We construct regular configurations of the Einstein-Yang-Mills theory in various dimensions. The gauge field is of meron-type: it is proportional to a pure gauge (with a suitable parameter $\lambda$ determined by the field equations). The corresponding smooth gauge transformation cannot be deformed continuously to the identity. In the three-dimensional case we consider the inclusion of a Chern-Simons term into the analysis, allowing $\lambda$ to be different from its usual value of $1/2$. In four dimensions, the gravitating meron is a smooth Euclidean wormhole interpolating between different vacua of the theory. In five and higher dimensions smooth meron-like configurations can also be constructed by considering warped products of the three-sphere and lower-dimensional Einstein manifolds. In all cases merons (which on flat spaces would be singular) become regular due to the coupling with general relativity. This effect is named “gravitational catalysis of merons”.

Keywords: Classical solutions to the Einstein-Yang-Mills equations, topological solutions in gravity, solitons in Yang-Mills theory, gravitationally coupled meron

I. INTRODUCTION

The existence of topological solitons is one of the most important non-perturbative effects in field theory\(^1\). These non-trivial topological objects are believed to play a fundamental role in the color confinement problem (for a detailed review, see \(^2\)) which is one of the “big” open issues in gauge field theory. A very important class of topological solitons is the Euclidean one (namely, regular solutions of the Euclidean theory). Euclidean topological solitons are especially relevant as they play a very important role at quantum level as non-trivial saddle points of the path integral. The most important Euclidean solutions are instantons (which are local regular minima of the Euclidean action) and sphalerons (which are saddle points with one-or a finite number of-unstable mode(s)). Unfortunately, analytic solutions are available only in special cases (in particular, when suitable BPS bounds can be saturated). In the case of instantons of Yang-Mills theory in 4 dimensions the saturation of the bound is equivalent to the self-duality condition. From the point of view of gravitational back-reaction, instantons are not very interesting as the self-duality condition implies that the energy-momentum tensor of the self-dual instanton vanishes so that it does not back-reacts on the metric at semi-classical level. From the Yang-Mills point of view, a very important type of Euclidean configurations are the so-called merons, firstly introduced in \(^3\). Merons are gauge fields interpolating between different topological sectors\(^1\). In particular, instantons can be interpreted as merons bound states\(^4\). It is commonly accepted that merons are quite relevant configurations from the point of view of the confinement problem (see, for instance, \(^2\)\(^6\)). In flat Euclidean spaces, merons are usually singular. Hence, on flat Euclidean spaces, a single “isolated”meron gives a vanishing contribution to the path integral as its Euclidean action is divergent. It is well known that merons are relevant only as “building blocks” of the instantons in the usual cases.

It is quite obvious that in many physically relevant situations the coupling with Einstein gravity\(^2\) cannot be neglected (this is the case for instance in early cosmology\(^8\) when topological solitons are believed to play a fundamental
role). Consequently, a very important question arises: Is it still true that merons are necessarily singular even when the coupling with General Relativity is taken into account? Indeed, due to the reasons mentioned above, whether or not merons are singular\(^3\) can have a big influence on our understanding of the confinement problem. A first hint that the coupling of merons with general relativity can change the “flat” picture quite considerably can be found (with Lorentzian signature) in \([9]\) \([10]\) where it has been shown that the singularity of the simplest meron can be hidden behind a black hole horizon.

A further very important situation where topological solitons play a fundamental role is in three Euclidean dimensions. The interest of the 3-dimensional case lies in the fact that difficult non-perturbative questions are easier to understand in three-dimensional Yang–Mills theory than in the four dimensions. Despite being simpler than QCD, three-dimensional Yang-Mills theory possesses local interacting degrees of freedom. A further benefit of three-dimensional Yang–Mills theory is that it is a good approximation of high temperature QCD\(^4\). Last but not least, the Chern–Simons term can be included \([11, 12]\), leading to a mass for the gauge field which is of topological origin. The inclusion of the Chern-Simons term is not only a nice theoretical exercise since it can be shown that such a term appears upon integrating out the fermions (see, for instance \([13]\) and \([14]\); a detailed review is \([15]\)). Moreover, the non-perturbative features of topologically massive Yang-Mills theory in three dimensions are in a very good agreement with the expected confinement picture \([16]\).

Very deep open issues related to three-dimensional topologically massive Yang-Mills theory are related to the following fact. Such a theory in a suitable range of parameters (see \([16]\)) is confining. Standard arguments (see \([2]\)) suggest that regular non-trivial Euclidean saddle points of the path integral must play a fundamental role to understand confinement. However, in three Euclidean dimensions, it is not possible to construct the usual self-dual Yang-Mills instantons (since one would need the four-dimensional Levi-Civita \(\epsilon\)-symbol). In fact, as it will be discussed in the next sections, although there are no self-dual instantons in three Euclidean dimensions one can still construct regular smooth gravitating merons.

In general, it is very difficult to analyze the gravitational properties of topologically non-trivial configurations. Due to the difficulties in constructing analytic regular configurations of the four-dimensional Einstein-Yang-Mills system many of the available results are numerical (see, for instance, \([17–21]\)).

The first aim of the present paper is to show that, nevertheless, it is possible to construct analytic regular solutions corresponding to gravitating merons in various dimensions in Euclidean Einstein-Yang-Mills theory. In order to achieve this goal two techniques are combined. The first technique is based on the \(SU(2)\)-valued generalized hedgehog ansatz (introduced in \([22–37]\)), which works both for the Skyrme model and for the Yang-Mills-Higgs system. The second is based on the Cho approach \([38–42]\).

The second aim is to show the coupling with Einstein gravity can change quite dramatically the usual physical interpretation of merons. In the three-dimensional case, we construct regular gravitating meron-like configurations and include a Chern-Simons term into the analysis. Due to the fact that in three dimensions it is not possible to define self-dual configurations, the regular Euclidean saddle points constructed here are likely to play a fundamental role to understand the non-perturbative features of the theory. In the four-dimensional case, we construct different regular gravitating meron-like configurations. Such configurations can be seen as smooth Euclidean wormholes interpolating between different vacua of the theory. Euclidean wormholes \([43, 55]\) (see, for a recent view on this topic, \([56]\)) can be defined as extrema of the action in Euclidean quantum gravity connecting distant regions. It is widely recognized that such configurations can have quite remarkable physical consequences (as discussed in details in the above references). In five dimensions dimensions we construct regular meron-like configurations that generalize the three-dimensional result previously found for \(\lambda = 1/2\). The metric is given by the a two-dimensional constant curvature space times the three-sphere. This result can be further extended to arbitrary higher dimensions. In dimension \(D > 6\) the metric turns out to be given by the warped product of the three-sphere and any solution of the \(D - 3\)-dimensional Einstein equations in vacuum with an effective cosmological constant.

This paper is organized as follows: in the second section, meron-like configurations within the Euclidean Einstein-Yang-Mills theory are introduced. In the third section, we present a general ansatz to construct merons and Einstein-Yang-Mills equations are discussed. In the fourth section the solutions are constructed. First, three-dimensional smooth regular gravitating merons are considered, the effects of the Chern-Simons term are included and the corresponding Euclidean action is computed. In four-dimensional case, smooth and regular gravitating merons are presented.

\(^3\) Hence, whether or not merons can give a finite contribution to the semi-classical path integral through the corresponding saddle points.

\(^4\) In which case the mass gap plays the role of the magnetic mass.
and their interpretation as Euclidean wormholes is discussed. Finally, we construct regular meron-like configurations in five and higher dimensions. In the fifth section, some conclusions are drawn.

II. THE SYSTEM

We consider the Euclidean Einstein-Yang-Mills system in $D$ dimensions with cosmological constant. The action of the system is

$$S = S_G + S_{SU(2)},$$

where the gravitational action $S_G$ and the gauge field action $S_{SU(2)}$ are given by

$$S_G = -\frac{1}{16\pi G} \int d^D x \sqrt{g} (R - 2\Lambda),$$

$$S_{SU(2)} = -\frac{1}{8e^2} \int d^D x \sqrt{g} \text{Tr} (F_{\mu\nu} F^{\mu\nu}).$$

where $R$ is the Ricci scalar, $G$ is Newton’s constant, $\Lambda$ is the cosmological constant, $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu + [A_\mu, A_\nu]$ is the field strength associated to the gauge field $A_\mu$ and $e$ is the Yang-Mills coupling constant. In our conventions $c = \hbar = 1$. The resulting $N$-dimensional Einstein equations are

$$G_{\mu\nu} + \Lambda g_{\mu\nu} = 8\pi GT_{\mu\nu},$$

where $G_{\mu\nu}$ is the Einstein tensor and $T_{\mu\nu}$ is the stress-energy tensor of the Yang-Mills field

$$T_{\mu\nu} = \frac{2}{\sqrt{g}} \frac{\delta S_{SU(2)}}{\delta g^{\mu\nu}} = -\frac{1}{2e^2} \text{Tr} \left( F_{\mu\alpha} F_{\nu\beta} g^{\alpha\beta} - \frac{1}{4} g_{\mu\nu} F^{\rho\sigma} F_{\rho\sigma} \right).$$

The Yang-Mills equations are given by

$$Y M^\mu = \nabla_\nu F^{\mu\nu} + [A_\nu, F^{\mu\nu}] = 0,$$

where $\nabla^\mu$ is the Levi-Civita covariant derivative. The connection $A_\mu = A_\mu^A t_A$ takes values on the $SU(2)$ algebra, whose generators are defined as

$$t_A = i\sigma_A, \quad A = 1, 2, 3,$$

$\sigma_A$ being the Pauli matrices.

Meron-like configurations as well as their important role in the non-perturbative sector of Yang-Mills theory have been extensively discussed in the literature (see, for instance, [3–7]). All the most important examples can be written in the following form\textsuperscript{5}

$$A_\mu = \lambda U^{-1} \partial_\mu U, \quad \lambda \neq 0, 1.$$

As it will be shown in the following, the Yang-Mills equations fix the parameter $\lambda$. Therefore, our definition of meron in the present paper will be a regular configuration of the form in Eq. (8) constructed with a topologically non-trivial $SU(2)$ map $U(x^\mu)$. Note that the definition of meron in Eq. (8) works both with Euclidean and with Lorentzian signature. Although we will focus in this work mainly on the Euclidean case, many of the present results can be easily extended to the Lorentzian case.

We adopt the standard parametrization of the $SU(2)$-valued scalar $U(x^\mu)$

$$U^{\pm 1}(x^\mu) = Y^0(x^\mu) I \pm Y^A(x^\mu) t_A, \quad (Y^0)^2 + Y^A Y_A = 1,$$

\textsuperscript{5} It is more common to use the ’t Hooft symbol (which is a Levi-Civita $\varepsilon$-tensor in which some of the indices are internal while others are space-time indices). On flat spaces, the usual notation is equivalent to the one in Eq. (8). On curved spaces the notation in Eq. (8) is much more convenient as it avoids the problem to properly define the ’t Hooft symbol on curved spaces.
where \( \mathbf{I} \) is the \( 2 \times 2 \) identity. The last equality implies that \((Y^0, Y^A)\) is a unit vector in a three sphere, which is naturally accounted for by writing

\[
Y^0 = \cos \alpha, \quad Y^A = n^A \cdot \sin \alpha,
\]

\[
n^1 = \sin \Theta \cos \Phi, \quad n^2 = \sin \Theta \sin \Phi, \quad n^3 = \cos \Theta.
\]  

(10)

As it will be explained in the next sections, the ansatz for the \( \alpha, \Theta \) and \( \Phi \) functions will be chosen in order to have a non-vanishing winding number.

### III. ANSATZ

For our purposes it will be convenient to introduce the left-invariant Maurer-Cartan forms on \( SU(2) \), which can be defined in terms of the Euler angles \( x^i = (\psi, \theta, \varphi) \) by

\[
\Gamma_1 = \frac{1}{2} (\sin \psi d\theta - \sin \theta \cos \psi d\varphi),
\]

\[
\Gamma_2 = \frac{1}{2} (\cos \psi d\theta - \sin \theta \sin \psi d\varphi),
\]

\[
\Gamma_3 = \frac{1}{2} (d\psi + \cos \theta d\varphi),
\]

\[
0 \leq \psi < 4\pi, \quad 0 \leq \theta < \pi, \quad 0 \leq \varphi < 2\pi.
\]

We will consider a \( D \)-dimensional euclidean space-time of the form

\[
ds^2 = g_{\mu\nu} dx^\mu dx^\nu = \gamma_{ab}(z) dz^a dz^b + \rho(z)^2 \sum_{i=1}^{3} \Gamma_i \otimes \Gamma_i,
\]  

(11)

where we have split the coordinates as \( x^\mu = (z^a, x^i) \), \( a = 1, \ldots, d = D - 3 \), \( \gamma_{ab} \) is a \( d \)- dimensional metric and \( \rho(z) \) is a warping factor depending on the coordinates \( z^a \) only.

As it has been discussed in [30], [36], [37], the following choice for the functions in (10) is suitable for the class of metrics (11):

\[
\Phi = \frac{\psi + \varphi}{2}, \quad \tan \Theta = \frac{\cot \left( \frac{\theta}{2} \right)}{\cos \left( \frac{\psi + \varphi}{2} \right)}, \quad \tan \alpha = \sqrt{1 + \tan^2 \Theta} \tan \left( \frac{\psi + \varphi}{2} \right).
\]  

(12)

It is easy to verify directly that in any background metric of the form in Eq. (11), a meron ansatz of the form in Eqs. (8), (10) and (12) identically satisfies the Lorentz gauge condition (something which simplifies considerably the Yang-Mills equation):

\[
\nabla^\mu A_\mu = 0.
\]  

(13)

It is also worth to emphasize that the present ansatz is topologically non-trivial as it has a non-trivial winding number along the \( z^a = \text{const} \) hypersurfaces of the metric in Eq. (11):

\[
W = -\frac{1}{24\pi^2} \int_{S^3} tr \left( (U^{-1} dU)^3 \right) = -\frac{1}{2\pi^2} \int \sin^2 \alpha \sin \Theta d\alpha d\Theta d\Phi = 1.
\]  

(14)

Hence, the present configuration cannot be deformed continuously to the trivial vacuum.
A. Yang-Mills equations

In the coordinates $x^\mu = (z^a, x^i)$, the gauge potential is split in two parts $A_\mu = \{A_a, A_i\}$. The ansatz in Eqs. (8), (10) and (12) leads to the following form for $A_i$

\[
A_\varphi = -\frac{\lambda}{2} \left( \sin \theta \cos \varphi t_1 + \sin \theta \sin \varphi t_2 - \cos \theta t_3 \right), \\
A_\theta = \frac{\lambda}{2} \left( \sin \varphi t_1 - \cos \varphi t_2 \right), \\
A_\varphi = \frac{\lambda}{2} t_3,
\]

while the components $A_a$ identically vanish

\[A_a = 0.\]

As the connection is time independent, the non-Abelian “electric” field vanishes and this meron-like configuration is purely “magnetic”. In fact, the non-vanishing space-time components of the field strength are

\[
F_{\psi\theta} = -\frac{\lambda(\lambda - 1)}{2} \left( \cos \theta \cos \varphi t_1 + \cos \theta \sin \varphi t_2 + \sin \theta t_3 \right), \\
F_{\psi\varphi} = \frac{\lambda(\lambda - 1)}{2} \sin \theta \left( \sin \varphi t_1 - \cos \varphi t_2 \right), \\
F_{\theta\varphi} = \frac{\lambda(\lambda - 1)}{2} \left( \cos \varphi t_1 + \sin \varphi t_2 \right),
\]

and the left hand sides of Yang-Mills equations (6) become,

\[
YM^\psi = \frac{8\lambda(\lambda - 1)}{\rho^4 \sin \theta} \left( 2\lambda - 1 \right) (\cos \varphi t_1 + \sin \varphi t_2), \\
YM^\theta = \frac{8\lambda(\lambda - 1)}{\rho^4} \left( 2\lambda - 1 \right) (-\sin \varphi t_1 + \cos \varphi t_2), \\
YM^\varphi = -\frac{8\lambda(\lambda - 1)}{\rho^4 \sin \theta} \left( \sin \theta \cos \varphi t_1 + \sin \theta \sin \varphi t_2 + \sin \theta t_3 \right), \\
YM^a = 0.
\]

Therefore, the Yang-Mills equations are identically satisfied for

\[
\lambda = \frac{1}{2}.
\]

This is the standard value of $\lambda$ for meronic configurations (8). As we will show, in three-dimensions it is possible to find a different result for $\lambda$ when a Chern-Simons term is included in the action for the SU(2) gauge field. For $D > 3$ however, $\lambda = \frac{1}{2}$ will be assumed.

B. Einstein equations

In (11), the metric $g_{\mu\nu}$ splits as $g_{ij} = \rho(z)^2 h_{ij}(x)$, $g_{ab} = \gamma_{ab}(z)$, $g_{ia} = 0$, where $h_{ij}$ is the metric of the three sphere in the coordinates $x^i$,

\[
\sum_{i=1}^{3} \Gamma_i \otimes \Gamma_i = h_{ij} dx^i dx^j = \frac{1}{4} \left( d\psi^2 + 2 \cos \theta d\psi d\varphi + d\theta^2 + d\varphi^2 \right).
\]

The Ricci tensor and the Ricci scalar are then given by

\[
R_{ij} = 2 h_{ij} \left( 1 - \nabla_a \rho \nabla^a \rho - \frac{1}{2} \rho \nabla^2 \rho \right), \\
R_{ia} = 0, \\
R_{ab} = \tilde{R}_{ab} - \frac{3}{\rho} \nabla_b \nabla_a \rho, \\
R = \tilde{R} + \frac{6}{\rho^2} \left( 1 - \nabla_a \rho \nabla^a \rho - \rho \nabla^2 \rho \right).
\]
where $\tilde{R}_{ab}$, $\tilde{R}$ and $\tilde{\nabla}$ denote the Ricci tensor, the Ricci scalar and the covariant derivative associated to the metric $\gamma_{ab}$ respectively. Therefore, the Einstein tensor takes the form

$$G_{ij} = h_{ij} \left( \tilde{\nabla}_a \rho \tilde{\nabla}^a \rho + 2 \rho \tilde{\nabla}^2 \rho - \frac{\rho^2}{2} \tilde{R} - 1 \right),$$

$$G_{ia} = 0,$$

$$G_{ab} = R_{ab} - \frac{1}{2} \gamma_{ab} \tilde{R} + \frac{3}{\rho^2} \left[ \gamma_{ab} \left( \tilde{\nabla}_c \rho \tilde{\nabla}^c \rho + \rho \tilde{\nabla}^2 \rho - 1 \right) - \rho \tilde{\nabla}_b \tilde{\nabla}_a \rho \right].$$

(20)

The stress-energy tensor (5) for the meron field is given by

$$T_{ij} = \frac{2 \lambda^2 (\lambda - 1)^2}{e^2 \rho^2} h_{ij},$$

$$T_{ia} = 0,$$

$$T_{ab} = - \frac{6 \lambda^2 (\lambda - 1)^2}{e^2 \rho^4} \gamma_{ab},$$

(21)

and therefore Einstein equations (4) yield

$$\tilde{\nabla}_a \rho \tilde{\nabla}^a \rho + 2 \rho \tilde{\nabla}^2 \rho - \frac{\rho^2}{2} \tilde{R} + \Lambda \rho^2 - 1 = \frac{16 \pi G}{e^2 \rho^2} \lambda^2 (\lambda - 1)^2,$$

(22)

$$\frac{\rho^2}{3} \tilde{G}_{ab} + \gamma_{ab} \left( \tilde{\nabla}_c \rho \tilde{\nabla}^c \rho + \rho \tilde{\nabla}^2 \rho - \frac{\Lambda \rho^2}{3} - 1 \right) - \rho \tilde{\nabla}_b \tilde{\nabla}_a \rho = - \frac{16 \pi G}{e^2 \rho^2} \lambda^2 (\lambda - 1)^2 \gamma_{ab}.$$  

(23)

where we have defined $\tilde{G}_{ab} = R_{ab} - \frac{1}{2} \gamma_{ab} \tilde{R}$ as the Einstein tensor associated to the metric $\gamma_{ab}$. Notice that the $(i,j)$ components of the field equations reduce into a single equation (22). It should be emphasized that the same reduction of the $(i,j)$ components of the field equations hold even with the Gauss-Bonnet term on the left hand side of the field equations, which is given by

$$H_{\mu\nu} = 2 (RR_{\mu\nu} - 2 R_{\mu\rho} R^\rho_{\nu} - 2 R^{\sigma\tau} R_{\mu\rho\sigma\tau} + R_{\mu}^{\rho\alpha\beta} R_{\nu\rho\alpha\beta}) - \frac{1}{2} g_{\mu\nu} \left( R^2 - 4 R_{\alpha\beta} R^{\alpha\beta} + R_{\alpha\beta\gamma\delta} R^{\alpha\beta\gamma\delta} \right).$$  

(24)

This can be easily shown by observing the following equations

$$R_{ijklm} = \rho^2 \left( 1 - \tilde{\nabla}_a \rho \tilde{\nabla}^a \rho \right) \left( h_{ik} h_{jm} - h_{im} h_{jk} \right),$$

(25)

$$R_{ijab} = R_{ibac} = R_{aijk} = 0,$$

(26)

$$R_{iajb} = - \rho \ h_{ij} \tilde{\nabla}_a \rho,$$

(27)

from which one has $H_{ia} = 0$, and $H_{ij} \propto h_{ij}$. To solve the Einstein-Yang-Mills equations for meron configurations with the Gauss-Bonnet term is a valuable task in its own right. In this paper, however, we focus only on the Einstein-Hilbert action for the gravity sector, and the issues related to the Gauss-Bonnet gravity will be studied in a separate paper.

IV. SOLUTIONS

A. $D = 3$

In three dimensions $\gamma_{ab} = 0$ and and $\rho = \rho_0$ is constant. Therefore the metric (11) is simply given by

$$ds^2 = \rho_0^2 \sum_{i=1}^{3} \Gamma_i \otimes \Gamma_i = \frac{\rho_0^2}{4} \left( d\tau^2 + 2 \cos \theta d\tau d\phi + d\theta^2 + d\phi^2 \right),$$

(28)

where we have considered $\psi = \tau$ as the euclidean time. In this case, Einstein equations (22) yield one single algebraic equation for $\rho_0$,

$$\Lambda \rho_0^2 - 1 = \frac{16 \pi G}{e^2 \rho_0^2} \lambda^2 (\lambda - 1)^2,$$

(29)
which can be solved for \( \Lambda > 0 \). As Yang-Mills equations \(^{17}\) require \( \lambda = 1/2 \), equation \(^{29}\) fixes \( \rho_0 \) to be

\[
\rho_0^2 = \frac{1}{2\lambda} \left( 1 \pm \sqrt{1 + \frac{4\pi G \Lambda}{e^2}} \right).
\]

(30)
The meronic configuration in this case is defined on the three-sphere with overall factor \( \rho_0 \) and it is regular and smooth everywhere.

**Chern-Simons term**

In the three-dimensional case it is possible to find a more general meron-like solution by adding a Chern-Simons term to the action \(^{3}\) and considering

\[
S_{SU(2)} = -\frac{1}{8e^2} \int d^D x \sqrt{g} \text{Tr}(F^{\mu\nu} F_{\mu\nu}) + S_{CS},
\]

where the Chern-Simons action for the \( SU(2) \) valued gauge field is given by

\[
S_{CS} = \frac{k}{2e^2} \int \text{Tr} \left[ A dA + \frac{2}{3} A^3 \right],
\]

(31)

and \( k \) is related to the Chern-Simons level\(^{6}\). This modification leads to the Yang-Mills-Chern-Simons equations

\[
\text{YMCS}^\mu = \nabla_\nu F^{\mu\nu} + [A_\nu, F^{\mu\nu}] + k \epsilon_\nu^{\rho\sigma} F_{\rho\sigma} = 0.
\]

(32)

Using \(^{17}\) and \(^{10}\) it is straightforward to check that

\[
\begin{align*}
\text{YMCS}^\psi &= \frac{8\lambda(\lambda - 1)}{\rho^2 \sin \theta} \left( 2\lambda - 1 + k\rho_0 \right) \left( \cos \varphi t_1 + \sin \varphi t_2 \right), \\
\text{YMCS}^\theta &= \frac{8\lambda(\lambda - 1)}{\rho^2 \sin \theta} \left( 2\lambda - 1 + k\rho_0 \right) \left( -\sin \varphi t_1 + \cos \varphi t_2 \right), \\
\text{YMCS}^\phi &= -\frac{8\lambda(\lambda - 1) (2\lambda - 1 + k\rho_0)}{\rho^2 \sin \theta} \left( \cos \theta \cos \varphi t_1 + \cos \theta \sin \varphi t_2 + \sin \theta t_3 \right),
\end{align*}
\]

(33)

which leads to

\[
\lambda = \frac{1}{2} \left( 1 - k\rho_0 \right)
\]

(34)

(note that in the Einstein-Yang-Mills case \( k = 0 \) we get the usual “meronic” value \( \lambda = 1/2 \)).

Due to its topological nature, the Chern-Simons term does not contribute to the energy-momentum tensor \(^{21}\). This means that, when \(^{31}\) is included in the gauge field action, the only modification in the Einstein equations \(^{29}\) is the value of \( \lambda \). In this case we obtain

\[
\rho_0^2 \Lambda - 1 = \frac{\pi G}{e^2 \rho_0^2} (1 - k^2 \rho_0^2)^2,
\]

(35)

which can be solved for \( \Lambda > 0 \) to give

\[
\rho_0^2 = \frac{e^2 - 2\pi G k^2 \pm \sqrt{e^2 + 4\pi G (\Lambda - k^2)}}{2e^2 \Lambda - 2\pi G k^4}.
\]

(36)

Note that for \( \rho_0^2 \) to be positive, one of the following conditions must hold:

(i) \( e^2 + 4\pi G (\Lambda - k^2) > 0 \), \( 2\pi G k^2 > e^2 \), \( e^2 \Lambda < \pi G k^4 \),

(ii) \( e^2 \Lambda > \pi G k^4 \),

(iii) \( e^2 + 4\pi G (\Lambda - k^2) = 0 \), \( (e^2 - 2\pi G k^2)(e^2 \Lambda - \pi G k^4) > 0 \),

(iv) \( e^2 \Lambda = \pi G k^4 \), \( k^2 / \Lambda < 2 \).

\(^6\) There are two possible conventions for the Chern-Simons level \( k \): we will comment on them in the following sections.
Imaginary coupling

In order for the theory to have a well-defined Lorentzian continuation, the Euclidean Chern-Simons term must have imaginary coupling \((k \rightarrow ik, k \in \mathbb{N}, i^2 = -1)\). In this case the solutions look very similar with the difference that the meron parameter \(\lambda\) is not real anymore, :

\[
\lambda = \frac{1}{2}(1 - ikR_0), \quad R_0 \in \mathbb{R}.
\]

These configurations represent complex saddle points of the Einstein-Yang-Mills-Chern-Simons action. In recent years, it has been shown in many non-trivial examples (see \([57]\) and references therein; for detailed reviews see \([58–60]\)) that non-trivial complex saddle points are necessary to give a consistent non-perturbative definition of the path integral. In particular, when such complex saddles are not included in the analysis, inconsistencies appear. Hence, the present results strongly suggest that these gravitating merons are relevant building blocks to get a consistent path-integral in the Einstein-Yang-Mills-Chern-Simons case.

Euclidean action

Also in the three-dimensional case the non-perturbative nature of this configurations is apparent as they depend on \(1/e^2\). In particular, the classical Euclidean action \(I_E\) corresponding to the set of solutions can be easily computed to give:

\[
I_E = h \left( \frac{1}{e^2}, \Lambda, G, k \right) = \frac{\pi \rho_0}{4G} \left( \rho_0^2 \Lambda - 3 \right) + \frac{12\pi^2}{e^2 \rho_0} \lambda^2 (\lambda - 1)^2 - \frac{4\pi^2 k}{e^2} \lambda^2 (\lambda + 3).
\]

The obvious relevance of this result is that, at semi-classical level, the contribution of this configuration to the path-integral is proportional to \(Z_E\),

\[
Z_E \approx \exp \left[ -I_E \right].
\]

Therefore, gravitating merons play an important role in the non-perturbative sector of the theory. This is especially important in the three-dimensional case in which self-dual instantons do not exist and, consequently, these Euclidean smooth regular (and with finite actions) configurations can be quite relevant.

It is also worth to emphasize the remarkable effect of the Chern-Simons term which supports the existence of gravitating merons with \(\lambda \neq 1/2\). To the best of authors knowledge, these are the first examples of smooth merons with this characteristic. Due to the fact that the Chern-Simons term can arise upon integrating over Fermionic degrees of freedom, it is natural to wonder whether one could construct merons with \(\lambda \neq 1/2\) even with Fermionic matter fields. We hope to come back on this very interesting question in a future publication. As it has been already emphasized, in the case in which the Chern-Simons coupling is taken as \(ik\) with \(k \in \mathbb{R}\), the present configurations have to be considered as smooth regular complex saddle points. Correspondingly, the Euclidean action also gets a non-trivial imaginary part. These configurations have to be properly analyzed using resurgence techniques (following \([57–60]\)). We hope to come back on this issue in a future publication.

As far as the evaluation of the Euclidean action of the four dimensional solutions is concerned, it involves some subtleties. The reason is that, in the presence of a negative cosmological constant, one needs to include suitable boundary terms to obtain a finite results. The construction of these boundary terms when topologically non-trivial non-Abelian gauge fields are present has not been discussed in details in the literature. We hope to come back on this interesting issue in a future publication.

B. \(D = 4\)

In four dimension we consider only one extra coordinate \(z = r\) in \([11]\) and for simplicity we will just take \(\gamma_{rr} = 1\). The metric then takes the form

\[
ds^2 = dr^2 + \rho^2 (r) \left( d\tau^2 + 2 \cos \theta d\tau d\varphi + d\theta^2 + d\varphi^2 \right).
\]

(39)
where again we have considered $\psi = \tau$ as the euclidean time. Einstein equations (22) and (23) are reduced to two ordinary differential equations

\[
\rho'^2 + 2\rho\rho'' + \Lambda \rho^2 - 1 = \frac{\pi G}{e^2 \rho^2}, \tag{40}
\]

\[
\rho'^2 + \frac{\Lambda}{3} \rho^2 - 1 = -\frac{\pi G}{e^2 \rho^2}, \tag{41}
\]

where we have already replaced (18). If we plug the equation (41) into (40), then we have a single ODE of $\rho(r)$,

\[
\rho\rho'' + \frac{\Lambda}{3} \rho^2 - \frac{\pi G}{e^2 \rho^2} = 0. \tag{42}
\]

When the cosmological constant $\Lambda$ is positive, there does not exist real solution to this equation. Now let us examine the cases of zero and negative cosmological constants. Similar results have been discussed in [43–47].

**Case 1: $\Lambda = 0$**

When $\Lambda = 0$, the solution to (42) is,

\[
\rho(r) = \frac{1}{e} \sqrt{a(r + b)^2 + \frac{\pi Ge^2}{a}}, \tag{43}
\]

where $a$ and $b$ are integration constants. This solution satisfies the equations (40) and (41) if

\[
a = e^2.
\]

Thus the solution for vanishing cosmological constant is,

\[
\rho(r) = \sqrt{\frac{\pi G}{e^2} + (r + b)^2}. \tag{44}
\]

Hence, these configurations can be interpreted as smooth asymptotically flat Euclidean wormholes sourced by merons. The size of the throat is proportional to $1/e^2$ thus showing explicitly that the “opening of the throat” is a non-perturbative phenomenon. Moreover, the fact that such Euclidean wormholes are sourced by Yang-Mills merons (which, by themselves, represent tunneling between different Gribov vacua [7]) sheds considerable light on the physical interpretation of these Euclidean wormholes. Indeed, the solution is smooth and regular everywhere, the gauge field is regular and the scale factor $\rho$ is smooth and non-vanishing. In particular, both asymptotic regions (corresponding to $r \to \pm \infty$) are flat (the wormhole throat being at $r = -b$). Similar Euclidean wormhole solutions have been studied in [43–46]. Examples of Euclidean wormholes embedded in higher dimensional theories as well as including the explicit presence of axionic fields have been worked out in [48–56].

**Case 2: $\Lambda < 0$**

When $\Lambda < 0$, the solution to (42) is,

\[
\rho(r) = \frac{1}{4e} \left[ 2C_1 \left( \frac{64\pi Ge^2}{C_1} + C_2 \right) \exp \left( 2\sqrt{-\frac{\Lambda}{3}} r \right) - \frac{3}{4A} \exp \left( -2\sqrt{-\frac{\Lambda}{3}} r \right) + \frac{3}{A\sqrt{-\frac{A}{3}}} C_2 \right]^{1/2}, \tag{45}
\]

where $C_1$ and $C_2$ are integration constants. The above solution is real whenever $C_1$ is positive. In addition, this solution satisfies the equations (40) and (41) if $C_1$ and $C_2$ are related by

\[
C_1 C_2 = -4e^2 \sqrt{3\frac{3}{-\Lambda}}.
\]
With these conditions, we have the solution $\rho(r)$ given by,

$$
\rho(r) = \frac{1}{4e} \left[ \frac{2}{C_1} \left( 64\pi Ge^2 - \frac{48e^4}{\Lambda} \right) \exp \left( 2\sqrt{-\frac{\Lambda}{3}} r \right) - \frac{3C_1}{2\Lambda} \exp \left( -2\sqrt{-\frac{\Lambda}{3}} r \right) + 24e^2 \right]^{1/2}.
$$

Let us notice that the argument of the square root is positive definite, and its minimum value

$$
\rho_{\text{min}} = \frac{\sqrt{6}}{2\sqrt{-\Lambda}} \left[ \sqrt{1 - \frac{4\pi GA}{3e^2}} - 1 \right]^{1/2}
$$

occurs at

$$
r = \frac{1}{2\sqrt{-\Lambda}} \log \left( \frac{\sqrt{3}C_1}{8e\sqrt{3e^2 - 4\pi GA}} \right),
$$

if the right hand side of (48) is positive. Therefore, if we choose a sufficiently small positive constant $C_1$, then the corresponding solution is regular and smooth everywhere for any $r \in \mathbb{R}$.

In these cases both asymptotic regions (namely, $r \to \pm \infty$) are (the Euclidean version of) AdS.

Thus, both in Case 1 and in Case 2 described above the gravitating merons can be interpreted as smooth Euclidean wormholes interpolating between the vacua of the theory. It is also worth to emphasize that also in this case the (size of the) wormhole throat is non-perturbative in the Yang-Mills coupling $e^2$ (as it depends on $1/e^2$; see Eqs. (44) and (47)). Consequently, the present configurations will be relevant in the non-perturbative sector of Einstein-Yang-Mills theory.

C. $D = 5$

Solutions with constant $\rho$ analogous to the three-dimensional one previously constructed cannot be generalized to four dimensions, as in that case the equations (22) and (23) do not admit solutions for constant $\rho$. For $D > 4$, however, the warping factor $\rho$ can be taken as a constant $\rho_0$. In five dimensions we can consider coordinates $z^a = (\tau, r)$, were $\tau$ is the Euclidean time and $r$ a radial coordinate. The simplest solutions of the form (11) can be obtained by considering a two-dimensional metric $\gamma_{ab}$ with constant curvature $\tilde{R} = K$ and

$$
\gamma_{ab} = \begin{pmatrix}
 r^2 & 0 \\
 0 & \frac{1}{1 + \frac{\pi G}{e^2 \rho_0^2}}
\end{pmatrix}.
$$

In that case, Einstein equations (22) and (23) take the form

$$
\left( K - \frac{\Lambda}{2} \right) \rho_0^2 + 1 + \frac{\pi G}{e^2 \rho_0^2} = 0,
$$

$$
\frac{\Lambda \rho_0^2}{3} - 1 + \frac{\pi G}{e^2 \rho_0^2} = 0.
$$

Eq. (49) fixes $K$ in terms of $\rho_0$, $\Lambda$, $G$ and $e$,

$$
K = 2\Lambda - \frac{2}{\rho_0^2} \left( 1 + \frac{\pi G}{e^2 \rho_0^2} \right),
$$

while Eq. (50) determines $\rho_0^2$.

- For $\Lambda > 0$ and $\frac{4\pi GA}{3e^2} \leq 1$,

$$
\rho_0^2 = \frac{3}{2\Lambda} \left[ 1 \pm \sqrt{1 - \frac{4\pi GA}{3e^2}} \right].
$$
• For $\Lambda = 0$,

$$\rho_0^2 = \frac{\pi G}{e^2}. \quad (52)$$

• For $\Lambda < 0$,

$$\rho_0^2 = \frac{3}{2\Lambda} \left[ 1 - \sqrt{1 - \frac{4\pi G \Lambda}{3e^2}} \right]. \quad (53)$$

As in the three-dimensional case, one could be tempted to add a five-dimensional Chern-Simons term to the Yang-Mills actions (3). However the five-dimensional Chern-Simons equations are proportional to $\epsilon^{\mu\nu\rho\sigma\lambda} F_{\mu\nu} F_{\rho\sigma\lambda}$ which vanishes for the the meron field-strength (10). The same argument holds in higher odd-dimensional cases.

### D. Higher dimensions

Solutions of the form (51) can be easily extended to arbitrarily higher dimensions. In fact, for $\rho = \rho_0$ a constant, and $\gamma_{ab}$ a $d$-dimensional metric. Einstein equations (22) and (23) reduce in general to

$$\left( \frac{\tilde{R}}{2} - \Lambda \right) \rho_0^2 + 1 + \frac{\pi G}{e^2 \rho_0^2} = 0, \quad (54)$$

$$\tilde{G}_{ab} + \left[ \Lambda + \frac{3}{\rho_0^2} \left( \frac{\pi G}{e^2 \rho_0^2} - 1 \right) \right] \gamma_{ab} = 0. \quad (55)$$

The first equation implies that the Ricci tensor $\tilde{R}$ for the metric $\gamma_{ab}$ is constant, while the second equation can be written as the Einstein equations for $\gamma_{ab}$ with an effective cosmological constant:

$$\tilde{\Lambda} = \Lambda + \frac{3}{\rho_0^2} \left( \frac{\pi G}{e^2 \rho_0^2} - 1 \right).$$

This means that in any dimension $D = d + 3$ with $d > 2$, the metric $\gamma_{ab}$ is an Einstein manifold with cosmological constant $\tilde{\Lambda}$, i.e,

$$\tilde{R}_{ab} = \frac{2\tilde{\Lambda}}{d - 2} \gamma_{ab},$$

which means that the Ricci scalar $\tilde{R}$ is given by

$$\tilde{R} = \frac{2d}{d - 2} \left[ \Lambda + \frac{3}{\rho_0^2} \left( \frac{\pi G}{e^2 \rho_0^2} - 1 \right) \right].$$

Plugging this back in Eq. (54) we find $\rho_0^2$ to be:

• For $\Lambda > 0$ and $\frac{4\pi G \Lambda (2d - 1)}{e^2 (d + 1)^2} \leq 1$,

$$\rho_0^2 = \frac{d + 1}{2\Lambda} \left[ 1 \pm \sqrt{1 - \frac{4\pi G \Lambda (2d - 1)}{e^2 (d + 1)^2}} \right]. \quad (56)$$

• For $\Lambda = 0$, 

\[ \rho_0^2 = \frac{\pi G(2d-1)}{e^2(d+1)}. \quad (57) \]

- For \( \Lambda < 0 \),

\[ \rho_0^2 = \frac{d + 1}{2\Lambda} \left[ 1 \pm \sqrt{1 - \frac{4\pi G\Lambda(2d-1)}{e^2(d+1)^2}} \right]. \quad (58) \]

The fact that any \( d \)-dimensional Einstein manifold with cosmological constant \( \Lambda \) and constant provides a solution for \( \gamma_{ab} \) is very interesting. In higher dimensions one could use different known solutions plus the three-sphere to construct Euclidean geometries supporting meron-like configurations of the form (15). One interesting example would be, for instance, to use the Euclidean Schwarzschild-AdS or Euclidean Kerr-AdS black holes in four dimensions as the metric \( \gamma_{ab} \), to form a seven-dimensional black brane with three compact dimensions. It would be also very interesting to construct solutions with a non-constant and regular warp factor. This task, however, is quite non-trivial and it is likely that some extra ingredients are required to achieve it. We hope to come back on this issue in a future publication.

V. CONCLUSIONS

Analytic smooth configurations of Euclidean Einstein-Yang-Mills system have been constructed. The ansatz for the gauge field is of meron-type: it is proportional to a pure gauge (with a suitable parameter \( \lambda \) which is determined by solving the field equations). The smooth gauge transformation used to construct the meron cannot be deformed continuously to the identity as it possesses a non-vanishing winding number. In the three dimensional case, the solution is smooth and the spatial geometry is a three-sphere. The effects of the inclusion of a Chern-Simons term can be studied explicitly. Interestingly enough, one of the effects of the Chern-Simons term is that, unlike what happens in the pure Yang-Mills case, the parameter \( \lambda \) is in general different from 1/2: the value of \( \lambda \) in the 3D Yang-Mills-Chern-Simons case depends explicitly on the Chern-Simons coupling. In dimensions greater than three, one gets \( \lambda = 1/2 \).

In four dimensions the corresponding geometry can be interpreted as a smooth Euclidean wormhole interpolating between different vacua of the theory (thus, extending the usual flat interpretation of merons). In five dimensions regular meron-like configurations have been found, where the metric is given by the three-sphere times a constant curvature space. This last result can be extended to arbitrary higher dimensions where the metric is given by the warped product the three-sphere with any solution of the \((D-3)\)-dimensional Einstein equations in vacuum with an effective cosmological constant. In all these cases, the coupling of the meron with general relativity “regularizes” the configurations. Namely, Yang-Mills configurations (which on flat spaces would be singular) become regular when the coupling with general relativity is considered. This remarkable effect could be named gravitational catalysis of merons. One of the consequences of this fact is that, while in the flat case the Euclidean action of merons is divergent (so that a single meron gives vanishing contribution to the semi-classical path integral), gravitating merons can be smooth and regular and, consequently, they can give a non-vanishing contribution to the semi-classical path integral (as the present examples clearly show). In Cho’s approach we can express the vacuum potential \( \Omega_\mu = U^{-1} \partial_\mu U \) explicitly with \( \hat{n} = (n_1, n_2, n_3) \), and express the ansatz (11) solely by \( \hat{n} \). With this we can obtain the same result using \( \hat{n} \). A very interesting issue (on which we hope to come back in a future publication) is the resurgence analysis (along the lines of [57]) of the complex regular meron-like saddle points which appear in the Einstein-Yang-Mills-Chern-Simons case when the Chern-Simons coupling constant is taken as \( ik \).
