = \{3, 4, 5, 6, 7\}$. One can check that $D = Cr_{I_1} Cr_{I_2} Cr_{I_3} E_3$. Moreover, from Property 4 of Remark 2.1 we see that $\dim H^0(X, \mathcal{O}_X(D)) = 1$.

Notice that

$$\chi(X, \mathcal{O}_X(D)) = \binom{7}{4} - 7 \binom{5}{4} = 0$$

implying that

$$\dim H^1(X, \mathcal{O}_X(D)) = 0.$$

We conclude that Theorem 2.4 also holds only in the planar case.

Finally, let us make one remark about rationality—the last remaining of the four conditions in Lemma 1.7. In the planar case the rationality of $(-1)$ curves follows from the Adjunction formula as explained in Lemma 1.7. However, in higher dimension a numerical criterium for rationality is difficult to find. For example, it was proved by Castelnuovo that any complex surface with the property that both the irregularity and second plurigenus vanish is rational. This criterium is used in the Enriques—Kodaira classification to identify the rational surfaces. In this paper we will not address the rationality question of divisorial $(i)$ classes.

The notion of $(-1)$ *divisors* has been defined previously by Mukai. Our definition is more restrictive when $i = -1$. In order to state Mukai’s definition, recall a strong birational map (or pseudo-isomorphism) is an isomorphism outside a set of codimension at least two.

**Definition 3.6** (Mukai, [32]). A $(-1)$ *divisor* on $X_{n,s}$ is a divisor $D$ of $X_{n,s}$ for which there exists a strong birational map from $X_{n,s}$ to some $X'$ so that the image of $D$ can be contracted to a smooth point.

**Remark 3.7.** Since the standard Cremona transformation is a strong birational map, any element of the orbit of the Weyl group action on an exceptional divisor $W_{n,s} \cdot E_i$, is a $(-1)$ divisor.

Even if the next remark is obvious (see also Remark 1.9) we will include it here just to emphasize that both definitions of $(-1)$ divisors introduced by Mukai and divisorial $(-1)$ classes are generalizing the notion of $(-1)$ curves in the plane.

**Remark 3.8.** On the blow up of the projective plane in points the three definitions *divisorial* $(-1)$ *classes* (Definition 3.1), $(-1)$ *divisors* (Definition 3.6) and $(-1)$ *curves* (Definition 1.1) are equivalent.
Proposition 3.9. For \( i \in \{-1, 0, 1\} \), let \( D \) be a divisorial \((i)\) class on \( X_{n,s} \). Then

1. \( w(D) \) is also a divisorial \((i)\) class for any Weyl group element \( w \in W_{n,s} \).
2. Cones over \( D \) are divisorial \((i)\) classes on \( X_{n+1,s+1} \).

Part (1) of this Proposition was also appeared in [25], but only when \( i = -1 \).

Proof. For (1) it is enough to prove that \( \text{Cr}(D) \) is a divisorial \((i)\) class by Remark 2.6.

Let \( D \) be a divisorial \((i)\) class. We have seen in Theorem 2.10

\[ \langle \text{Cr}(D), \text{Cr}(D) \rangle = \langle D, D \rangle = i \]

\[ \text{adeg(Cr}(D) = \text{adeg}(D) = 2 + i. \]

Property (3) of Remark 2.1 implies that \( \text{Cr}(D) \) is effective. The last thing we need to check is that \( \text{Cr}(D) \) is irreducible. Assume by contradiction that \( \text{Cr}(D) \) is not irreducible. For \( F, G \in \text{Pic}(X_{n,s}) \) then

\[ \text{Cr}(D) = F + G. \]

By Property (1) of Remark 2.1 we have

\[ D = \text{Cr}(F) + \text{Cr}(G). \]

This a contradiction of the irreducibility of \( D \). Thus \( \text{Cr}(D) \) is irreducible, and therefore a divisorial \((i)\) class.

We use the same technique to prove (2). Let \( \tilde{D} \) be the cone over \( D \). Indeed by Theorem 2.10,

\[ \langle \tilde{D}, \tilde{D} \rangle = \langle D, D \rangle = i \]

\[ \text{adeg}(\tilde{D}) = \text{adeg}(D) = 2 + i. \]

Obviously, \( \tilde{D} \) is effective because \( D \) is effective. Moreover, assuming that the cone \( \tilde{D} \) is not irreducible, \( \tilde{D} = \tilde{G} + \tilde{K} \) then denote by \( G \) and \( K \) to be the image of \( \tilde{G} \) and \( \tilde{K} \) under projection from the vertex. Then \( D = G + K \) contradicting the irreducibility assumption of \( D \). Thus the cone \( \tilde{D} \) is a divisorial \((i)\) class. \( \square \)

In particular, we see that divisorial \((-1)\) classes are also \((-1)\) divisors in the sense of Mukai’s definition (see Remark 3.7).

We end this section with several examples of important divisors that are not divisorial \((-1)\) classes. It is unknown if they are \((-1)\) divisors in the sense of Mukai, however we expect the first two examples (in Example 3.10) to be generators for the Cox rings of \( X_{3,9} \) and \( X_{4,14} \), resp. In fact, \( D_2 \) is related to the Keel–Vermeire divisor on \( \overline{M}_{0,6} \), which is known to be a generator of the Cox ring. We call them sporadic divisors. The other two examples in Remark 3.11 illustrate a point about divisors with base locus.

Example 3.10 (Sporadic divisors). Let \( D_1 \in \text{Pic}(X_{3,9}) \) and \( D_2 \in \text{Pic}(X_{4,14}) \) be defined by

\[ D_1 := 2H - E_1 - \ldots - E_9, \text{ and } D_2 := 2H - E_1 - \ldots - E_{14} \]

We can easily see that

\[ \text{adeg } D_1 = \frac{1}{2} \langle D_1, -K_{X_{3,9}} \rangle = 4 \cdot 2 - 9 = -1 \]

\[ \langle D_1, D_1 \rangle = -1 \]

\[ \langle D_2, D_2 \rangle = 4 \cdot 2 - 9 = -1 \]

\[ \langle D_1, D_2 \rangle = -1 \]
and
\[ \text{adeq } D_2 = \frac{1}{3} \langle D_2, -K_{X,4,14} \rangle = 5 \cdot 2 - 14 = -4 \]
\[ \langle D_2, D_2 \rangle = -2 \]
so neither \( D_1 \) nor \( D_2 \) is a divisorial \((-1)\) class.

However,
\[ \chi(X_{3,9}, \mathcal{O}_{X,3}(D_1)) = \begin{pmatrix} 5 \\ 2 \end{pmatrix} - 9 = 1. \]

and
\[ \chi(X_{4,14}, \mathcal{O}_{X,4,14}(D_2)) = \begin{pmatrix} 6 \\ 2 \end{pmatrix} - 14 = 1. \]

Although not divisorial \((-1)\) classes, we see that \( D_1 \) still satisfies two properties of Lemma (1.7), namely
\[ \langle D_1, D_1 \rangle = -1 \quad \text{and} \quad \chi(X_{3,9}, \mathcal{O}_{X,3,9}(D_1)) = 1 \]
while \( D_2 \) satisfies just one property of Lemma 1.7.

The importance of these divisors lies in the fact that both \( D_1 \) and \( D_2 \) are not in the Weyl group orbit of an exceptional divisor \( E_i \), but whenever they are contained in the base locus of any divisor \( D \), they will create a change in \( \dim H^0(X_{n,s}, \mathcal{O}_{X,n,s}(D)) \) in the sense of Conjecture 1.2 and its corollary.

We would like to investigate in future work if there are other numerical criterium to classify such sporadic divisors on \( X_{n,s} \).

**Remark 3.11.** The Alexander–Hirschowitz Theorem classifies all effective divisors \( D \) with double points in \( X_{n,s} \) for which
\[ \dim H^0(X_{n,s}, \mathcal{O}_{X,n,s}(D)) = \chi(X_{n,s}, \mathcal{O}_{X,n,s}(d)). \]
This theorem can also be stated in terms of the secant variety, namely the higher secant variety \( \sigma_s(V_{n,d}) \) to the Veronese embedding \( V_{n,d} \) of degree \( d \) in \( \mathbb{P}^n \) is non-defective with a short list of exceptions. Two of the exceptions are the two divisors \( F_1 \in \text{Pic}(X_{3,9}) \) and \( F_2 \in \text{Pic}(X_{4,14}) \) given by
\[ F_1 := 4H - 2E_1 - \ldots - 2E_9, \quad \text{and} \quad F_2 := 4H - 2E_1 - \ldots - 2E_{14} \]

Notice that divisors \( F_1 \) and \( F_2 \) have the quartics \( D_1 \) and \( D_2 \) respectively as base locus. Similar to the base locus Lemma 6.1 the Dolgachev-Mukai pairing between \( D_j \) and \( F_j \) is negative
\[ \langle F_1, D_1 \rangle = -2 \quad \text{and} \quad \langle F_2, D_2 \rangle = -2. \]

For both divisors \( F_j \) we have \( \chi(X_j, \mathcal{O}_{X_j}(F_j)) = 0 \), but they are effective since \( F_j = 2 \cdot D_j \). Therefore
\[ \dim H^0(X_j, \mathcal{O}_{X_j}(F_j)) = \dim H^1(X_j, \mathcal{O}_{X_j}(F_j)) = 1. \]

For arbitrary number of points in higher dimensional projective spaces, no analogue of Conjecture 1.2 exists for \( X_{n,s} \), except in the case \( s \leq n + 3 \); we state this conjecture as Conjecture 7.6.

In general, it is expected that all effective divisors \( D \) with \( \dim H^1(X_{n,s}, \mathcal{O}_{X,n,s}(D)) \neq 0 \) contain base locus. A variety that produces non-vanishing cohomology in degree 1 when contained as the fixed point of a divisor with multiplicity, is called a *special effect variety*. For example, the
two divisors $D_1$ and $D_2$ of our previous example are special effect varieties. Laface-Ugaglia conjectured in [26] that the only special effect divisors of $X_{3,s}$ are divisorial ($-1$) classes and divisors in the Weyl group orbit of $D_1$. It will be interesting to study if sporadic divisors (like $D_j$ or cones over $D_j$) have special numerical interpretation similar to divisorial ($-1$) classes.

4. A generalization of the Max Noether inequality to $\mathbb{P}^n$.

In previous sections we emphasized several differences between ($-1$) curves and divisorial $(i)$ classes. In this section we will prove Theorem 0.5, which we restate here. Recall the classes $\alpha_k$ from Section 2.2.

**Theorem (=Theorem 0.5).** Let $D$ be a divisor with $d \geq m_i \geq 0$ so that $\text{adeg} D = c + 2$ and $\langle D, D \rangle = c + e$ for two integers $c$ and $e$ satisfying $-2 \leq c, e \leq 1$. If $d = 1$ further assume that $\langle D, D \rangle < 0$. Then $\langle D, \alpha_k \rangle \geq 0$ for any $1 \leq k \leq s - 1$ and $\langle D, \alpha_s \rangle < 0$ after a suitable reordering of the indices.

Condition $\langle D, \alpha_k \rangle \geq 0$ says that we can rearrange the points so that $m_1 \geq \ldots \geq m_s$ and condition $\langle D, \alpha_s \rangle < 0$ says that $D$ is not Cremona reduced ie $m_1 + m_2 + \ldots + m_{n+1} > (n - 1)d$.

In the case $n = 2$, the original hypotheses of the Max Noether inequality—irreducibility, rationality and bounded self-intersection—apply to $(i)$ curves. In contrast, this new result (Theorem 0.5) says that under good numerical hypotheses of degree and self-intersection (notice the absence of the irreducibility assumption in the hypothesis), one can perform a Cremona transformation in such a way that reduces the degrees and multiplicities.

The next example shows that condition $d \geq m_j$ is mandatory in the hypothesis of Theorem 0.5.

**Example 4.1.** Take $D := 5H - 6E_1 - 2E_2 - E_3 - \ldots - E_{13} \in \text{Pic}(X_{3,13})$. Then

$$\langle D, D \rangle = (3 - 1) \cdot 5^2 - 6^2 - 2^2 - 11 = -1$$

$$(4.1) \quad \text{adeg} D = \frac{\langle D, -K_{X_{3,13}} \rangle}{2} = 4 \cdot 5 - (6 + 2 + 11) = 1$$

We can see that $c = -1$ and $e = 0$, however the maximal sum of four multiplicities is 10, and $(n - 1)d = 10$, so the conclusion of Theorem 0.5 does not hold. The point is $D$ is not effective, and moreover $m_1 > d$, so the theorem doesn’t apply to this divisor.

**Remark 4.2.** The proof of Theorem 0.5 can extend also to some cases where $e = 2$, but we will leave this to the interested reader.

**Remark 4.3.** Notice that the irreducibility condition in the hypothesis of the Noether’s original is replaced in Theorem 1.6 by the condition $d \geq m_j \geq 0$. This stronger version of the theorem was originally observed for the planar case in Theorem 1.12 of [13], however by Remark 1.9 the assumption $d \geq m_j$ can be eliminated only for $n = 2$.

**Remark 4.4.** Theorem 0.5 for $n = 2$ is a generalization of M. Noether inequality in $\mathbb{P}^2$. Indeed, notice the hypothesis of Theorem 1.6 requires the curve $D$ to be rational, and by the arithmetic genus formula this is equivalent to $\text{adeg}(D) = D \cdot (-K_X) = c + 2 \in \{0, 1, 2, 3\}$, while $D \cdot D = c \in \{0, 1, 2, 3\}$. On the other hand, the assumption of Theorem 0.5 for $n = 2$ implies that $p_a(D) = \frac{c}{2}$ and for effective
discussed in Remark 0.5 generalizes the planar Noether inequality to non-rational divisors $D$.

We will now dedicate the remaining part of this section to the proof of Theorem 0.5 generalizing Max Noether inequality from $\mathbb{P}^2$ to $\mathbb{P}^n$.

**Proof of Theorem 0.5.** Case 1. $s \leq n$. Condition $\text{adeg} D = 2 + c$ implies that $m_1 + \ldots + m_s - (n - 1)d = -c + 2(d - 1) \geq 1$ for $d \geq 2$. If $d = 1$, the hypothesis $\langle D, D \rangle < 0$ implies $s \geq n$ therefore the statement holds.

Case 2. $s > n + 1$. We order multiplicities in decreasing order of $m_1 \geq m_2 \geq \ldots \geq m_s$. We consider $d = m_1$ as a first case—i.e. $D$ is a cone—and prove the statement by induction on the dimension $n$.

The base case is $n = 2$. Let $t$ denote the last index with $m_t \neq 0$, i.e. $m_1, \ldots, m_t \neq 0$, but $m_{t+1} = \ldots = m_s = 0$. The conditions $\text{adeg} D = c + 2$ and $\langle D, D \rangle = c + e$ imply $-m_t^2 - \ldots - m_s^2 \geq -4$ and $2m_t - m_2 - \ldots - m_s \in \{0, \ldots, 3\}$. This forces $m_2 \leq 2, t \leq 5$ and $d \leq 3$. We conclude that the only possible cones for $n = 2$ satisfying hypothesis conditions are

- $d = 1$ and $2 \leq t \leq 3$;
- $d = m_1 = m_2 = 2$ and $t = 2$;
- $d = m_1 = 2, m_2 = 1$ and $2 \leq t \leq 5$;
- $d = m_1 = 3, m_2 = 1$ and $2 \leq t \leq 5$.

In each of the four cases above the conclusion holds. For $n \geq 3$, let $D = \tilde{F}$ be a cone over a divisor $F \in \text{Pic}(X_{n-1,s-1})$ of degree $d$ and multiplicities and $m_2, \ldots, m_s$. Theorem 2.10 implies that $F$ satisfies hypothesis

$$\langle \tilde{F}, \tilde{F} \rangle = \langle F, F \rangle = c + e \quad \text{and} \quad \text{adeg} \tilde{F} = \text{adeg} F = c + 2,$$

so by the induction hypothesis $m_2 + m_3 + \ldots + m_{n+1} > (n - 2)d$. Therefore $m_1 + m_2 + \ldots + m_{n+1} > (n - 1)d$. If $d = 1$ then condition $\langle D, D \rangle < 0$ implies that $m_k = 1$ for all $k \leq n$ therefore conclusion holds. We can therefore assume $d \geq 2, n \geq 2$ and $d > m_k$ for all $k$.

For $1 \leq j \leq n + 1$ define

$$q_j := \frac{\sum_{k=j}^s m_k^2}{\sum_{k=j}^s m_k}.$$

Because $m_j \geq m_k$ for $k \geq j$ we have that $m_j \geq q_j$ for any $1 \leq j \leq n + 1$. Set

$$r_j := m_j - q_j \geq 0.$$

and observe the following equalities

$$q_1 = \frac{(n - 1)d^2 - c - e}{(n + 1)d - c - 2},$$

$$q_j = q_{j-1} - \frac{m_{j-1}}{m_j + \ldots + m_s}$$

for any $2 \leq j < n + 1$. 

Recall that by hypothesis \( m_1 + \ldots + m_s = (n + 1)d - c - 2 \) and \( d > m_k \) for all \( k \). For every \( 2 \leq j \leq n + 1 \), since \( d \geq m_j - 1 \) we obtain
\[
m_j + \ldots + m_s = (n + 1)d - (m_1 + \ldots + m_{j-1}) - 2 - c
= (n + 2 - j)d + (d - m_1) + \cdots + (d - m_{j-1}) - 2 - c
\geq (n + 2 - j)d - c + (j - 3).
\]
From this equality (and \( d \geq m_j - 1 \)) we obtain
\[
q_j = q_{j-1} - r_{j-1} \frac{m_{j-1}}{m_j + \ldots + m_s}
\geq q_{j-1} - r_{j-1} \frac{d - 1}{(n + 2 - j)d - c + (j - 3)}.
\]
Recall \( m_j \geq q_j \), so we obtain
\[
\begin{align*}
m_1 + m_2 + \ldots + m_{n+1} &\geq (q_1 + r_1) + \ldots + (q_n + r_n) + q_{n+1} \\
&\geq (q_1 + r_1) + \ldots + (q_{n-1} + r_{n-1}) + 2q_n + r_n \left(1 - \frac{d - 1}{d - c + (n - 2)}\right) \\
&\geq \sum_{i=1}^{n-2} (q_i + r_i) + 3q_{n-1} + r_{n-1} \left(1 - \frac{2}{2d - c + (n - 3)}\right) + r_n \left(1 - \frac{d - 1}{d - c + (n - 2)}\right) \\
&\geq (n + 1)q_1 + \sum_{k=1}^{n} r_k \left(1 - (n + 1 - k) \frac{d - 1}{(n + 1 - k)d - c + (k - 2)}\right).
\end{align*}
\]
We will now prove that
\[
\begin{align*}
(4.4) \quad 1 - (n + 1 - k) \frac{d - 1}{(n + 1 - k)d - c + (k - 2)} &= \frac{n - 1 - c}{d(n + 1 - k) - c + (k - 2)} \geq 0.
\end{align*}
\]
Indeed, notice that \( c \leq 1 \) implies \( n - 1 - c \geq 0 \) (and equality only for \( n = 2 \) and \( c = 1 \)). Moreover, \( d \geq 2 \) and \( k \leq n + 1 \) imply
\[
d(n + 1 - k) + (k - 2) - c \geq 2(n + 1 - k) + (k - 3)
\geq 2n - k - 1
\geq 1.
\]
Inequalities (4.2), (4.3), and (4.4) imply that
\[
m_1 + \ldots + m_{n+1} \geq (n + 1)q_1
= (n + 1) \frac{d^2(n - 1) - c - e}{(n + 1)d - c - 2}
\]
with equality either if \( m_i \) are equal for all \( i \) (i.e. \( r_1 = 0 \)) or if \( n = 2 \) and \( c = 1 \).
We finally claim that
\[
(4.1) \quad (n + 1) \frac{d^2(n - 1) - c - e}{(n + 1)d - c - 2} > (n - 1)d.
\]

This is equivalent to proving that for all \(-2 \leq c, e \leq 1\), \(n \geq 2\) and \(d \geq 2\) the following inequality holds

\[(c + 2)(n - 1)d > (c + e)(n + 1).\]

This follows since

- If \(c = -2\) then \(0 > (e - 2)(n + 2)\).
- If \(c = -1\) then \((n - 1)d \geq 2(n - 1) > 0 \geq (e - 1)(n + 1)\).
- If \(c = 0\) then \(2(n - 1)d \geq 4(n - 1) > n + 1 \geq e(n + 1)\) since \(n \geq 2 > \frac{5}{3}\).
- If \(c = 1\) then \(3(n - 1)d \geq 6(n - 1) \geq 2(n + 1) \geq (1 + e)(n + 1)\).

Notice equality holds only in the last case \(c = e = 1\) and \(n = d = 2\). However, the \(\mathbb{P}^2\) hypothesis implies \(d^2 - \sum_{k=1}^{s} m_k = 4 - \sum_{k=1}^{s} 1 = 2\) and \(6 - \sum_{k=1}^{s} 1 = 3\) therefore \(s = 3\), so the conclusion holds.

\[\square\]

5. Generalization of Nagata’s correspondence.

In this section we will prove Theorem 0.6, that generalizes Theorem 1.5 (due to Nagata) to \(\mathbb{P}^n\) (see also Remark 3.8) following the approach of Nagata. In [16], Dolgachev has a nice exposition of Nagata’s theorem. Let us first recall Theorem 0.6

**Theorem (=Theorem 0.6).** Let \(i \in \{-1, 0, 1\}\) and \(D\) be a divisor in \(\text{Pic}(X_{n,s})\). Then \(D\) is a divisorial \((i)\) class if and only if it is in the orbit of \(H_{n-1-i}\) a hyperplane passing through \(n - 1 - i\) points under the action of the Weyl group. In particular, the Weyl group acts transitively on the set of divisorial \((-1)\) classes.

It is important to remark that Example 4.1 and Example 3.4 emphasize the importance of the effectivity assumption for the main theorems of the paper, namely Theorems 0.5 and the Nagata correspondence in Theorem 0.6.

The first part of the proof of Theorem 0.6 follows from the following lemma:

**Lemma 5.1.** A general hyperplane passing through \(n - 1 - i\) points, \(H_{n-1-i}\), is a divisorial \((i)\) class for \(i \in \{-1, 0, 1\}\). In particular, \(E_j\) is a divisorial \((-1)\) class for \(1 \leq j \leq s\).

**Proof.** For \(i \in \{-1, 0, 1\}\) we have

\[\langle H_{n-1-i}, H_{n-1-i} \rangle = i\]

\[\frac{1}{n - 1} \langle H_{n-1-i}, -K_{X_{n,s}} \rangle = i + 2\]

Moreover, a general hyperplane \(H_{n-1-i}\) is effective and irreducible. The same argument shows that \(E_j\) is also a divisorial \((-1)\) class.

\[\square\]

Recall that Theorem 2.10 and Proposition 3.9 imply that the Weyl group preserves intersection pairing of Dolgachev-Mukai and divisorial \((i)\) classes. In other words, if \(w \in W_{n,s}\), then we have

- \(\langle w(D), w(F) \rangle = \langle D, F \rangle\).
- If \(D\) is a divisorial \((i)\) class then \(w(D)\) is a divisorial \((i)\) class.

This proves the following corollary.
Corollary 5.2. Let $i \in \{-1, 0, 1\}$. If $D$ is an $(i)$ Weyl divisor, then $D$ is a divisorial $(i)$ class.

For the rest of the proof of Theorem 0.6, it suffices to prove the converse of Corollary 5.2 in $X_{n,s}$.

Proof of Theorem 0.6. Let $D = dH - \sum_{k=1}^{s} m_k E_k \in \text{Pic}(X_{n,s})$.

If $D$ is an $(i)$ Weyl divisor, then $D$ is a divisorial $(i)$ class by Corollary 5.2.

Conversely, assume that $D$ is a divisorial $(i)$ class on $X_{n,s}$. We prove the statement by induction on deg$(D)$.

If $d = 0$, irreducibility assumption implies $D = E_1$ so $i = -1$ and the result follows from Lemma 5.1.

If $d = 1$ all multiplicities are also 1 and the self intersection condition $(n-1) - \sum_{j=1}^{s} m_j = i$ implies that $s = n - 1 - i$. Therefore $D$ is the hyperplane passing through $n - 1 - i$ points.

Assume now that deg$(D) \geq 2$. For convenience order multiplicities increasingly.

If $s \geq n + 1$ then Theorem 0.5 for $c = -1$ and $e = 0$ implies that $m_1 + \ldots + m_{n+1} > (n-1)d$.

Apply a standard Cremona transformation based on points $p_1, \ldots, p_{n+1}$. Equation (2.1) implies that $k > 0$ therefore deg$(\text{Cr} D) < \text{deg} D$. By Proposition 3.9, we see that $\text{Cr} D$ is also a divisorial $(i)$ class of smaller degree. If $\text{Cr} D$ has all multiplicities positive, the induction hypothesis implies $\text{Cr} D \in W_{n,s} \cdot H_{n-1} - i$, and therefore $D \in W_{n,s} \cdot H_{n-1} - i$, where $H_{n-1}$ represents a hyperplane passing through $n - 1 - i$ points.

If, on the other hand, $\text{Cr} D = d'H - \sum_{i=1}^{s} m'_i E_i$ has one multiplicity negative, say $m'_k < 0$, then by irreducibility property of $D$ we must have $m_k = -1$ and for all other $j \neq i$ we have $m'_j = d' = 0$. Thus $\text{Cr} D = E_k$ and $D$ is a hyperplane through $n + 1$ points, skipping the $k$th point (see Equation (2.1)), so in this case is a $(1)$ divisor. In both cases $\text{Cr} D$ is an $(i)$ divisorial class.

Assume deg$(D) \geq 2$ and $s \leq n$. Condition $d \geq m_i$ implies that $(n-1)d \geq \sum_{k=1}^{n-1} m_k \geq 0$, therefore Theorem 0.5 implies $s = n$. Theorem 0.5 also implies that in fact $D$ is not Cremona reduced, therefore $\text{Cr}(D)$ is an irreducible divisor with one multiplicity negative. Therefore $\text{Cr}(D)$ can only be an exceptional divisor (with $i = -1$).

□

Remark 5.3. As Example 4.1 illustrates, Theorem 0.6 does not hold without the effectivity hypothesis of divisorial $(i)$ classes. This is because the condition of Theorem 0.5, namely $d \geq m_k$ for all $1 \leq k \leq s$, is not invariant under Cremona transformations. So without the effectivity hypothesis of the divisors, Theorem 0.5 can not be applied repeatedly.

We now generalize Proposition 1.11 (see also [16] for $n = 2$).
Theorem (=Theorem 0.8). There are no irreducible effective divisors $D$ on $X_{n,s}$ with $\langle D, D \rangle = r \in \{-4, -3, -2\}$ and $\text{adeg}(D) = -2 - r$.

Proof. If such divisor $D$ exists, then $d \geq m_i \geq 0$. Transform such divisors, as in the previous proof, so that $w(D) = H - \sum E_i$. Self intersection condition implies that the number of points satisfies $s \geq n + 1$ and therefore the points are not in general position. We obtain a contradiction. \qed

Corollary 5.4. There are no irreducible effective divisors $D$ on $X_{n,s}$ with $\langle D, D \rangle = 0$ and $\text{adeg}(D) = 1$.

Proof. Assume by contradiction such divisor exists. Apply Theorem 0.5 for $c = -1$ and $e = 1$ to conclude that $D$ is not Cremona reduced. Therefore, one can apply a Weyl group element until $d = 1$, and by effectivity assumption all other multiplicities are at most 1 so $w(D) = H - \sum E_k$. Now $\langle D, D \rangle = (n-1) - q = 0$ implies that $q = n - 1$ but $\text{adeg}(D) = (n+1) - (n-1) = 2 \neq 1$ and this gives a contradiction. \qed

We remark that in the planar case a curve class $C$ on $X_{2,s}$ with $C \cdot C = 0$ and $C \cdot (-K) = 1$ would have arithmetic genus $p_a(C) = \frac{2 \cdot D \cdot (D + K_X)}{2} = 1/2$ that is a contradiction.

6. IRREDUCIBILITY CRITERIUM OF DIVISORIAL ($i$) CLASSES.

In this section, we prove Theorem 0.9, a generalization of Theorem 1.12 of Dumitrescu–Osserman in [13], stating that we can replace the irreducibility assumption by a numerical criterium. Examples 4.1 and 3.4 show that the assumption that divisors be effective is needed in Theorem 0.9.

For reference, let us recall Theorem 0.9.

Theorem (=Theorem 0.9). Let $i \in \{-1, 0, 1\}$. The divisor $D$ is a divisorial $(i)$ class on $X_{n,s}$ if and only if $D$ is effective satisfying numerical conditions (0.2) and for all degrees $0 < d' < d$ and all divisorial $(-1)$ classes $D'$ of degree $d'$ we have $\langle D, D' \rangle \geq 0$.

The proof of the theorem requires the following lemma—a base locus lemma for divisorial $(-1)$ classes, that has not been previously formulated in terms of Dolgachev- Mukai pairing (2.4).

Lemma 6.1 (Base locus lemma). Fix an effective divisor $D$ and let $F$ be a divisorial $(-1)$ class satisfying $-k_F = \langle D, F \rangle < 0$.

Then $F$ is a fixed component of $D$ with multiplicity of containment $k_F > 0$.

Proof. Since $F$ is the divisorial $(-1)$ class, Corollary 5.2 implies that there exist $\omega$ in the Weyl group $W_{n,s}$, so that $F = \omega(E_k)$.
and let \( \delta = \omega^{-1} \in W_{n,s} \) (see Remark 2.6) and denote by \( G := \delta(D) \), an effective divisor by property (4) of Corollary 2.7. By Theorem 2.10

\[
\langle D, F \rangle = \langle D, \omega(E_k) \rangle = \langle \delta(D), (\delta \circ \omega)(E_k) \rangle = \langle G, E_k \rangle
\]

Since \(-k_F = \langle G, E_k \rangle < 0\) we see that \( E_k \) appears as a fixed component of \( G \) with multiplicity \( k_F > 0 \). We conclude that \( F = \omega(E_k) \) appears in the base locus of \( D \) with multiplicity \( k_F > 0 \). □

Example 6.2. Lemma 6.1 holds only for divisorial \((-1)\) classes. Notice that for \( n = 2 \), the multiplicity of containment of a curve in the base locus of a divisor \( D \in \text{Pic}(X_{3,9}) \) is given by intersection pairing only for \(-1\) curves. Indeed, for any positive integer \( m \) let us consider the divisor

\[
D := 3mH - mE_1 - \ldots - mE_9.
\]

Take \( E := 3H - E_1 - \ldots - E_9 \) the unique cubic curve passing through nine points. \( E \) is an elliptic curve (therefore not a \((-1)\) curve) and notice

\[
k_E = D \cdot E = 9m - 9m = 0.
\]

By Ciliberto-Miranda [30] the Gimigliano-Harbourne-Hirschowitz conjecture (1.2) holds when the number of points \( s \) is a perfect square and when all multiplicities are equal. Therefore

\[
\dim H^0(X, \mathcal{O}_X(D)) = \chi(X, \mathcal{O}_X(D)) = \binom{3m+2}{2} - 9 \binom{m+1}{2} = 1.
\]

This implies that projectively \(|D|\) contains just one element, and since \( mE \) is an element of form (6.1) we conclude

\[
D = mE.
\]

We conclude that even though \( k_E = 0 \), the elliptic curve \( E \) is contained in the base locus of \( D \) precisely \( m \) times.

We now proceed with the proof of Theorem 0.9.

Proof of Theorem 0.9. Assume \( D \) is a divisorial \((i)\) class that fails the last condition of the statement of the theorem. Then there exists a divisorial \((i)\) class \( D' \) of degree \( d' \) smaller than \( d \), so that \( \langle D, D' \rangle < 0 \). By Lemma 6.1, \( D' \) is a fixed component of \( D \) so \( D \) can be written as the sum of two divisors \( D' \) and \( D'' \),

\[
D = D' + D''.
\]

This gives a contradiction since \( D \) is irreducible.

Conversely, assume that \( D \) satisfies the conditions (0.2), we will use induction on \( d = \deg D \) to show that \( D \) is irreducible.

1. For the base case \( i = -1, d = 0 \), conditions (0.2) imply that \( m_1 = -1 \) and all other multiplicities are zero, so \( D = E_1 \) a \((-1)\) Weyl divisor by Lemma 5.1 (a similar argument holds for \( d = 1 \)).

2. If \( i \in \{-1, 0, 1\} \) and \( d = 1 \), one obtains \( m_k \geq 0 \) with \((n-1) - \sum_{k=1}^{s} m_k^2 = i \) and also \((n+1) - \sum_{k=1}^{s} m_k = 2 + i \). If you subtract the two equations you obtain \( \sum_{k=1}^{s} m_k \cdot (m_k - 1) = 0 \) ie \( m_k = 1 \) for all \( k \in \{1, \ldots, s\} \).
Therefore we have equality so $s = n - 1 - i$ and $m_k = 1$ for all $k \in \{1, s\}$. For $d = 1$ we concluded that $D$ is an $(i)$ divisorial class via Lemma 5.1.

Let $d \geq 1$. By induction hypothesis we know the theorem holds for all divisors $D'$ of degree $d' < d$. We prove the remainder of the statement contrapositively, namely, assuming $D$ fails the irreducibility condition, we will prove that there exist a divisorial $(i)$ class $D'$ of degree $d' < d$ so that $\langle D, D' \rangle < 0$.

If $D$ is not irreducible then there exist $D_1$ and $D_2$—two effective divisors—satisfying

$$D = D_1 + D_2.$$ 

By Theorem 0.5 for $c = i$ and $e = 0$, there exist indices $i_1, \ldots, i_{n+1}$ so that

$$m_{i_1} + \ldots + m_{i_{n+1}} > (n-1)d$$

Applying a standard Cremona transformation based on set $I = \{i_1, \ldots, i_{n+1}\}$, denote by $\overline{D} = \text{Cr}_I D$. Then $\overline{D}$ is effective, satisfies conditions (0.2) by Theorem 2.10, and has smaller degree than $D$. But $\overline{D}$ is not irreducible since

$$\overline{D} = \text{Cr}_I(D) = \text{Cr}_I(D_1) + \text{Cr}_I(D_2).$$

By the induction hypothesis on $\overline{D}$, there exists a divisorial $(i)$ class $F$, of degree smaller than degree of $F$ so that

$$\langle \overline{D}, F \rangle < 0.$$ 

If $\overline{D}$ has one negative multiplicity then $F$ is one of the exceptional divisors $E_i$. If $\overline{D}$ has all multiplicities positive then perform a standard Cremona transformation on the index set $I$ and denote by $D' := \text{Cr}_I(F)$. Proposition 3.9 implies that $D'$ is a divisorial $(-1)$ class. Theorem 2.10 implies that

$$\langle D, D' \rangle = \langle \text{Cr}_I(D), \text{Cr}(F) \rangle = \langle \text{Cr}(D), F \rangle = \langle \overline{D}, F \rangle < 0.$$ 

This proves the claim. \hfill $\Box$

The next example shows why irreducibility is needed in Definition 3.1 and why last condition of Theorem 0.9 is needed. This is a generalization to dimension three of Example (1.13) of [13].

**Example 6.3.** Take $i \in \{-1, 0, 1\}$ and $D \in \text{Pic}(X_{3,8-i})$.

$$D := 4H - 3E_1 - 3E_2 - 3E_3 - E_4 - \ldots - E_{8-i}$$

Notice that

$$\langle D, D \rangle = 32 - 27 - (5 - i) = i$$

$$\text{adeg } D = \frac{\langle D, -K_{X_{3,8-i}} \rangle}{2} = 16 - 9 - (5 - i) = 2 + i$$

Notice that $D$ is not irreducible. Indeed, let $H_{123}$ denote the hyperplane passing through the first three points. Lemma 6.1 implies that hyperplane $H_{123}$ is a fixed component of $D$ since

$$\langle D, H_{123} \rangle = 8 - (3 + 3 + 3) = -1 < 0.$$
Let
\[ D_1 := D - H_{123} = 3H - 2E_1 - 2E_2 - 2E_3 - E_4 - \ldots - E_{8-i} \]
and notice that \( D_1 \) (and therefore \( D \)) is effective since
\[
\dim H^0(X_{3,8-i}, \mathcal{O}_{X_{3,8-i}}(D_1)) - \dim H^1(X_{3,8-i}, \mathcal{O}_{X_{3,8-i}}(D_1)) = \chi(X_{3,8-i}, \mathcal{O}_{X_{3,8-i}}(D_1)) = \binom{6}{3} - 3 \binom{4}{3} - (5 - i) = 3 + i > 0.
\]

7. Mori Dream Spaces.

We end with a few results about Mori Dream Spaces. As before, let \( X_{n,s} \) denote the blow up of projective space at a collection of \( s \) general points and let \( W_{n,s} \) be the Weyl group of \( X_{n,s} \). It is well known that \( X_{n,s} \) is a Mori Dream Space (MDS) whenever \( s \leq n + 3 \); the birational geometry of this space is studied in [1], [2], [5], and [28]. If \( s \geq n + 4 \), then \( X_{n,s} \) is generally not a MDS with the following notable exceptions:

- all Del Pezzo surfaces \( X_{2,s} \) with \( s \leq 8 \),
- \( X_{3,7} \) and
- \( X_{4,8} \).

In fact, explicit generators are known for the Cox rings in all of these exceptional cases besides the last one see [38].

In [7] the authors study birational properties of MDS and prove that if \( n + 1 \leq s \leq n + 3 \), the movable cone of \( X_{n,s} \) is the intersection between the Effective cone \( \text{Eff}_R(X_{n,s}) \subseteq N^1(X_{n,s})_R \), and the dual of the Effective cone \( \text{Eff}_R(X_{n,s})^\vee \) under the Dolgachev-Mukai pairing. In other words,
\[
\text{Mov}(X_{n,s}) = \text{Eff}_R(X_{n,s}) \cap \text{Eff}_R(X_{n,s})^\vee.
\]

This description of the movable cone relies on an interesting description of the orbit \( W_{n,s} \cdot E_i \); this description is provided in [7, Theorem 4.6], which basically says that if \( n + 1 \leq s \leq n + 3 \), then
\[
W_{n,s} \cdot E_k = \{ D \in \text{Eff}(X_{n,s}) | \text{adeg}(D) = 1 \}.
\]

The next result, Theorem 7.1, strengthens that theorem to include \( s \leq n \).

**Theorem 7.1.** Let \( s \leq n + 3 \), \( n \geq 2 \). Then the orbit of the Weyl group on \( W_{n,s} \) on the exceptional divisor \( E_k \) can be described as
\[
W_{n,s} \cdot E_k = \{ D \in \text{Eff}(X_{n,s}) | \text{adeg}(D) = 1 \}.
\]

**Proof of Theorem 7.1.** Since the case for \( n + 1 \leq s \leq n + 3 \) are presented in [7, Theorem 4.6], we will assume \( s \leq n \). The techniques of proof are similar in this case.

We first consider the Weyl group orbit. By (2.1) and (2.3), the only new elements in the orbit \( W_{n,s} \cdot E_i \) for \( s \leq n \) are the other exceptional divisors \( E_j \) and hyperplanes passing through \( n \) points (skipping the \( i \)-th point). Obviously these elements are effective of anticanonical degree 1.

Conversely, suppose \( D \in \text{Eff}(X_{n,s}) \) satisfies the property \( \text{adeg} D = 1 \). We will act on \( D \) with elements of the Weyl group until its image becomes Cremona reduced.
In other words if we set $D = dH - \sum_{j=1}^{n} m_j E_j$, with $w \in W_{n,s}$ and $w(D) = d'H - \sum_{j \leq n} m'_j E_j$, the we would like to have

$$d'(n-1) - \sum_{j \leq s} m'_j \geq 0.$$  

Notice that if $s \leq n-1$ then $D$ is already Cremona reduced since $m_1 \leq d$. For $s = n$, we can order multiplicities decreasingly i.e. $m'_1 \geq \ldots \geq m'_s$, not necessarily positive (see Remark 2.2). Property (3) of Remark 2.1 implies that $w(D)$ is effective. By Theorem 2.10, we have $\text{adeg} w(D) = 1$.

Then the following inequalities hold

1. $d' \geq 0$,
2. $d' \geq q_1 \geq \ldots \geq m'_s$,
3. $d'(n-1) - \sum_{j \leq s} m'_j \geq 0$,
4. $d'(n+1) = 1 + \sum_{j=1}^{s} m'_j$.

Assume $1 \leq s \leq n$. Conditions (3) and (4) imply that $2d' \leq 1$ therefore $d = 0$ and (2) becomes $0 \geq m'_1 \geq \ldots \geq m'_s$ and (4) reads $\sum_{j=1}^{s} m'_j = -1$. Therefore $m'_s = -1$, i.e. $w(D) = E_s$, so $D = v(E_s) \in W_{n,s} \cdot E_s$. □

Property (4) of Remark 2.1 and $\dim H^0(X_{n,s}, O(E_i)) = 1$ make the following statement obvious.

Remark 7.2. For $X_{n,s}$ then $W_{n,s} \cdot E_i \subset \{ D \in \text{Eff}(X_{n,s}) | \text{adeg}(D) = 1 \}$, the equality of Theorem 7.1 holds only for $s \leq n+3$. We give two relevant examples of divisors on MDS $X_{n,s}$ so that $s \geq n+4$ and Theorem 7.1 doesn’t hold.

1. Consider $D := 3H - \sum_{i=1}^{8} E_i$ on $X_{2,8}$. Divisor $D$ is effective (an elliptic curve) and it has $\text{adeg}(D) = 1$ but $D \notin W_{2,8} \cdot E_i$, since $\langle D, D \rangle = 1$.

2. Consider $D := 2H - \sum_{i=1}^{7} E_i$ on $X_{3,7}$. The divisor $D$ is effective (a quadric surface) and it has $\text{adeg}(D) = 1$ but $D \notin W_{3,7} \cdot E_i$, since $\langle D, D \rangle = 1$.

Remark 7.3. Theorems 0.6 and 7.1 imply that for $s \leq n+3$, if $D \geq 0$, and $\text{adeg} D = 1$, then $D$ is irreducible, and $\langle D, D \rangle = -1$. This is only true for MDS as we have seen.

A natural question to ask is whether any two of the above conditions imply the other two; we saw a similar phenomenon in Lemma 1.7. The answer is generally no. For example, if we consider the divisor $D := 3H - 3E_1 - 3E_2 - 3E_3 - E_4$ in $X_{4,4}$. For this divisor, we have $\langle D, D \rangle = -1$ and $D$ is effective. However, it is easy to see that the divisor $D$ is not irreducible—consisting of the hyperplane through all four points and a quadric double at the first three points—and $\text{adeg} D = \frac{(D, K_{X_{4,4}})}{3} = 5 \neq 1$. 

For a small number of points in two dimensions, the following result is known to hold on $X_{2,s}$ when $s \leq 9$ (for $s = 9$ there is an infinite list of $(-1)$ curves). Notice that this Criterium is much simpler than Theorem 1.12 (see for example [13])

**Lemma 7.4.** If $s \leq 9$, a divisor $D$ on $X_{2,s}$ is a $(-1)$ curve if and only if

\[ D \cdot D = D \cdot K_X = -1. \]

### 7.1. Moduli Problems.

In this section we will briefly describe further motivation for this work, new directions and connections with other topics, especially related to Mori Dream Spaces. Recall that $X_{n,s}$ is a Mori Dream space for $s \geq n + 3$, as well as the spaces $X_{3,7}$ and $X_{4,8}$ and $X_{2,s}$ for $s \leq 8$.

The birational geometry of Mori Dream Spaces can be encoded in finite data, namely rational polyhedral cones together with their Mori chamber decomposition. The chamber decomposition is determined by arbitrary dimensional $(-1)$ classes, which, unlike $(-1)$ curves or divisorial $(-1)$ classes, live on the blow up of $X_{n,s}$ along different subvarieties. Thus studying such classes can be quite difficult. We will now discuss two connections of the Mori Dream Spaces $X_{n,n+3}$ to other interesting constructions, beginning with the moduli space of certain vector bundles. This point of view is discussed, e.g. in [3], [33], and later in [1], [2], [5], [8], [9], [11], [28].

The geometry of the Mori Dream Space $X_{n,n+3}$ was studied first by Mukai and Bauer due to its connection to the moduli space of rank 2 parabolic vector bundles. The birational geometry of the moduli space of rank 2 semistable parabolic vector bundles on a rational curve, in particular the effective cone and all birational models (that correspond to moduli space of parabolic vector bundles with certain weights) was studied in [28].

In order to see the connection, we first fix $n + 3$ points $p_1, \ldots, p_{n+3}$ in $\mathbb{P}^1$. A parabolic rank 2 vector bundle over $\mathbb{P}^1$ is comprised of the following data:

- A vector bundle $E$ of rank 2 over $\mathbb{P}^1$;
- for each $k \in \{1, 2, \ldots, n\}$, a 1-dimensional subspace $V_k \subset E|_{p_k}$;
- a sequence of rational numbers $\vec{a} = (a_1, \ldots, a_n)$ such that $0 \leq a_k < 1$.

The parabolic slope of $E$ is defined to be

\[ \text{pardeg } E := \frac{\sum_{k=1}^{n} a_k}{2}. \]

Two rank 2 semisimple bundles are $S$-equivalent if they have the same factors in their Jordan-Holder filtration. Denote by $\mathcal{M}_S$ the moduli space of rank 2, degree 0 equivalence classes (under $S$-equivalence) of semistable parabolic vector bundles over $\mathbb{P}^1$, with parabolic structure $\vec{a}$.

Bauer in [3] introduced weight polytope $\Delta \subset [0, 1]^{n+3}$—i.e. weights for which the moduli space is non-empty—and studied the chamber decomposition of this space. The moduli space $\mathcal{M}_S$ varies with weights; for some weights it could be either empty, or $\mathbb{P}^n$ or $X_{n,n+3}$. In fact, Bauer in [3] and Mukai in [33] proved that $X_{n,n+3}$ is isomorphic to $\mathcal{M}_S$ where $\vec{a} = \left( \frac{1}{n}, \ldots, \frac{1}{n} \right)$.

The GIT information is encoded in this polyhedral data; the chamber containing the central weight $\left( \frac{1}{2}, \frac{1}{2}, \ldots, \frac{1}{2} \right) \in \Sigma$ determines the other chambers. Furthermore, Mukai in [33] and Araujo and Massarenti in [2, Theorem 3.4] proved that there exist a linear projection $\pi : \mathbb{P}^{n+4} \to \mathbb{R}^{n+3}$ so that

- $\pi(\text{Eff}(X_{n,n+3})) = \Delta$,
- $\pi(\text{Mov}(X_{n,n+3})) = \Sigma \subset \Delta$. 
\[ \pi(-K_{X_{n,n+3}}) = \left( \frac{1}{2}, \ldots, \frac{1}{2} \right) \]

and so that the Mori chamber decomposition of \( \text{Eff}(X_{n,n+3}) \) induces the chamber decomposition of \( \Delta \).

Another interesting birational model for \( X_{n,n+3} \) when \( n \) is even is constructed as follows. Define two quadrics \( Q_1 \) and \( Q_2 \) by the following two equations:

\[
\sum_{k=1}^{n+3} x_k^2 = 0 \quad \sum_{k=1}^{n+3} \lambda_k x_k^2 = 0
\]

Let \( Z := Q_1 \cap Q_2 \subset \mathbb{P}^{n+2} \) denote their complete intersection. Set \( n = 2m \) and let \( G \) be the subvariety of the Grassmannian \( Gr(m-1, \mathbb{P}^{n+2}) \) parametrizing linear cycles of dimension \( m-1 \) contained in \( Z \). Then \( G \) is a smooth \( n \) dimensional Fano variety with Picard number \( n + 4 \) and is isomorphic to \( M_\mathcal{E} \) where \( \mathcal{E} = (\frac{1}{2}, \frac{1}{2}, \ldots, \frac{1}{2}) \) (see [8]). Bauer in [3] and Casagrande in [8] proved that varieties \( G \) and \( X_{n,n+3} \) are strongly birational (i.e. isomorphic in codimension 1).

Furthermore, let us denote by \( \mathcal{M} := \{ M \cong \mathbb{P}^m | M \subset Z \} \) the finite set (with cardinality \( 2^{2m+1} \)) of cycles of dimension \( m \). For every \( M \in \mathcal{M} \), define \( E_M := \{ L = \mathbb{P}^{m-1} | L \cap M \neq \emptyset \} \in \text{Eff}(G) \). The variety \( Z \) has an involution \( \sigma_k \) sending \( x_i \) to \(-x_i \) for each \( k \in \{1,\ldots,n+3\} \). Now fix an element \( M \in \mathcal{M} \), and set \( M_k = \sigma_k(M) \).

Araujo-Casagrande in [1] prove that for a fixed choice of \( M \), there is a unique birational map \( \rho_M : G \to \mathbb{P}^n \) inducing a strong birational map \( G \to X_{n,n+3} \) with the properties that under this map \( E_M \) are sent in the divisorial \((-1)\) classes while \( E_M \) is sent to the secant variety to the unique rational normal curve of degree \( n \) passing through all \( n + 3 \) points in \( \mathbb{P}^n \).

The combinatorial data describing \( X_{n,n+3} \) as a Mori Dream space was also independently identified in [5] by Brambilla-Dumitrescu-Postinghel from a different point of view. Even if extremal rays of the Effective and Movable cones of divisors are known, finding the facets of cone with given rays is in general a difficult combinatorial problem. For \( X_{n,n+3} \), in [5] the authors emphasize that computation of the facets of the Effective and Movable cones of divisors can be computed via geometry determined by divisorial \((-1)\) classes. More precisely, Theorem 5.1 of [3] highlights that the facets of the Effective cone of divisors of \( X_{n,n+3} \) (or Movable cones of divisors) are obtained from the Dolgachev-Mukai pairing with divisorial \((-1)\) classes.

Currently there is no general definition as in Equation (0.2) for arbitrary dimensional \((-1)\) classes; numerical conditions are not known and therefore no rigorous examples on how to construct them. However, in [5] the authors emphasize that cones over the secant variety of a rational normal curve \( J(L_I, \sigma_I) \) dimension \(|I| + 2t - 1 \) (see Section 7) are such \((-1)\) classes determining the chamber decomposition of the movable cone. Also the Mori chamber decomposition of these cones into nef chambers is given by similar conditions where walls are determined by such \((-1)\) classes of arbitrary dimension. So far there is no explanation for why this should be true.

This leads us to the following intuition of how one might define \((-1)\) classes of arbitrary dimension, which gives further motivation to understand the divisorial \((-1)\) classes. We consider \((-1)\) classes to be irreducible components the intersections of distinct divisorial \((-1)\) classes that are orthogonal with respect to the Dolgachev-Mukai pairing.
In [26], Laface and Ugaglia define *elementary* \((-1)\) curves to be the orbit of a line through two points under the Weyl group action. In dimension 3, this is equivalent to the intuitive definition we have just described, however our intuitive definition can be extended to higher dimension.

Let us take \(X_{3,6}\) as an example. Because we are in dimension 3, we consider divisorial \((-1)\) classes, and \((-1)\) classes of dimension 1, which we will call \((-1)\) curves. A \((-1)\) curve be an irreducible curve contained in the intersection of two divisorial \((-1)\) classes on \(X_{3,6}\). As we will later show, this means a \((-1)\) curve is of the form \(w(E_i) \cdot w(E_j)\) for \(w \in W_{3,6}\), the Weyl group of \(X_{3,6}\) as in Remark 2.6. In this example, the only divisorial \((-1)\) classes on \(X_{3,6}\) are the exceptional divisors \(E_i\), hyperplanes through three points \((\text{i.e. the divisor } H - E_p - E_j - E_k)\) and cones over the conic through five points in \(\mathbb{P}^2\), \((\text{i.e. } 2H - 2E_p - \sum_{j \neq p} E_j)\).

In other words, a \((-1)\) curve is either a line through two points \(L_{pj} = H_{pjk} \cdot H_{pjl}\) or is an intersection between two cones as described, namely for some \(i,j \in \{1, \ldots, 6\}\) and \(i \neq j\),

\[
D_k := 2H - 2E_k - \sum_{p \neq k} E_p \\
D_j := 2H - 2E_j - \sum_{p \neq j} E_p.
\]

(7.2)

By the theorem of Bezout, both divisors \(D_k\) and \(D_j\) contain in their base locus the line \(L_{kj}\) passing through the first 2 points. Therefore the intersection between \(D_k\) and \(D_j\) is a reducible curve of degree \(2 \cdot 2 = 4\) and passing through points \(p_k\) and \(p_j\) with multiplicity \(2 \cdot 1 = 2\), and passing through the last four points (multiplicity \(1 \cdot 1 = 1\)). Therefore

\[
D_k \cdot D_j = L_{kj} + C.
\]

and so we deduce that \(C\) has to be the unique rational normal curve in \(\mathbb{P}^3\) of degree \(4 - 1 = 3\) passing through all six points.

Note that the other intersections \(D_p \cdot H_{pjk}\) of orthogonal divisors with respect to Dolgachev-Mukai pairing are reducible and can be expressed as sum of two lines.

From this discussion we see that the birational geometry of \(X_{3,6}\) is determined by divisorial \((-1)\) classes, but also by special surfaces that we will call \((-1)\) surfaces. A finite list of \((-1)\) surfaces together with some of their properties was identified in [9]; we will roughly present it here.
We will begin by relating the geometry of $X_{2,8}$ with $X_{4,8}$, as in [33]. More specifically, let $X_{2,8}$ be the blow up of $\mathbb{P}^2$ at points $q_1, \ldots, q_8$ and $X_{4,8}$ be the blow up of $\mathbb{P}^4$ at $p_1, \ldots, p_8$ general points. These two varieties are connected by Godeaux duality giving a bijection between sets of 8 general points in $\mathbb{P}^2$ and in $\mathbb{P}^4$, up to projective equivalence. The precise relation between $X_{2,8}$ and $X_{4,8}$ was established in the following theorem of Mukai:

**Theorem 7.5.** $X_{4,8}$ is isomorphic to moduli space of rank 2 torsion free sheaves $F$ on $X_{2,8}$ for which $c_1(F) = -K_S$ and $c_2(F) = 2$.

In this theorem, the semistability refers to semistability in the sense of Gieseker-Maruyama with respect to $-K_{X_{2,8}} + 2h$ where $h \in \text{Pic}(X_{2,8})$ is the pull-back of $O_{\mathbb{P}^2}(1)$ under the map $X_{2,8} \rightarrow \mathbb{P}^2$.

Mukai’s proof of this theorem is based on the study of the birational geometry of the moduli space of such rank 2 torsion free sheaves in terms of the variation of the stability condition given by the ample line bundle of $-K_{X_{2,8}} + 2h$.

By studying the geometry of the del Pezzo surface $X_{2,8}$ and transcribing via Mukai’s correspondence, the authors in [9] describe the five types surfaces in $X_{4,8}$ playing a special role in the Mori program:

1. planes passing through three points;
2. cones over one point of the rational normal curve in $\mathbb{P}^3$ passing through seven points;
3. surfaces of degree 6 with three simple points and five triple points;
4. surfaces of degree 10;
5. surfaces of degree 15.

Each of these surfaces comes equipped with certain multiplicities.

However, following the point emphasized in this work, we can explicitly construct Weyl cycles on $X_{4,8}$ as irreducible surfaces contained in the intersection of two divisorial $(-1)$ classes on $X_{4,8}$ that are orthogonal with respect to the Mukai pairing as in [6]. This definition will agree with and extend the $(-1)$ Weyl lines of Laface Ugagila [26]. For example we can take the cones over divisors (7.2) in $X_{3,7}$ with the vertex consisting at one point $p_k$

$$D_{k,q} := 2H - 2E_k - 2E_q - \sum_{p \neq i} E_p$$

$$D_{k,j} := 2H - 2E_k - 2E_j - \sum_{p \neq j} E_p$$

As in the previous example (7.2), we can see the plane determined by points $L_{kq}$ is in the base locus of both divisors $D_{k,q}$ and $D_{k,j}$. Indeed, one can see by Bezout’s theorem that both divisors contain a pencil of lines $L_{k}$ passing through the cone of each divisor and through an arbitrary point point $s$ on line $L_{qj}$.

$D_{k,i}$ and $D_{k,j}$ are two divisorial $(-1)$ classes orthogonal with respect to the Mukai pairing, that intersect along a union of two surfaces of degree $2 \cdot 2$ and multiplicities $m_k = 2 \cdot 2 = 4$, $m_i = 2$ and $m_j = 2$ while all other multiplicities are $m_p = 1 \cdot 1 = 1$. Since plane $L_{kij}$ is in this intersection, the residual surface is of degree 3—i.e. a cone at vertex $P$ over the rational normal curve in $\mathbb{P}^3$ of degree 3 passing through 6 points, $J(P, \sigma_{1}(C))$.

In a similar way one can express explicitly all possible Weyl surfaces using intersection theory in the Chow Ring $A^2(X_{4,8})$ of $X_{4,8}$ along all lines and all rational
normal curves of degree 4 passing through 7 points. A rigorous definition and a classification for \((-1)\) curves and \((-1)\) surfaces on \(X_{4,8}\) was given in [6] and [14]. Surprisingly, these Weyl surfaces correspond to the ones of [9]. Moreover, these Weyl surfaces are also the Weyl group orbit of a plane through 3 fixed points (see [14]). However, it is not known if there is an arithmetic definition similar to (0.2) for arbitrary dimensional \((-1)\) classes on \(X_{n,n}\) (and their relations with \(F\) strata on \(\overline{M}_{0,n}\)).

The current work also is related to understanding the Cox ring of \(\overline{M}_{0,n}\). In [24] Kapranov identified \(\overline{M}_{0,n}\) with a projective variety isomorphic to the projective space \(\mathbb{P}^{n-3}\) successively blown up along \(r\)-dimensional cycles spanned by \((r+1)\)-subsets of a set with \(n-1\) general points, with \(r\) increasing from 0 to \(n-4\). Though we only look at blowing up in a collection of points, there seems to be a relationship between what we will call "sporadic divisors" and generators of the Cox ring of \(\overline{M}_{0,n}\). For example, the first sporadic divisor \(D_1 = 2H - E_1 - E_2 - \cdots - E_9\) discussed in Example 3.10 is very similar to the Keel-Vermiere divisor that is a quadric through 5 points and 4 lines (see e.g. [43]). The Keel-Vermiere divisor together with the boundary divisors are generators of the Cox ring of \(\overline{M}_{0,6}\) (see [10]). A similar statement is true for the second sporadic divisor in Example 3.10. Furthermore, \(\overline{M}_{0,n}\) has been proven to NOT be a Mori Dream Space for \(n \geq 10\) (see e.g. [12], [18], [21]).

This brings up two questions of interest. First, can we expect a correspondence in the world of Cox ring generators of \(\mathbb{P}^{n-3}\) blown up in \(s\) points and of \(\overline{M}_{0,n}\) by some sort of degeneration argument?

And secondly, one can ask if the notion of divisorial \((-1)\) classes can be generalized to the blow up of \(\mathbb{P}^n\) in higher dimensional cycles, as described above, and whether the generators of the Cox ring can be described by numerical conditions as discussed in the current article. This would give some insight into the generators of Cox rings of \(\overline{M}_{0,n}\) through a combinatorics point of view. This problem will be the topic of future work.

7.2. A conjecture on \(X_{n,n+3}\). In general dimension \(n\), few things about classical interpolation problems in \(\mathbb{P}^n\) are known. The only example the authors are aware of is a conjecture similar to Conjecture 1.2 formulated by Laface and Ugaglia in [26] for three dimensional space \(X_{3,4}\). Surprisingly, the mysterious quadric \(D_1\) analyzed in Example 3.10 plays a crucial role there.

Even if Conjecture 1.2 is not formulated in arbitrary dimension for \(s\) general, in [5] the following conjecture is stated for \(s = n + 3\) points. We will briefly describe its flavor below.

Choose \(t\) arbitrary points on a rational normal curve of degree \(n\) passing through \(n+3\) points, and take the linear span of these \(t\) points; this linear span is isomorphic to \(\mathbb{P}^{t-1}\). Define \(\sigma_t\) to be the secant variety defined as the union of all such spans, \(\mathbb{P}^{t-1}\) together with their closure (which consists of all these \(\mathbb{P}^{t-1}\) that are tangent to the rational normal curve). Let \(J(L_t, \sigma_t)\) denote cones over \(\sigma_t\).

For \(s = n + 3\) points, the elements of the Weyl group orbit \(W_{n,s} \cdot E_9\) encode a beautiful geometry. These divisors are identified with cones \(J(L_t, \sigma_t)\) when the cone vertex \(I\) has cardinality \(n - 2t\) (see for example [2], [5]).

Denote the dimension of the cone variety \(J(L_t, \sigma_t)\) by

\[ r_{t, \sigma_t} := \dim(J(L_t, \sigma_t)) = \dim(L_t) + \dim(\sigma_t) + 1 = |I| + 2t - 1. \]
and the multiplicity of containment of the variety $J(L_I, \sigma_t)$ in base locus of $D = dH - \sum_{p=1}^{s} m_pE_p$ by

$$k_{I, \sigma} := t\left(\sum_{i=1}^{n+3} m_i\right) + \sum_{p \in I} m_p - ((n + 1)t + |I| - 1)d.$$

A similar conjecture to Remark 1.3 for arbitrary $n$ is

**Conjecture 7.6** (Brambilla-Dumitrescu-Postinghel). If $s \leq n + 3$ then

$$\dim H^0(X_{n,s}, \mathcal{O}(D)) = \sum_{I, \sigma_t} (-1)^{|I|} \binom{n + k_{I, \sigma_t} - r_{I, \sigma_t} - 1}{n},$$

where the sum ranges over all indexes $I \subset \{1, \ldots, n+3\}$ and $t$ such that $0 \leq t \leq l + \epsilon$, $n = 2l + \epsilon$ and $0 \leq |I| \leq n - 2t$.

The cones $J(L_I, \sigma_t)$ are the elements of the Weyl group orbit $W_{n,s}$ on the (proper transform) of a linear subspace passing through $r_{I, \sigma_t} - 1$ points of the set $\{p_1, \ldots, p_{n+3}\}$ (work in progress).
