Abstract. Let $X_k$ be the space of analytic, critical circle homeomorphisms with an irrational rotation number $k = [k; k; \ldots; k; \ldots]$. It is shown [S. Ostlund, D. Rand, J. Sethna and E. Siggia, Physica D, 8 (1983) 303] that the renormalization operator $R$ defined on $X_k$ has a unique fixed point $T_0$. In this paper, we study the properties of orbits of a critical point and build a potential for $T_0$.

1. Introduction and results
Historically, ergodic theory was a branch of thermodynamics and statistical mechanics. Although we will not describe the precise relationships between thermodynamics and ergodic theory (see Ruelles book [10] in the references for this), the connections motivate several interesting constructions which turn out to have much wider applications. This is the heart of thermodynamic formalism.

The introduction of thermodynamic formalism within the mathematical field of dynamical systems occurred in the 1970s, and was primarily due to Y. Sinai, D. Ruelle and R. Bowen. In this paper we build the thermodynamic formalism for the circle maps with a critical point. The thermodynamic formalism for the unimodal Feigenbaum map was built by E. Vul, Y. Sinai and K. Khanin [1]. In fact, our work is an analogy of their work for the critical circle maps.

Let us define a set of real-analytic commuting pairs that corresponds to a set of real-analytic critical circle homeomorphisms the order of three. To do this, consider the pairs $(\xi; \eta)$ satisfying the following conditions:

(a) both $\xi$ and $\eta$ are real-analytic, strictly increasing on $[\eta(0), 0)$ and $[0, \xi(0))$ respectively and $\xi(0) = \eta(0) + 1$;
(b) $\xi$ and $\eta$ commute at zero, that is $\eta(\xi(0)) = \xi(\eta(0))$;
(c) both $\xi$ and $\eta$ has the cubic critical point at zero, that is $\xi'(0) = \eta'(0) = \xi''(0) = \eta''(0) = 0$, $\xi'''(0), \eta'''(0)$ are non zero;
(d) $(\eta(\xi))'''(0) = (\xi(\eta))'''(0)$.

The pair $(\xi, \eta)$ is called the critical commuting pair (shortly commuting pair). A commuting pair is called non-generated if $0 < \xi(0) < 1$. For a non-generated commuting pair $(\xi, \eta)$ we define its the height $h(\xi, \eta) \in \mathbb{N}_0 \cup \{\infty\}$ as $m$ if

$$\xi(\eta(0)) < 0, \xi^2(\eta(0)) < 0, \ldots, \xi^{m-1}(\eta(0)) < 0, \xi^m(\eta(0)) > 0$$
and \( h(\xi, \eta) = \infty \) if no such \( m \) exists (note that in this case the map \( \xi \) has a fixed point) where \( \xi^i \) is the \( i \)th iteration of \( \xi \). A non-generated commuting pair \((\xi, \eta)\) is called renormalizable if its height in finite and nonzero. Denote by \( X \) the set of all renormalizable commuting pairs. On \( X \) we define a renormalization operator \( \mathcal{R} \) as follows

\[
\mathcal{R}(\xi, \eta) = (\alpha_m \circ \xi^{m-1} \circ \eta \circ \alpha_m^{-1}, \alpha_m \circ \xi^{m-1} \circ \eta \circ \xi \circ \alpha_m^{-1})
\]

where \( \alpha_m(z) = (\xi^{m-1}(\eta(0)) - \xi^m(\eta(0)))^{-1}(z) \). A commuting \((\xi, \eta) \in X\) is called infinitely-renormalizable if \( \mathcal{R}^n(\xi, \eta) \) is renormalizable for all \( n \in \mathbb{N}_0 \). For a infinitely-renormalizable commuting \((\xi, \eta)\) we define its rotation number \( \rho(\xi, \eta) \in [0, 1) \), by substituting its consecutive heights for partial quotients in the continued fractions expansion \( \rho(\xi, \eta) = [m_1, m_2, ..., m_n, ...] \) where \( m_n \) is the height of \( \mathcal{R}^n(\xi, \eta) \). Actually, the rotation number \( \rho(\xi, \eta) \) of the pair \((\xi, \eta)\) can be defined by dynamical approach as follows. Let \( T_{\xi, \eta} \) be a circle homeomorphism generated by \((\xi, \eta)\) defined on the unit circle \([\eta(0), \xi(0)]\) as follows

\[
T_{\xi, \eta}(x) = \begin{cases} 
\xi(x), & \text{if } x \in [\eta(0), 0), \\
\eta(x), & \text{if } x \in [0, \xi(0)).
\end{cases}
\]

One can easily check that the homeomorphism \( T_{\xi, \eta} \) is an analytic circle homeomorphism and has the cubic critical point at zero. It is well known since Poincaré (1885), that the orbit structure of \( T_{\xi, \eta} \) is determined by some irrational constant \( \rho(T_{\xi, \eta}) \) so called the rotation number of \( T_{\xi, \eta} \), in the following sense: for any point \( x \) of the circle, the mapping \( T_{\xi, \eta}^j(x) \to j \rho(T_{\xi, \eta}) \mod 1, j \in \mathbb{Z} \) is orientation-preserving. One can easily verify that \( \rho(T_{\xi, \eta}) = \rho(\xi, \eta) \).

Further, consider the infinitely-renormalizable commuting pairs \((\xi, \eta)\) whose the rotations numbers \( \rho(\xi, \eta) \) equal to \( \rho_k = [k, k, ..., k, ...] \) for some \( k \geq 1 \). The set of all such commuting pairs is denoted by \( X_k \). R. Ostlund et. al [9] proved that the renormalization operator \( \mathcal{R} \) acting on \( X_k \) has the unique fixed point \((\xi_0, \eta_0)\). Let us recall the following definition.

**Definition 1.1.** Two orientation-preserving circle homeomorphisms \( T_1 \) and \( T_2 \) are said to be \( C^r \) conjugate, \( r \geq 1 \), if there exists an orientation-preserving circle homeomorphism \( H \in C^r(S^1) \) (if \( r \geq 1 \), then it is required that \( H^{-1} \in C^r(S^1) \) such that

\[
H \circ T_1 = T_2 \circ H.
\]

Denote by \( E(T_0) \) the set of all circle homeomorphisms whose are \( C^1 \) conjugated with \( T_k \) and defined on the standard circle \( S^1 \). It is well known (see [3]) that any two topological conjugated homeomorphisms have same rotation number. Therefore, the rotation numbers of homeomorphisms of \( E(T_0) \) are the same and equal to \( \rho_k \).

The purpose of this paper is to build thermodynamic formalism for the set \( E(T_0) \). To formulate our main result, we introduce further notations. Let

\[
\begin{align*}
p_n &= \underbrace{[k,k,\ldots,k]}_{n \text{ times}} \\
q_n &= \underbrace{[k,k,\ldots,k,\ldots,k]}_{n \text{ times}}
\end{align*}
\]

be the sequence of rational convergents of the continued fraction \( \rho_k = [k, k, ..., k, ...] \). The coprime numbers \( p_n \) and \( q_n \) satisfy the recurrence relations \( p_n = kp_{n-1} + p_{n-2} \) and \( q_n = kq_{n-1} + q_{n-2} \) for \( n \geq 1 \), where, for convenience we set \( p_0 = 0, q_0 = 1 \) and \( p_{-1} = 1, q_{-1} = 0 \). Taking the critical point \( x_0 = 0 \), we define the \( n^{th} \) fundamental segment \( I_0^n := I_0^n(x_0) \) as the circle arc \([x_0, T_0^{q_n}(x_0)]\) if \( n \) is even and \([T_0^{q_n}(x_0), x_0]\) if \( n \) is odd. Certain number of images of fundamental segments \( I_0^{n-1} \) and \( I_0^n \), under iterates of \( T_0 \), cover whole circle without overlapping beyond the endpoints and form the \( n^{th} \) dynamical partition of the circle

\[
\mathbb{P}_n := \mathbb{P}_n(x_0, T_0) = \left\{ I_j^i := T_0^j(I_0^i), \ 0 \leq j < q_{n-1} \right\} \cup \left\{ I_{i+1}^{n-i-1} := T_0^i(I_0^{n-1}), \ 0 \leq i < q_n \right\}.
\]
Obviously, the partition \( \mathbb{P}_{n+1} \) is a refinement of the partition \( \mathbb{P}_n \). Indeed, the "short" intervals \( I^n_j \) are members of \( \mathbb{P}_{n+1} \) and each "long" interval \( I^{n-1}_i \in \mathbb{P}_n \), \( 0 \leq i < q_n \), is partitioned into \( k+1 \) intervals belonging to \( \mathbb{P}_{n+1} \) such that

\[
I^{n-1}_i = I^{n+1}_i \cup \bigcup_{s=0}^{k-1} I^n_{i+q^n-1+sq_n}.
\] (1.2)

Next, using the sequence of dynamical partition \( (\mathbb{P}_n)_n \), we introduce a certain symbolic representation for the dynamics of \( T_0 \) as follows. Let \( \mathcal{A} = \{0, 1, \ldots, k\} \) be an alphabet. Consider the set of infinite words \( \mathcal{L} = \{\vec{a} := (a_1, a_2, \ldots, a_n, \ldots) : |a_i| \in \mathcal{A}\} \) corresponding to \( S^1 \setminus \mathcal{O}_{T_0}(x_0) \), where \( \mathcal{O}_{T_0}(x_0) = \{x_0, T_0(x_0), \ldots\} \), and defined as follows. Take an arbitrary point \( x \in S^1 \setminus \mathcal{O}_{T_0}(x_0) \) we associate the unique word \( \vec{a} := (a_1, a_2, \ldots, a_n, \ldots) \) defined inductively as: \( a_n = a \) if \( x \in I^n_j \), \( 0 \leq j < q_n \); \( a_n = k - s \) if \( x \in I^n_{j+q^n-1+sq_n} \), \( 0 \leq i < q_n \), \( 0 \leq s \leq k - 1 \); and \( a_n = 0 \) if \( x \in I^{n+1}_i \), \( 0 \leq i < q_n \). Thus, we obtain a one-to-one correspondence

\[
S^1 \setminus \mathcal{O}_{T_0}(x_0) \leftrightarrow \mathcal{L}.
\]

Notice that, the finite word \( (a_1, a_2, \ldots, a_n) \) of the length \( n \) corresponds to an interval \( I^n \) of the dynamical partition \( \mathbb{P}_n \). We set \( I^n = I(a_1, a_2, \ldots, a_n) \). Denote by \( \lambda_0 \) a probability measure on the space of sequences \( \mathcal{L} \) induced by Lebesgue measure on the circle, namely, \( \lambda_0(a_1, a_2, \ldots, a_n) = |I(a_1, a_2, \ldots, a_n)| \). Consider another space of one-sided sequences,

\[
\Omega_+ = \{\vec{e} = (\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n, \ldots) : \varepsilon_i \in \mathcal{A} \text{ and } \varepsilon_{i+1} = 0 \text{ iff } \varepsilon_i = a, i \geq 1\}.
\]

Now, consider another \( \tilde{T} \in E(T_0) \). Since \( \tilde{T} \) and \( T_0 \) are topological conjugated the sets \( \mathcal{O}_{T_0}(x_0) \) and \( \mathcal{O}_{\tilde{T}}(y_0) \) have the same order, where \( y_0 = H(x_0) \) and \( H \) is the conjugation between \( \tilde{T} \) and \( T_0 \). Therefore, the symbolic representations of the points \( x \in S^1 \setminus \mathcal{O}_{T_0}(x_0) \) and \( H(x) \in S^1 \setminus \mathcal{O}_{\tilde{T}}(y_0) \) are the same in \( \mathcal{L} \) i.e., there exists a unique \( \vec{a} \in \mathcal{L} \) such that \( \vec{a} = \psi(x) \) and \( \vec{a} = \psi(H(x)) \). We set

\[
\Delta^n = H(I^n) \quad \text{and} \quad V_1 := \Delta^1 \cup \Delta^2. \quad \text{Our main result is the following result.}
\]

**Theorem 1.2.** For any \( T \in E(T_0) \) there exists a continuous (in the Tychonoff topology) mapping \( U : \Omega_+ \to \mathbb{R}^1 \) such that the following properties hold.

1. For any \( \vec{e} = (\varepsilon_1, \varepsilon_2, \varepsilon_{p+1}, \ldots, \varepsilon_n, \ldots) \) and \( \vec{b} = (\varepsilon_1, \varepsilon_p, b_{p+1}, \ldots, b_n, \ldots) \) belonging to the space \( \Omega_+ \), there exists a constant \( C_1 = C_1(T) > 0 \) such that

\[
|U(\vec{e}) - U(\vec{b})| \leq C_1|a_k|^{-p}
\] (1.3)

where \( a_k = (\xi^{k-1}(\eta(0)) - \xi^k(\eta(0)))^{-1} \).

2. Let \( I(a_1, \ldots, a_{r+1}, \ldots, a_n) \subset I(a_1, \ldots, a_r) \subset V_1 \), \( 1 \leq r < n \). Then

\[
\frac{|I(a_1, \ldots, a_n)|}{|I(a_1, \ldots, a_r)|} = \left(1 + \psi_1(a_1, \ldots, a_n)\right) \cdot \exp\left\{\sum_{s=r+1}^{n} U(a_s, a_{s-1}, \ldots, a_r, a_1, \vec{\gamma}(a_1))\right\}
\] (1.4)

where \( |\psi_1(a_1, \ldots, a_n)| \leq \text{const} \cdot |a_k|^{-p} \).

**Remark 1.3.** Theorem 1.2 generalizes the main theorem of [2].
The second assertion of Theorem 1.2 implies that, the length of any interval $I^n \in \mathbb{P}_n$ can be expressed in the "Gibbs" form:

$$\text{const} \leq \exp \left\{ \sum_{s=1}^{n} U(a_s, a_{s-1}, \ldots, a_1) \right\} \leq \text{Const.}$$

Following the terminology of statistical mechanics, we call $U$ the potential corresponding to the map $T$. Due to Theorem 1.2 the potential depends on the long-range variables exponentially weakly, i.e., on the statistical mechanical point of view, it is "good".

One can easily verify that the potential $U$ is unique and invariant under a smooth change of variable.

2. Metrical properties of the orbit of critical point

As we have mentioned above the homeomorphism $T_0$ is analytic, has the cubic critical point $x_0 = 0$ and its rotation number is irrational. Due to Yoccoz’s [3] theorem $T_0$ and the linear rotation $T_{\rho_k}(x) = x + \rho_k \mod 1$ are topological equivalent. Hence the topological properties of $T_0$ and $T_{\rho_k}$ are the same. In this section we study the metric properties of the $T_0$-orbit of the critical point $x_0 = 0$. We note that the commuting pair $(\xi_0, \eta_0)$ is a fixed point of renormalization operator $R$ i.e.,

$$\begin{cases} 
\xi_0 = \alpha_k \circ \xi_0^{k-1} \circ \eta_0 \circ \alpha_k^{-1} \\
\eta_0 = \alpha_k \circ \xi_0^{k-1} \circ \eta_0 \circ \alpha_k^{-1}
\end{cases}$$

where $\alpha_k(z) = \alpha_k z$ and $\alpha_k = [\xi_0^{k-1}(\eta_0(0)) - \xi_0^{k}(\eta_0(0))]^{-1}$. We use this fact in the proof of the following theorem.

**Theorem 2.1.** The following relations hold

$$T_0^n(\alpha_k^{-n} x) = \alpha_k^{-n} \xi_0(x), \quad x \in [\eta_0(0), 0), \quad (2.2)$$

$$T_0^{n+q-1}(\alpha_k^{-n} x) = \alpha_k^{-n} \eta_0(x), \quad x \in [0, \xi_0(0)) \quad (2.3)$$

for all $n \geq 1$.

**Proof.** We prove the theorem by induction. Let $x \in [\eta_0(0), 0)$. If $n = 1$, then $q_1 = k$ and $\alpha_k^{-1}(x) \in [0, \xi_0(0))$. Therefore $T_0^1(\alpha_k^{-1} x) = T_0^1(\alpha_k^{-1} x) = T_0^{k-1}(T_0^1(\alpha_k^{-1} x)) = T_0^{-1}(\eta_0(\alpha_k^{-1} x))$. Since $\eta_0(\alpha_k^{-1} x) \in [\eta_0(0), \eta_0(\xi_0(0)))$ we get

$$T_0^{k-1}(\eta_0(\alpha_k^{-1} x)) = \xi_0^{-1}(\eta_0(\alpha_k^{-1} x)) \quad (2.4)$$

Relation (2.1) implies $\xi_0^{-1}(\eta_0(\alpha_k^{-1} x)) = \xi_0^{-1}(\xi_0(\alpha_k^{-1} x))$. Hence

$$T_0^n(\alpha_k^{-1} x) = \alpha_k^{-n} \xi_0(x). \quad (2.5)$$

Suppose, the equation (2.2) holds $k \leq n$. The relations (2.1) and $q_{n+1} = kq_n + q_{n-1}$ imply

$$T_0^{n+1}(\alpha_k^{-n+1} x) = T_0^{kq_n+q_{n-1}}(\alpha_k^{-n+1} x) = T_0^{kq_n}(T_0^{q_{n-1}}(\alpha_k^{-n} \alpha_k^{-2} x))$$

$$= T_0^{kq_n}(\alpha_k^{-n} \xi_0(\alpha_k^{-2} x)) = T_0^{(k-1)q_n}(T_0^{q_n}(\alpha_k^{-n} \alpha_k \xi_0(\alpha_k^{-2} x)))$$

$$= T_0^{(k-1)q_n}(\alpha_k^{-n} \xi_0(\alpha_k \xi_0(\alpha_k^{-2} x))) = T_0^{(k-1)q_n}(\alpha_k^{-n} \eta_0(\alpha_k^{-1} x))$$

$$= T_0^{(k-2)q_n}(T_0^{q_n}(\alpha_k^{-n} \eta_0(\alpha_k^{-1} x))) = T_0^{(k-2)q_n}(\alpha_k^{-n} \xi_0(\eta_0(\alpha_k^{-1} x)))$$

$$\vdots$$

$$= T_0^{kn}(\alpha_k^{-n} \xi_0^{-2} \circ \eta_0(\alpha_k^{-1} x)) = \alpha_k^{-n} \alpha_k^{-1} \xi_0(x) = \alpha_k^{-(n+1)} \xi_0(x).$$

This proves the first assertion of theorem. The proof of the second assertion is similar.
As a consequence of Theorem 2.1 we have.

**Corollary 2.2.** Let \( x_0 = 0 \) and \( x_i = T_i^0 x_0, \ i \geq 1 \). We have

\[ x_{qn+1} = \alpha_k^{-n} x_1 \]

for all \( n \geq 1 \).

Let \( A_n \) be a subset of \( \mathcal{O}_T(x_0) \) which is generation the \( n^{th} \)-dynamical partition i.e., \( A_n = \{x_0, x_1, \ldots, x_{q_n+n-1}\} \). We set

\[
A_n^{(1)} = A_n \cap [0, \xi_0(0)), \quad A_n^{(\ell+1)} = A_n \cap [x_\ell, x_{\ell+1}],
\]

\[
A_n^{(1-1)} = A_n \cap [0, x_{q_1+q_0}), \quad A_n^{(1,2)} = A_n \cap [x_{q_1+q_0}, \xi_0(0)),
\]

where \( 1 \leq \ell \leq k \). It is clear, that \( A_n = \bigcup_{\ell=1}^{k+1} A_n^{(\ell)} \) and \( A_n^{(1)} = A_n^{(1,1)} \cup A_n^{(1,2)} \). Using the definition of \( A_n^{(i)} , i = 1, k + 1 \) and the structure of dynamical partition one can show that

\[
|A_n^{(i)}| = q_{n-1} + q_{n-2}, \quad 1 = 1, k, \quad |A_n^{(k+1)}| = q_{n-2} + q_{n-3}, \tag{2.7}
\]

where \( |\cdot| \) - the cardinality of the finite set. The next theorem describes the transition from \( A_n \) to \( A_{n+1} \).

**Theorem 2.3.** For all \( n \geq 1 \) the following relations hold.

\[
A_n^{(k+1)} = \alpha_k^{-1} \left( A_n^{(1)} \cup \xi_0(0) \right), \quad A_n^{(\ell+1)} = \xi_0^{-1} \left( \eta(A_n^{(1)}) \right), \quad 1 \leq \ell \leq k - 1,
\]

\[
A_n^{(1,1)} = \alpha_k^{-1} \left( \bigcup_{i=1}^{k} A_n^{(i+1)} \right), \quad A_n^{(1,2)} = \xi_0 \left( A_n^{(k+1)} \right) = \xi_0 \left( \alpha_k^{-1} A_n^{(1)} \right).
\]

**Proof.** This theorem is also proved by induction. Assertion of the theorem can be easily verified for \( n = 1 \). We rewrite \( A_n \) and \( A_{n+1} \) as

\[
A_n = A_{n-1} \cup (A_n \setminus A_{n-1}), \quad A_{n+1} = A_n \cup (A_{n+1} \setminus A_n).
\]

By the induction hypothesis, the assertion of Theorem 2.3 is true for \( A_{n-1} \) and \( A_n \). On the other hand, \( A_{n-1} \) is a subset of \( A_n \) and this a subset of \( A_{n+1} \). Consequently, it is enough to prove the assertions of Theorem 2.3 for \( A_n \setminus A_{n-1} \) and \( A_{n+1} \setminus A_n \). Using the definition of \( A_n \) we get

\[
A_n \setminus A_{n-1} = \left\{ x_{q_0+q_{n-1}}, x_{q_0+q_{n-1}+1}, \ldots, x_{q_{n-1}+q_{n-1}} \right\},
\]

\[
A_{n+1} \setminus A_n = \left\{ x_{q_{n-1}+q_{n-2}}, x_{q_{n-1}+q_{n-2}+1}, \ldots, x_{q_{n-2}+q_{n-2}} \right\},
\]

\[
|A_n^{(j)} \setminus A_n^{(j)}| = k q_{n-1}, \quad 1 \leq j \leq k, \quad |A_n^{(k+1)} \setminus A_{n+1}^{(k+1)}| = k q_{n-2}.
\]

Consider the first element \( x_{q_0+q_{n-1}} \) of \( A_{n+1} \setminus A_n \). By Theorem 2.1

\[
x_{q_0+q_{n-1}} = \alpha_k^{-1} x_{q_0+q_{n-1}+q_{n-2}}.
\]

So, the first element of \( A_{n+1} \setminus A_n \) obtains from the first element of \( A_n \setminus A_{n-1} \) by multiplying \( \alpha_k^{-1} \). We pass to the second element of \( A_{n+1} \setminus A_n \). Here, depending on the sign of \( x_{q_{n-1}+q_{n-2}} \) there are two possibilities: either \( x_{q_{n-1}+q_{n-2}} \in [\eta_0(0), 0) \) or \( x_{q_{n-1}+q_{n-2}} \in [0, \xi_0(0)) \).
(a) if \( x_{q_{n-1}+q_{n-2}} \in [\eta_0(0), 0) \) then by Theorem 2.1 we have
\[
x_{q_{n}+q_{n-1}+1} = T_0(x_{q_{n-1}+q_{n-2}}) = T_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}}) = \xi_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}}) \in [x_{q_{n}+q_{0}}, \xi_0(0)),
\]
\[
x_{q_{n}+q_{n-1}+2} = T_0(\xi_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}})) = \eta_0(\xi_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}})) \in [x_1, x_2),
\]
\[
x_{q_{n}+q_{n-1}+3} = T_0(\eta_0(\xi_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}}))) = \xi_0(\eta_0(\xi_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}}))) \in [x_2, x_3),
\]
\[
\ldots \ldots \ldots \ldots
\]
\[
x_{q_{n}+q_{n-1}+k+1} = T_0(\xi_0^{-k}(\eta_0(\xi_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}})))) = \xi_0^{-k}(\eta_0(\xi_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}}))) = \alpha_k^{-1}\eta_0(x_{q_{n-1}+q_{n-2}}) = \alpha_k^{-1}x_{q_{n-1}+q_{n-2}}+1 \in [0, \xi_0(0)).
\]

(b) if \( x_{q_{n-1}+q_{n-2}} \in [\eta_0(0), 0) \) then again Theorem 2.1 we have
\[
x_{q_{n}+q_{n-1}+1} = T_0(x_{q_{n-1}+q_{n-2}}) = T_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}}) = \eta_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}}) \in [x_1, x_2),
\]
\[
x_{q_{n}+q_{n-1}+2} = T_0(\eta_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}})) = \xi_0(\eta_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}})) \in [x_2, x_3),
\]
\[
\ldots \ldots \ldots \ldots
\]
\[
x_{q_{n}+q_{n-1}+k+1} = \xi_0^{-k}(\eta_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}})) = \alpha_k^{-1}\xi_0(x_{q_{n-1}+q_{n-2}}) = \alpha_k^{-1}x_{q_{n-1}+q_{n-2}}+1.
\]

Continue this process one can show that any element of \( A_n \setminus A_{n-1} \) obtains by multiplying \( \alpha_k^{-1} \) to an element of \( A_{n+1} \setminus A_n \). Moreover, with the same manner as in (a) and (b) one can show that for each element of \( x_{q_{n}+q_{n-1}+j} \), \( 0 \leq j \leq kq_n-1 \), there exists an element \( x_{q_{n-1}+q_{n-2}+i} \) in
\[
B_p := \{ x_{q_{n-1}+q_{n-2}}, x_{q_{n-1}+q_{n-2}+1}, \ldots, x_{q_{n-1}+q_{n-2}+p} \}
\]
where \( p > 1 \), such that: either \( x_{q_{n}+q_{n-1}+j} = \alpha_k^{-1}x_{q_{n-1}+q_{n-2}+i}, \) or \( x_{q_{n}+q_{n-1}+j} = \xi_0^{-t}(\eta_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}+2})), \) \( t \leq j \leq t+k-2 \), or \( x_{q_{n}+q_{n-1}+j} = \xi_0^{-t}(\eta_0(\alpha_k^{-1}x_{q_{n-1}+q_{n-2}+1})), \) \( t \leq j \leq t+k-2 \). Next we show that \( B = A_n \setminus A_{n-1} \). To do this it is enough to show \( p = kq_n-1 \). A simple calculation shows that
\[
|B \cap (0, \xi(0))| = |(A_{n+1} \setminus A_n) \cap [x_{q_1}, 0]| = q_n-1 + q_{n-2};
\]
\[
|B \cap (x_{q_1}, 0)| = |(A_{n+1} \setminus A_n) \cap [x_{q_1}, \xi(0)]| = kq_n-1;
\]
\[
|B \cap (x_{q_1}+\eta_0, \xi(0))| = |(A_{n+1} \setminus A_n) \cap [\eta(0), x_2]| = kq_n-1;
\]
\[
\ldots \ldots \ldots \ldots
\]
\[
|B \cap (x_{k-2}, x_{k-1})| = |(A_{n+1} \setminus A_n) \cap (x_{k-1}, x_k)| = kq_n-1.
\]

Similarly
\[
|B \cap [\eta(0), 0)| = |(A_{n+1} \setminus A_n) \cap [0, x_{q_1}+\eta_0]| = kq_n-1 - kq_{n-2};
\]
\[
|B \cap (\eta(0), x_2)| = |(A_{n+1} \setminus A_n) \cap (x_2, x_3)| = kq_n-1.
\]

Using these equations one can show that \( |B \cap [\eta(0), \xi(0)]| = kq_n-1 - kq_{n-2} + kq_{n-2} = kq_n-1 \). This implies \( |B| = |(A_{n+1} \setminus A_n)| = kq_n-1 \). Theorem 2.3 is proved.

Next we estimate the ratio of lengths of two intervals of dynamical partitions.

**Lemma 2.4.** Let \( I^n \in \mathbb{P}_n \) and \( I^{n-m} \in \mathbb{P}_{n-m} \), \( n > m \) such that \( I^n \subset I^{n-m} \). There exists a constant \( C = C(T_0) > 0 \) such that
\[
\frac{I^n}{I^{n-m}} \leq C|\alpha_k|^{-m}, \quad |\alpha_k|^{-3n} \leq C|I^n_0|.
\]
Proof. The proof of lemma follows closely that of [1] for the Feigenbaum map. \qed

To formulate our next result we define some subsets of $\mathbb{P}_n$ as follow

$$\mathbb{P}^{(1)}_n = \left\{ I^n \in \mathbb{P}_n : \text{ such that } I^n \subset [y_0(0), 0] \right\},$$

$$\mathbb{P}^{(2)}_n = \left\{ I^n \in \mathbb{P}_n : \text{ such that } I^n \subset [0, \xi_0(0)] \right\},$$

$$\mathbb{P}_{n,i} = \left\{ I^n \in \mathbb{P}_n : \text{ such that } I^n \subset I_i^0 \right\},$$

where $i = (n - m - 1), (n - m)$. The following theorem plays an important role to build the thermodynamical formalism for $T_0$.

**Theorem 2.5.** The following relations hold, for any $0 < m < n$.

$$\mathbb{P}_{n,n-m} = \alpha_k^{-(n-m)} \mathbb{P}^{(1)}_m,$$

$$\mathbb{P}_{n,n-m-1} = \alpha_k^{-(n-m)} \mathbb{P}^{(2)}_m$$

if $(n - m)$ is an odd number.

$$\mathbb{P}_{n,n-m-1} = \alpha_k^{-(n-m)} \mathbb{P}^{(2)}_m,$$

$$\mathbb{P}_{n,n-m} = \alpha_k^{-(n-m)} \mathbb{P}^{(1)}_m$$

if $(n - m)$ is an even number.

Proof. The proof of theorem follows from Theorem 2.3. \qed

Consider the interval $V_1^{n-m} = I_1^{n-m} \cup I_1^{n-m+1}$. Notice that this interval is a neighborhood of the point $x_1$. Further, taking two intervals $I'$ and $I$ such that $I' \subset I \subset V_1^{n-m}$ and $I' \in \mathbb{P}_{n+1}$, $I \in \mathbb{P}_n$ we provide an estimate for the ration $R_0 = |I'|/|I|$ and its "iterations" $R_i = |T_0^i(I')|/|T_0^i(I)|$. Denote

$$s_{n,m} = \left\{ \begin{array}{ll}
q_{n-m+1}, & \text{if } I \subset I_1^{n-m}, \\
q_{n-m}, & \text{if } I \subset I_1^{n-m+1}.
\end{array} \right.$$  

The following lemma will be used below.

**Lemma 2.6 ([8]).** There exists a constant $C = C(T_0) > 0$ and a natural number $N_0 = N_0(T_0)$ such that

$$\left| \ln \frac{R_i}{R_0} \right| \leq C \alpha_k^{-m}, \quad 0 < i < s_{n,m}$$

for all $n > N_0$.

3. Proof of Theorem 1.2

In this section we prove Theorem 1.2 i.e., we build the potential $U$ for $T_0$. Note that the proof of Theorem 1.2 follows closely that of Theorem 1.1 in [2]. To prove the theorem first we define the prelimit potentials $U^{(n)}_m(e_1, e_2, \ldots, e_m)$ and $U^{(n)}_m(e_1, e_2, \ldots, e_m)$ for $1 \leq m \leq n$ and then we show that these potentials converge to the same limit $U_m(e_1, e_2, \ldots, e_m)$ exponentially fast as $n \to \infty$. Finally we show that the limit of $U_m(e_1, e_2, \ldots, e_m)$ exists and unique as $m \to \infty$. Take $m \geq 1$ and fix it. Consider the $V_1^{(n-m)}$ neighborhood of $x_1$ for $n \geq m$. It is clear that $V_1^{(n-m)} \subset [y_0(0), x_3] \cup [x_2, \xi_0(0)]$ for $n \geq m + 4$. For definiteness we assume $(n - m)$-is even. The proof is similar for the case when $(n - m)$-is odd. It is obvious

$$I_1^{n-m} \subset [x_1, x_3] \quad \text{and} \quad I_1^{n-m+1} \subset [x_2, \xi(0)].$$
Consider two intervals $I' \in \mathbb{P}_n$ and $I \in \mathbb{P}_{n-1}$ such that $I' \subset I \subset I_1^{n-k}$. Let the words

$$I\left(\frac{a_1, 0, a_m, \ldots, 0, a, \varepsilon_m, \ldots, \varepsilon_2, \varepsilon_1}{a_1, 0, a_m, \ldots, 0, a, \varepsilon_m, \ldots, \varepsilon_2}\right)$$

be the symbolic representations of $I'$ and $I$ respectively. Define the following functions

$$U_m^{(n)}(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_m) = \ln \frac{I(a, 1, 0, a, \ldots, 0, a, \varepsilon_m, \ldots, \varepsilon_2, \varepsilon_1)}{I(a, 1, 0, a, \ldots, 0, a, \varepsilon_m, \ldots, \varepsilon_2)}.$$ 

and

$$\tilde{U}_m^{(n)}(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_m) = \ln \frac{I(1, 0, a, \ldots, 0, a, \varepsilon_m, \ldots, \varepsilon_2, \varepsilon_1)}{I(1, 0, a, \ldots, 0, a, \varepsilon_m, \ldots, \varepsilon_2)}.$$ 

It follows from the structure of dynamical partition and the definition of symbolical representation that

$$|I(1, 0, a, \ldots, 0, a, \varepsilon_m, \ldots, 0, a)| = |I(1, 0, a, \ldots, a, \varepsilon_m, \ldots, 0)|.$$ 

It is easy to see that

$$U_m^{(n)}(a, 0, \varepsilon_3, \ldots, \varepsilon_m) = \tilde{U}_m^{(n)}(a, 0, \varepsilon_3, \ldots, \varepsilon_m) = 0.$$ 

Using Theorem 2.5, we get:

$$I(a, 1, 0, a, \ldots, 0, a, \varepsilon_m, \ldots, \varepsilon_2, \varepsilon_1) = \eta_0(I(0, a, 0, a, \ldots, 0, a, \varepsilon_m, \ldots, \varepsilon_2, \varepsilon_1)) =$$

$$\eta_0(\alpha_k^{-(n-m-1)}(I(\varepsilon_m, \ldots, \varepsilon_2, \varepsilon_1)), \quad (3.1)$$

where $I(\varepsilon_m, \ldots, \varepsilon_2, \varepsilon_1) \in \mathbb{P}_m$. Similarly,

$$I(a, 1, 0, a, \ldots, 0, a, \varepsilon_m, \ldots, \varepsilon_2) = \eta_0(\alpha_k^{-(n-m-1)}(I(\varepsilon_m, \ldots, \varepsilon_2))) \quad (3.2)$$

where $I(\varepsilon_m, \ldots, \varepsilon_2) \in \mathbb{P}_{m-1}$. Denote by $(\beta_1, \beta_2)$ and $(\beta_3, \beta_4)$ the intervals that correspond to $I(\varepsilon_m, \ldots, \varepsilon_2, \varepsilon_1)$ and $I(\varepsilon_m, \ldots, \varepsilon_2)$, respectively. It is obvious that $(\beta_1, \beta_2) \subset (\beta_3, \beta_4)$. Using the definition $U_m^{(n)}$ and (3.1)-(3.2) we get

$$U_m^{(n)}(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_m) = \ln \left(\frac{|\eta_0(\alpha_k^{-(n-m-1)} \beta_2) - \eta_0(\alpha_k^{-(n-m-1)} \beta_1)|}{|\eta_0(\alpha_k^{-(n-m-1)} \beta_4) - \eta_0(\alpha_k^{-(n-m-1)} \beta_3)|}\right)$$

$$= \ln \left(\frac{|\beta_3 - \beta_4^3|}{|\beta_2 - \beta_3^3|} + O(\alpha_k^{-3(n-m)}) := U_m(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_m) + O(|\alpha_k|^{-3(n-m)}). \quad (3.3)$$

With the same manner one can show

$$\tilde{U}_m^{(n)}(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_m) = U_m(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_m) + O(|\alpha_k|^{-3(n-m)}). \quad (3.4)$$

Next we prove the existence of the limit of $U_m(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_m)$ when $m \to \infty$. For this we take a word $\varepsilon^m = (\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_m) \in \Omega_1$ and fix it. For a given $m$ consider the expression $U_m := U_m(\varepsilon_1, \ldots, \varepsilon_m)$. Using (3.3) and (3.4), one can get

$$U_{\ell+m} = \ln \frac{|I(\gamma_{2m}^m(\varepsilon_{\ell+m}), \varepsilon_{\ell+m}, \ldots, \varepsilon_1)|}{|I(\gamma_{2m}^m(\varepsilon_{\ell+m}), \varepsilon_{\ell+m}, \ldots, \varepsilon_2)|} + O(|\alpha_k|^{-6n}), \quad (3.5)$$
Theorem 1.2. Consider the intervals for sufficiently large \( \ell \) and range \( n \):

Combining (3.5), (3.7) and (3.8) we get

Substituting the right hand side of the above equation (3.10) we get

where \( \gamma_{2n}(\varepsilon_{\ell+m}) \) is a 2-dimensional vector of the form

and the interval \( \gamma_{2n}(\varepsilon_{\ell+m}, \varepsilon_{\ell+m-1}, \ldots, \varepsilon_1) \) is an element of dynamical partition \( P_{2n+\ell+m} \). It follows from the definition of symbolical dynamics, that the interval \( \gamma_{2n}(\varepsilon_{\ell+m}, \varepsilon_{\ell+m-1}, \ldots, \varepsilon_1) \) belongs to the trajectory of the interval \( I(\gamma_{2n}(\varepsilon_{\ell+m}, \varepsilon_{\ell+m-1}, \ldots, \varepsilon_1)) \). More precisely

where \( 0 \leq i < q_{2n+m} \) if \( \varepsilon_\ell = a \) and \( 0 \leq i < q_{2n+m+1} \) if \( \varepsilon_\ell = 0 \lor 1 \). Using (2.9), we get

On the other hand, by (3.3) and (3.4) we have

Combining (3.5), (3.7) and (3.8) we get

for sufficiently large \( \ell \) and \( m \). Hence \( (U_n)_n \) is a Cauchy sequence. Let \( U(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n, \ldots) \) be the limit function of the sequence \((U_n)_n\). Taking the limit in (3.9) as \( m \to \infty \), we get

This proves the first assertion of Theorem 1.2. Next we prove the second assertion of Theorem 1.2. Consider the intervals \( I(a_1, \ldots, a_n) \) and \( I(a_1, \ldots, a_r) \) such that \( I(a_1, \ldots, a_n) \subset I(a_1, \ldots, a_r) \subset [\eta_0(0), \eta_3] \cup [x_2, \xi_0(0)], \ r < n \). Denote by \( (\beta_1, \beta_{i+1}) \) and \( (d_i, d_{i+1}) \) the intervals that correspond to \( I(a_1, \ldots, a_{r+i}) \) and \( I(a_1, \ldots, a_{r+i-1}) \) respectively, where \( i \in [1, n-r] \). It is clear that \( (\beta_1, \beta_{i+1}) \subset (d_i, d_{i+1}) \). Using the same arguments as in (3.3), one can show that

Since \( [d_i, d_{i+1}] \subset [\eta_k(0), \eta_3] \cup [x_2, \xi_k(0)] \) and the rank of \( [d_i, d_{i+1}] \) is \( (r+i-1) \) we get

Substituting the right hand side of the above equation (3.10) we get

for sufficiently range \( n \). Taking the products from both sides of this relation over \( i = 1, (n-r) \), we obtain the second assertion of Theorem 1.2. Theorem 1.2 is completely proved.
4. Acknowledgements
The author would like to thank Professor A. A. Dzhalilov and Dr. H. Akhadkulov for making several useful suggestions which improved the text of the present paper. She also wishes to express her thanks to the referee for providing helpful comments. The paper is supported via the grant TWAS 14-121- RG/MATHS/AS...G-UNESCO FR: 324028604.
