Abstract. In this paper, we make a slight contribution about the existence (uniqueness) and asymptotic stability of the $p$-th mean $S$-asymptotically $\omega$-periodic solutions for some nonautonomous Stochastic Evolution Equations driven by a $Q$-Brownian motion. This is done using the Banach fixed point Theorem and a Gronwall inequality.

AMS Subject Classification: 34K13; 35B10; 60G20.

Key words and phrases: $S$-asymptotically periodic solution, composition theorem, evolutionnary process, stochastic evolution equation.

1. INTRODUCTION

Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a complete probability space and $(\mathbb{H}, ||.||)$ a real separable Hilbert space. We are concerned in this paper with the existence and asymptotic stability of $p$-th mean $S$-asymptotically $\omega$-periodic solution of the following stochastic evolution equation

$$
\begin{cases}
    dX(t) = A(t)X(t)dt + f(t, X(t))dt + g(t, X(t))dW(t), & t \geq 0 \\
    X(0) = c_0,
\end{cases}
$$

where $(A(t))_{t \geq 0}$ is a family of densely defined closed linear operators which generates an exponentially stable $\omega$-periodic two-parameter evolutionnary family. The functions $f : \mathbb{R}_+ \times L^p(\Omega, \mathbb{H}) \to L^p(\Omega, \mathbb{H})$, $g : \mathbb{R}_+ \times L^p(\Omega, \mathbb{H}) \to L^p(\Omega, L^2_0)$ are continuous satisfying some additional conditions and $(W(t))_{t \geq 0}$ is a $Q$-Brownian motion.
The spaces $L^p(\Omega, \mathbb{H})$, $L^2_0$ and the Q-Brownian motion are defined in the next section.

The concept of periodicity is important in probability especially for investigations on stochastic processes. The interest in such a notion lies in its significance and applications arising in engineering, statistics, etc. In recent years, there has been an increasing interest in periodic solutions (pseudo-almost periodic, almost periodic, almost automorphic, asymptotically almost periodic, etc) for stochastic evolution equations. For instance among others, let us mentioned the existence, uniqueness and asymptotic stability results of almost periodic solutions, almost automorphic solutions, pseudo almost periodic solutions studied by many authors, see, e.g. ([1, 2, 3, 4, 5, 7, 8, 11, 12, 18, 19, 24]). The concept of $S$-asymptotically $\omega$-periodic stochastic processes, which is the central question to be treated in this paper, was first introduced in the literature by Henriquez, Pierri et al in ([16, 17]). This notion has been developed by many authors.

In the literature, there has been a significant attention devoted this concept in the deterministic case; we refer the reader to ([6, 9, 10, 11, 13, 14]) and the references therein. However, in the random case, there are few works related to the notion of $S$-asymptotically $\omega$-periodicity with regard to the existence, uniqueness and asymptotic stability for stochastic processes. To our knowledge, the first work dedicated to $S$-asymptotically $\omega$-periodicity for stochastic processes is due to S. Zhao and M. Song ([22, 23]) where they show existence of square-mean $S$-asymptotically $\omega$-periodic solutions for a class of stochastic fractional functional differential equations and for a certain class of stochastic fractional evolution equation driven by Levy noise. But until now and to the best our knowledge, there is no investigations for the existence (uniqueness), asymptotic stability of $p$-th mean $S$-asymptotically $\omega$-periodic solutions when $p > 2$.

This paper is organized as follows. Section 2 deals with some preliminaries intended to clarify the presentation of concepts and norms used latter. We also give a composition result, see Theorem 2.2. In section 3 we present theoretical results on the existence and uniqueness of $S$-asymptotically $\omega$-periodic solution of equation (1), see Theorem 3.3. We also present results on asymptotic stability of the unique $S$-asymptotically $\omega$-periodic solution of equation (1), see Theorem 3.5.

2. Preliminaries

This section is concerned with some notations, definitions, lemmas and preliminary facts which are used in what follows.

2.1. $p$-th mean $S$ asymptotically omega periodic process. Assume that the probability space $(\Omega, \mathcal{F}, P)$ is equipped with some filtration $(\mathcal{F}_t)_{t \geq 0}$ satisfying the usual conditions. Let $p \geq 2$. Denote by $L^p(\Omega, \mathbb{H})$ the collection of all strongly measurable $p$-th integrable $\mathbb{H}$-valued random variables such that

$$\mathbb{E}\|X\| = \int_\Omega \|X(\omega)\|^p dP(\omega) < \infty.$$ 

**Definition 2.1.** A stochastic process $X: \mathbb{R}_+ \to L^p(\Omega, \mathbb{H})$ is said to be continuous whenever

$$\lim_{t \to s} \mathbb{E}\|X(t) - X(s)\|^p = 0.$$ 

**Definition 2.2.** A stochastic process $X: \mathbb{R}_+ \to \mathbb{L}^p(\Omega, \mathbb{H})$ is said to be bounded if there exists a constant $C > 0$ such that
\[ \mathbb{E}[|X(t)|^p] \leq C \quad \forall t \geq 0 \]

**Definition 2.3.** A continuous and bounded stochastic process $X: \mathbb{R}_+ \to \mathbb{L}^p(\Omega, \mathbb{H})$ is said to be $p$-mean $S$-asymptotically $\omega$-periodic if there exists $\omega > 0$ such that
\[ \lim_{t \to +\infty} \mathbb{E}[|X(t + \omega) - X(t)|^p] = 0, \quad \forall t \geq 0. \]

The collection of $p$-mean $S$-asymptotically $\omega$-periodic stochastic process with values in $\mathbb{H}$ is then denoted by $\text{SAP}_p(\mathbb{L}^p(\Omega, \mathbb{H}))$.

A continuous bounded stochastic process $X$, which is $2$-mean $S$-asymptotically $\omega$-periodic is also called square-mean $S$-asymptotically $\omega$-periodic.

**Remark 2.1.** Since any $p$-mean $S$-asymptotically $\omega$-periodic process $X$ is $\mathbb{L}^p(\Omega, \mathbb{H})$ bounded and continuous, the space $\text{SAP}_p(\mathbb{L}^p(\Omega, \mathbb{H}))$ is a Banach space equipped with the sup norm:
\[ ||X||_{\infty} = \sup_{t \geq 0} \left( \mathbb{E}[|X(t)|^p] \right)^{1/p}. \]

**Definition 2.4.** A function $F: \mathbb{R}_+ \times \mathbb{L}^p(\Omega, \mathbb{H}) \to \mathbb{L}^p(\Omega, \mathbb{H})$ which is jointly continuous, is said to be $p$-mean $S$-asymptotically $\omega$ periodic in $t \in \mathbb{R}_+$ uniformly in $X \in K$ where $K \subseteq \mathbb{L}^p(\Omega, \mathbb{H})$ is bounded if for any $\epsilon > 0$ there exists $L_\epsilon > 0$ such that
\[ \mathbb{E}[|F(t + \omega, X) - F(t, X)|^p] \leq \epsilon \]
for all $t \geq L_\epsilon$ and all process $X: \mathbb{R}_+ \to K$.

**Definition 2.5.** A function $F: \mathbb{R}_+ \times \mathbb{L}^p(\Omega, \mathbb{H}) \to \mathbb{L}^p(\Omega, \mathbb{H})$ which is jointly continuous, is said to be $p$-mean asymptotically uniformly continuous on bounded sets $K' \subseteq \mathbb{L}^p(\Omega, \mathbb{H})$, if for all $\epsilon > 0$ there exists $\delta_\epsilon > 0$ such that
\[ \mathbb{E}[|F(t, X) - F(t, Y)|^p] \leq \epsilon \]
for all $t \geq \delta_\epsilon$ and every $X, Y \in K'$ with $\mathbb{E}[|X - Y|^p] \leq \delta_\epsilon$.

**Theorem 2.1.** Let $F: \mathbb{R}_+ \times \mathbb{L}^p(\Omega, \mathbb{H}) \to \mathbb{L}^p(\Omega, \mathbb{H})$ be a $p$-mean $S$-asymptotically $\omega$ periodic in $t \in \mathbb{R}_+$ uniformly in $X \in K$ where $K \subseteq \mathbb{L}^p(\Omega, \mathbb{H})$ is bounded and $p$-mean asymptotically uniformly continuous on bounded sets. Assume that $X: \mathbb{R}_+ \to \mathbb{L}^p(\Omega, \mathbb{H})$ is a $p$-mean $S$ asymptotically $\omega$-periodic process. Then the stochastic process $(F(t, X(t)))_{t \geq 0}$ is $p$-mean $S$-asymptotically $\omega$-periodic.

**Proof.** Since $X: \mathbb{R}_+ \to \mathbb{L}^p(\Omega, \mathbb{H})$ is a $p$-mean $S$-asymptotically $\omega$-periodic process, for all $\epsilon > 0$, there exists $T_\epsilon > 0$ such that for all $t \geq T_\epsilon$:
\[ \mathbb{E}[|X(t + \omega) - X(t)|^p] \leq \epsilon. \] (2)

In addition $X$ is bounded that is
\[ \sup_{t \geq 0} \mathbb{E}[|X(t)|^p] < \infty. \]

Let $K \subseteq \mathbb{L}^p(\Omega, \mathbb{H})$ be a bounded set such that $X(t) \in K$ for all $t \geq 0$.

We have:
\[ \mathbb{E}[|F(t + \omega, X(t + \omega)) - F(t, X(t))|^p] \leq 2^{p-1} \mathbb{E}[|F(t + \omega, X(t + \omega)) - F(t + \omega, X(t))|^p] + 2^{p-1} \mathbb{E}[|F(t + \omega, X(t)) - F(t, X(t))|^p] \]
Taking into account (2) and using the fact that $F$ is $p$-mean asymptotically uniformly continuous on bounded sets, there exists $\delta_\epsilon = \epsilon$ and $L_\epsilon = T_\epsilon$ such that for all $t \geq T_\epsilon$:

$$
\mathbb{E} \left| F(t + \omega, X(t + \omega)) - F(t + \omega, X(t)) \right|^p \leq \frac{\epsilon}{2^p}.
$$

Similarly, using the $p$-mean $S$-asymptotically $\omega$ periodicity in $t \geq 0$ uniformly on bounded sets of $F$ it follows that for all $t \geq T_\epsilon$:

$$
\mathbb{E} \left| F(t + \omega, X(t)) - F(t, X(t)) \right|^p \leq \frac{\epsilon}{2^p}.
$$

Bringing together the inequalities (3) and (4), we thus obtain that for all $t \geq T_\epsilon > 0$

$$
\mathbb{E} \left| F(t + \omega, X(t + \omega)) - F(t, X(t)) \right|^p \leq \epsilon
$$

so that the stochastic process $t \to F(t, X(t))$ is $p$-mean $S$-asymptotically $\omega$- periodic.

\textbf{Lemma 2.2.} Assume that $F : \mathbb{R}_+ \times L^p(\Omega, \mathbb{H}) \to L^p(\Omega, \mathbb{H})$ is $p$-mean uniformly $S$-asymptotically $\omega$-periodic in $t \in \mathbb{R}_+$ uniformly on bounded sets and satisfies the Lipschitz condition, that is, there exists constant $L(F) > 0$ such that

$$
\mathbb{E} \left| F(t, X) - F(t, Y) \right|^p \leq L(F) \mathbb{E} \left| X - Y \right|^p \quad \forall t \geq 0, \forall X, Y \in L^p(\Omega, \mathbb{H}).
$$

Let $X$ be an $p$-mean $S$ asymptotically $\omega$-periodic process, then the process $(F(t, X(t)))_{t \geq 0}$ is $p$-mean $S$-asymptotically $\omega$-periodic.

For the proof, the reader can refer to [23] whenever $p = 2$. The case $p > 2$ is similar.

Now let us recall the notion of evolutionary family of operators.

\textbf{Definition 2.6.} A two-parameter family of bounded linear operators $\{U(t, s) : t \geq s \text{ with } t, s \geq 0\}$ from $L^p(\Omega, \mathbb{H})$ into itself associate with $A(t)$ is called an evolutionary family of operators whenever the following conditions hold:

(a) $U(t, s)U(s, r) = U(t, r)$ for every $r \leq s \leq t$;

(b) $U(t, t) = I$, where $I$ is the identity operator;

(c) For all $X \in L^p(\Omega, \mathbb{H})$, the function $(t, s) \to U(t, s)X$ is continuous for $s < t$;

(d) The function $t \to U(t, s)$ is differentiable and

$$
\frac{\partial}{\partial t} U(t, s) = A(t)U(t, s) \quad \text{for every } r \leq s \leq t;
$$

For additional details on evolution families, we refer the reader to the book by Lunardi [?].

2.2. $Q$-Brownian motion and Stochastic integrals. Let $(B_n(t))_{n \geq 1}, t \geq 0$ be a sequence of real valued standard Brownian motion mutually independent on the filtered space $(\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t)$. Set

$$
W(t) = \sum_{n \geq 1} \sqrt{\lambda_n} B_n(t) e_n, \quad t \geq 0,
$$

where $\lambda_n$ are the eigenvalues of the operator $A$. The process $W(t)$ is called a $Q$-Brownian motion. The set $\{W(t) : t \geq 0\}$ is a stochastic process with continuous sample paths.
where \( \lambda_n \geq 0, \ n \geq 1 \), are nonnegative real numbers and \((e_n)_{n \geq 1}\) the complete orthonormal basis in the Hilbert space \((H, ||\cdot||)\).

Let \( Q \) be a symmetric nonnegative operator with finite trace defined by

\[
Qe_n = \lambda_n e_n \quad \text{such that} \quad Tr(Q) = \sum_{n \geq 1} \lambda_n < \infty.
\]

It is well known that \( E[W_t] = 0 \) and for all \( t \geq s \geq 0 \), the distribution of \( W(t) - W(s) \) is a Gaussian distribution \( \mathcal{N}(0, (t-s)Q) \). The above-mentioned \( H \)-valued stochastic process \( (W(t))_{t \geq 0} \) is called an \( Q \)-Brownian motion.

Let \((K, ||\cdot||_K)\) be a real separable Hilbert space.

Let also \( \mathcal{L}(K, H) \) be the space of all bounded linear operators from \( K \) into \( H \). If \( K = H \), we denote it by \( \mathcal{L}(H) \).

Set \( H_0 = Q^{1/2}H \). The space \( H_0 \) is a Hilbert space equipped with the norm \( ||u||_{H_0} = ||Q^{1/2}u|| \). Define

\[
L^0_2 = \{ \Phi \in \mathcal{L}(H_0, H) : Tr[(\Phi Q \Phi^*)] < \infty \}
\]

the space of all Hilbert-Schmidt operators from \( H_0 \) to \( H \) equipped with the norm

\[
||\Phi||_{L^0_2} = Tr[(\Phi Q \Phi^*)] = E(||\Phi Q^{1/2}||^2)
\]

In the sequel, to prove Lemma 3.2 and Theorem 3.3 we need the following Lemma that is a particular case of Lemma 2.2 in [21] (see also [12, 20]).

Assume \( T > 0 \).

**Lemma 2.3.** Let \( G : [0, T] \to \mathcal{L}(\mathbb{L}^p(\Omega, H)) \) be an \( \mathcal{F}_t \)-adapted measurable stochastic process satisfying \( \int_0^T E||G(t)||^2 dt < \infty \) almost surely. Then,

(i) The stochastic integral \( \int_0^t G(s)dW(s) \) is a continuous, square integrable martingale with values in \((H, ||\cdot||)\) such that

\[
E \left( \left| \int_0^t G(s)dW(s) \right|^2 \right) \leq E \left( \int_0^t ||G(s)||^2 ds \right).
\]

(ii) There exists some constant \( C_p > 0 \) such that the following particular case of Burkholder-Davis-Gundy inequality holds:

\[
E \sup_{0 \leq t \leq T} \left( \left| \int_0^t G(s)dW(s) \right|^p \right) \leq C_pE \left( \int_0^T ||G(s)||^2 ds \right)^{p/2}.
\]

In the sequel, we’ll frequently make use of the following inequalities:

\[
|a + b|^p \leq 2^{p-1}(|a|^p + |b|^p) \quad \text{for all} \ p \geq 1 \ \text{and any real numbers} \ a, b.
\]

\[
\int_{t_0}^t e^{-2a(t-s)} ds \leq \int_{t_0}^t e^{-a(t-s)} ds \leq \frac{1}{a} \ \forall t \geq t_0, \ \text{where} \ a > 0.
\]
3. Main results

In this section, we investigate the existence and the asymptotically stability of the $p$-th mean $S$-asymptotically $\omega$-periodic solution to the already defined stochastic differential equation:

$$dX(t) = A(t)X(t)dt + f(t, X(t))dt + g(t, X(t))dW(t), \quad X(0) = c_0$$

where $A(t), t \geq 0$ is a family of densely defined closed linear operators and

$$f : \mathbb{R}_+ \times \mathbb{L}^p(\Omega, \mathbb{H}) \to \mathbb{L}^p(\Omega, \mathbb{H}),$$

$$g : \mathbb{R}_+ \times \mathbb{L}^p(\Omega, \mathbb{H}) \to \mathbb{L}^p(\Omega, \mathbb{L}^0_2)$$

are jointly continuous satisfying some additional conditions and $(W(t))_{t \geq 0}$ is a $\mathcal{F}$-Brownian motion with values in $\mathbb{H}$ and $\mathcal{F}_t$-adapted.

Throughout the rest of this section, we require the following assumption on $U(t, s)$:

\textbf{(H1):} $A(t)$ generates an exponentially $\omega$-periodic stable evolutionnary process $(U(t, s))_{t \geq s}$ in $\mathbb{L}^p(\Omega, \mathbb{H})$, that is, a two-parameter family of bounded linear operators with the following additional conditions:

1. $U(t + \omega, s + \omega) = U(t, s)$ for all $t \geq s$ ($\omega$-periodicity).
2. There exists $M > 0$ and $a > 0$ such that $||U(t, s)|| \leq Me^{-a(t-s)}$ for $t \geq s$.

Now, note that if $A(t)$ generates an evolutionary family $(U(t, s))_{t \geq s}$ on $\mathbb{L}^p(\Omega, \mathbb{H})$ then the function $g$ defined by $g(s) = U(t, s)X(s)$ where $X$ is a solution of equation (1), satisfies the following relation

$$dg(s) = -A(s)U(t, s)X(s) + U(t, s)dX(s)$$

$$= -A(s)U(t, s)X(s) + A(s)U(t, s)X(s)ds + U(t, s)f(s, X(s))ds + U(t, s)g(s, X(s))dW(s).$$

Thus

$$dg(s) = U(t, s)f(s, X(s))ds + U(t, s)g(s, X(s))dW(s). \quad (5)$$

Integrating (5) on $[0, t]$ we obtain that

$$X(t) - U(t, 0)c_0 = \int_0^t U(t, s)f(s, X(s))ds + \int_0^t U(t, s)g(s, X(s))dW(s).$$

Therefore, we define

\textbf{Definition 3.1.} An $(\mathcal{F}_t)$-adapted stochastic process $(X(t))_{t \geq 0}$ is called a mild solution of (4) if it satisfies the following stochastic integral equation:

$$X(t) = U(t, 0)c_0 + \int_0^t U(t, s)f(s, X(s))ds + \int_0^t U(t, s)g(s, X(s))dW(s).$$

3.1. The existence of $p$-th mean $S$-asymptotically $\omega$-periodic solution. We require the following additional assumptions:

\textbf{(H.2)} The function $f : \mathbb{R}_+ \times \mathbb{L}^p(\Omega, \mathbb{H}) \to \mathbb{L}^p(\Omega, \mathbb{H})$ is $p$-mean $S$-asymptotically $\omega$ periodic in $t \in \mathbb{R}_+$ uniformly in $X \in K$ where $K \subseteq \mathbb{L}^p(\Omega, \mathbb{H})$ is a bounded
Proof. We define $f(s, \phi(s))$. Moreover the function $g$ satisfies the Lipschitz condition, that is, there exists constant $L(g) > 0$ such that

$$\|g(t, X) - g(t, Y)\|_{L^p}^p \leq L(g)\|X - Y\|_p^p \quad \forall t \geq 0, \forall X, Y \in L^p(\Omega, \mathbb{H}).$$

(H.3) The function $g : \mathbb{R}_+ \times L^p(\Omega, L^2_0) \rightarrow L^p(\Omega, L^2_0)$ is $p$-mean $\omega$-asymptotically $\omega$-periodic in $t \in \mathbb{R}_+$ uniformly in $X \in K$ where $K \subseteq L^p(\Omega, L^2_0)$ is a bounded set. Moreover the function $g$ satisfies the Lipschitz condition, that is, there exists constant $L(g) > 0$ such that

$$\|g(t, X) - g(t, Y)\|_{L^p}^p \leq L(g)\|X - Y\|_p^p \quad \forall t \geq 0, \forall X, Y \in L^p(\Omega, \mathbb{H}).$$

Lemma 3.1. We assume that hypothesis (H.1) and (H.2) are satisfied. We define the nonlinear operator $\wedge_1$ by: for each $\phi \in SAP_\omega(L^p(\Omega, \mathbb{H}))$

$$(\wedge_1 \phi)(t) = \int_0^t U(t, s)f(s, \phi(s))ds.$$ 

Then the operator $\wedge_1$ maps SAP_\omega(L^p(\Omega, \mathbb{H})) into itself.

Proof. We define $h(s) = f(s, \phi(s))$. Since the hypothesis (H.2) is satisfied, using Lemma 2.2 we deduce that the function $h$ is $p$-mean $\omega$-asymptotically $\omega$-periodic. Define $F(t) = \int_0^t U(t, s)h(s)ds$. It is easy to check that $F$ is bounded and continuous. Now we have:

$$F(t + \omega) - F(t) = \int_0^\omega U(t + \omega, s)h(s)ds + \int_0^t U(t, s)(h(s + \omega) - h(s))ds$$

$$= U(t + \omega, \omega)\int_0^\omega U(\omega, s)h(s)ds + \int_0^t U(t, s)(h(s + \omega) - h(s))ds$$

$$\mathbb{E}\|F(t + \omega) - F(t)\|_p^p \leq 2^{p-1}M^{2p}e^{-apt}\mathbb{E}\left(\int_0^\omega e^{-a(\omega-s)}\|h(s)\|ds\right)^p$$

$$+ 2^{p-1}M^p\mathbb{E}\left(\int_0^t e^{-a(t-s)}\|h(s + \omega) - h(s)\|ds\right)^p.$$ 

Let $p$ and $q$ be conjugate exponents. Using Hölder inequality, we obtain that

$$\mathbb{E}\|F(t + \omega) - F(t)\|_p^p \leq 2^{p-1}M^{2p}e^{-apt}\left(\int_0^\omega e^{-aq(\omega-s)}ds\right)^{p/q} \int_0^\omega \mathbb{E}\|h(s)\|_p^pds$$

$$+ 2^{p-1}M^p\mathbb{E}\left(\int_0^t e^{-a(t-s)}\|h(s + \omega) - h(s)\|ds\right)^p$$

$$= I(t) + J(t)$$

where

$$I(t) = 2^{p-1}M^{2p}e^{-apt}\left(\int_0^\omega e^{-aq(\omega-s)}ds\right)^{p/q} \int_0^\omega \mathbb{E}\|h(s)\|_p^pds$$

$$J(t) = 2^{p-1}M^p\mathbb{E}\left(\int_0^t e^{-a(t-s)}\|h(s + \omega) - h(s)\|ds\right)^p$$

$$= 2^{p-1}M^p\mathbb{E}\left(\int_0^t e^{-\frac{a}{2}(t-s)} \times e^{-\frac{a}{2}(t-s)}\|h(s + \omega) - h(s)\|ds\right)^p.$$ 

It is obvious that

$$\lim_{t \to +\infty} I(t) = 0.$$
Using Hölder inequality, we obtain that

\[ J(t) \leq 2^{p-1} M^p \left( \int_0^t e^{-a(t-s)} ds \right)^{p/q} \int_0^t e^{-a(t-s)} \| h(s + \omega) - h(s) \|^p ds \]

\[ \leq 2^{p-1} M^p \left( \frac{1}{a} \right)^{p/q} \int_0^t e^{-a(t-s)} \| h(s + \omega) - h(s) \|^p ds \]

Let \( \epsilon > 0 \). Since \( \lim_{u \to +\infty} \mathbb{E}[|h(u + \omega) - h(u)|^p] = 0 \):

\[ \exists T_\epsilon > 0, \ u > T_\epsilon \Rightarrow \mathbb{E}[|h(u + \omega) - h(u)|^p] \leq \frac{\epsilon a^p}{2^{p-1} M^p}. \quad (6) \]

We have

\[ J(t) \leq 2^{p-1} M^p \left( \frac{1}{a} \right)^{p/q} \int_0^{T_\epsilon} e^{-a(t-s)} \| h(s + \omega) - h(s) \|^p ds \]

\[ + 2^{p-1} M^p \left( \frac{1}{a} \right)^{p/q} \int_{T_\epsilon}^t e^{-a(t-s)} \| h(s + \omega) - h(s) \|^p ds \]

\[ = J_1(t) + J_2(t), \]

where

\[ J_1(t) = 2^{p-1} M^p \left( \frac{1}{a} \right)^{p/q} \int_0^{T_\epsilon} e^{-a(t-s)} \| h(s + \omega) - h(s) \|^p ds \]

\[ J_2(t) = 2^{p-1} M^p \left( \frac{1}{a} \right)^{p/q} \int_{T_\epsilon}^t e^{-a(t-s)} \| h(s + \omega) - h(s) \|^p ds \]

**Estimation of** \( J_1(t) \).

\[ J_1(t) \leq 2^{p-1} M^p \left( \frac{1}{a} \right)^{p/q} \int_0^{T_\epsilon} e^{-a(t-s)} \| h(s + \omega) - h(s) \|^p ds \]

\[ \leq 2^{p-1} M^p \left( \frac{1}{a} \right)^{p/q} 2^p \sup_{t \geq 0} \mathbb{E}[|h(t)|^p] e^{-at} \int_0^{T_\epsilon} e^{a_q s} ds. \]

It is clear that \( \lim_{t \to +\infty} J_1(t) = 0 \).

**Estimation of** \( J_2(t) \).

Unsing the Inequality in \( (6) \) we have

\[ J_2(t) = 2^{p-1} M^p \left( \frac{1}{a} \right)^{p/q} \int_{T_\epsilon}^t e^{-a(t-s)} \| h(s + \omega) - h(s) \|^p ds \]

\[ \leq 2^{p-1} M^p \left( \frac{1}{a} \right)^{p/q} \left( \frac{1}{a} \right)^{p/q} \frac{\epsilon a^p}{2^{p-1} M^p} \]

\[ = 2^{p-1} M^p a^{-p} \frac{\epsilon a^p}{2^{p-1} M^p} \]

\[ \leq \epsilon. \]

\( \square \)
Lemma 3.2. We assume that hypothesis (H.1) and (H.3) are satisfied. We define the nonlinear operator $\Lambda_2$ by: for each $\phi \in SAP_\omega(\mathbb{L}^p(\Omega, L^0_\omega))$

$$(\Lambda_2\phi)(t) = \int_0^t U(t, s)g(s, \phi(s))dW(s).$$

Then the operator $\Lambda_2$ maps $SAP_\omega(\mathbb{L}^p(\Omega, L^0_\omega))$ into itself.

Proof. We define $h(s) = g(s, \phi(s))$. Since the hypothesis (H.3) is satisfied, using Lemma 2.2 we deduce that the function $h$ is $p$-mean $S$ asymptotically $\omega$ periodic. Define $F(t) = \int_0^t U(t, s)h(s)ds$. It is easy to check that $F$ is bounded and continuous. We have:

$$F(t + \omega) - F(t) = \int_0^\omega U(t + \omega, s)h(s)dW(s) + \int_0^t U(t, s)(h(s + \omega) - h(s))dW(s),$$

$$= U(t + \omega, \omega)\int_0^\omega U(\omega, s)h(s)dW(s) + \int_0^t U(t, s)(h(s + \omega) - h(s))dW(s),$$

$$\mathbb{E}\|F(t + \omega) - F(t)\|^p \leq 2^{p-1}M^p\epsilon^{-\alpha p}E\left|\int_0^\omega U(\omega, s)h(s)dW(s)\right|^p + 2^{p-1}E\left|\int_0^t U(t, s)(h(s + \omega) - h(s))dW(s)\right|^p$$

$$:= I(t) + J(t)$$

where

$$I(t) = 2^{p-1}M^p\epsilon^{-\alpha p}E\left|\int_0^\omega U(\omega, s)h(s)dW(s)\right|^p$$

$$J(t) = 2^{p-1}E\left|\int_0^t U(t, s)(h(s + \omega) - h(s))dW(s)\right|^p$$

It is clear that

$$\lim_{t \to +\infty} \mathbb{E}I(t) = 0.$$  

Let $\epsilon > 0$. Since $\lim_{t \to +\infty} \mathbb{E}\|h(t + \omega) - h(t)\|^p = 0$

$$\exists T_\epsilon > 0, t > T_\epsilon \Rightarrow \mathbb{E}\|h(s + \omega) - h(s)\|_{L^p_\omega}^p \leq \frac{\epsilon (2a)^{p/2}}{4^{p-1}M^p C_p},$$  

(7) where the constant $C_p$ will be precised in the next lines. We have

$$\mathbb{E}J(t) = 2^{p-1}E\left|\int_0^t U(t, s)(h(s + \omega) - h(s))dW(s)\right|^p$$

$$\leq 4^{p-1}E\left|\int_0^{T_\epsilon} U(t, s)(h(s + \omega) - h(s))dW(s)\right|^p + 4^{p-1}E\left|\int_{T_\epsilon}^t U(t, s)(h(s + \omega) - h(s))dW(s)\right|^p$$

$$:= \mathbb{E}J_1(t) + \mathbb{E}J_2(t),$$
where

\[ J_1(t) = 4^{p-1} \left\| \int_0^T U(t, s)(h(s + \omega) - h(s)) dW(s) \right\|_p \]

\[ J_2(t) = 4^{p-1} \left\| \int_T^t U(t, s)(h(s + \omega) - h(s)) dW(s) \right\|_p \]

Note that for all \( t \geq 0 \), \( h(t + \omega) - h(t) \in L^p(\Omega, L^2_t) \subseteq L^2(\Omega, L^2_t) \) and

\[
\int_0^t E\|U(t, s)(h(s + \omega) - h(s))\|^2 ds \leq M^2 \int_0^t e^{-2\alpha(t-s)} E\|h(s + \omega) - h(s)\|_{L^2}^2 ds \\
\leq 4M^2 \sup_{t \geq 0} E\|h(t)\|_{L^2}^2 \int_0^t e^{-2\alpha(t-s)} ds \\
\leq 4M^2a^{-2} \sup_{t \geq 0} E\|h(t)\|_{L^2}^2 \\
< \infty.
\]

Estimation of \( EJ_1(t) \).

Assume that \( p > 2 \). Using Hölder inequality between conjugate exponents \( \frac{1}{p} \) and \( \frac{1}{2} \) together with Lemma 2.3 part (ii), there exists constant \( C_p \) such that:

\[
EJ_1(t) \leq C_p 4^{p-1} M^p E \left[ \int_0^T e^{-2\alpha(t-s)} \|h(s + \omega) - h(s)\|_{L^2}^2 ds \right]^{p/2} \\
\leq C_p 4^{p-1} M^p \left( \int_0^T e^{-2\alpha p(t-s)} ds \right)^{p/2} \int_0^T E\|h(s + \omega) - h(s)\|_{L^2}^p ds \\
\leq C_p 4^{p-1} M^p e^{-\alpha pt} \left( \int_0^T e^{-2\alpha p(s-t)} ds \right)^{p/2} T^p \sup_{s \geq 0} E\|h(s)\|_{L^2}^p.
\]

Therefore

\[
\lim_{t \to +\infty} EJ_1(t) = 0.
\]

Assume that \( p = 2 \). By Lemma 2.3 part (i) we get:

\[
EJ_1(t) \leq 4M^2 E \left[ \int_0^T e^{-\alpha(t-s)} \|h(s + \omega) - h(s)\|_{L^2} dB(s) \right]^2 \\
\leq 4M^2E \left[ \int_0^T e^{-2\alpha(t-s)} \|h(s + \omega) - h(s)\|_{L^2}^2 ds \right] \\
\leq 16M^2e^{-2\alpha t} \sup_{s \geq 0} E\|h(s)\|_{L^2}^2 \int_0^T e^{2\alpha s} ds \\
\leq 16M^2e^{-2\alpha t} \sup_{s \geq 0} E\|h(s)\|_{L^2}^2 \int_0^T e^{2\alpha s} ds \\
\]

Thus

\[
\lim_{t \to +\infty} EJ_1(t) = 0.
\]
Estimation of $\mathbb{E}J_2(t)$.

Assume that $p > 2$. Using again Lemma 2.3 part (ii), Hölder inequality between between conjugate exponents $\frac{p}{p-2}$ and $\frac{p}{2}$ and the inequality in (7) we have

$$
\mathbb{E}J_2(t) = 4^{p-1}\mathbb{E}\left|\int_{T_t}^t U(t,s)(h(s+\omega) - h(s))dW(s)\right|^p \\
\leq 4^{p-1}M^pC_p\mathbb{E}\left[\int_{T_t}^t e^{-2\alpha(t-s)}||h(s+\omega) - h(s)||_{L^2}^2ds\right]^{p/2} \\
= 4^{p-1}M^pC_p\mathbb{E}\left[\int_{T_t}^t e^{-2\alpha(t-s)}\frac{\partial}{\partial s}\times e^{-2\alpha(t-s)}\frac{\partial}{\partial s}||h(s+\omega) - h(s)||_{L^2}^2ds\right]^{p/2} \\
\leq C_p4^{p-1}M^p\left(\int_{T_t}^t e^{-2\alpha(t-s)}ds\right)^{p/2} \int_{T_t}^t e^{-2\alpha(t-s)}\mathbb{E}||h(s+\omega) - h(s)||_{L^2}^p ds \\
\leq \frac{C_p4^{p-1}M^p(2\alpha)^{p/2}}{C_p4^{p-1}M^p} \left(\int_{T_t}^t e^{-2\alpha(t-s)}ds\right)^{p/2} \\
\leq \epsilon.
$$

We conclude that

$$
\lim_{t\to+\infty} \mathbb{E}J_2(t) = 0.
$$

Assume that $p = 2$. By Lemma 2.3 part (i) and Cauchy-Schwarz inequality we have

$$
\mathbb{E}J_2(t) = 4\mathbb{E}\left|\int_{T_t}^t U(t,s)(h(s+\omega) - h(s))dW(s)\right|^2 \\
\leq 4M^2\mathbb{E}\left[\int_{T_t}^t e^{-2\alpha(t-s)}||h(s+\omega) - h(s)||_{L^2}^2ds\right] \\
= 4M^2\left[\int_{T_t}^t e^{-\alpha(t-s)}\times e^{-\alpha(t-s)}\mathbb{E}||h(s+\omega) - h(s)||_{L^2}^2ds\right] \\
\leq 4M^2\left(\int_{T_t}^t e^{-2\alpha(t-s)}ds\right)^{1/2} \left(\int_{T_t}^t e^{-2\alpha(t-s)}(\mathbb{E}||h(s+\omega) - h(s)||_{L^2}^2)ds\right)^{1/2} \\
\leq 4M^2\left(\int_{T_t}^t e^{-2\alpha(t-s)}ds\right)^{1/2} \left(\int_{T_t}^t e^{-2\alpha(t-s)}ds\right)^{1/2} \\
\leq \epsilon.
$$

Note also that for $t \geq T_t$ :

$$
\mathbb{E}||h(s+\omega) - h(s)||_{L^2}^2 \leq \frac{\epsilon a}{2M^2}
$$

so that

$$
\mathbb{E}J_2(t) \leq \frac{4M^2\epsilon a}{2M^2} \left(\int_{T_t}^t e^{-2\alpha(t-s)}ds\right) \\
\leq \epsilon.
$$

This implies that

$$
\lim_{t\to+\infty} \mathbb{E}J_2(t) = 0.
$$

Finally, we conclude that

$$
\lim_{t\to+\infty} \mathbb{E}|F(t+\omega) - F(t)|^p = 0
$$
Theorem 3.3. We assume that hypothesis (H.1), (H.2) and (H.3) are satisfied and

(i)

\[ \Theta = 2^{p-1}M^p(L(f)a^{-p} + C_p L(g)a^{-p}) < 1 \quad \text{if } p > 2 \]  (8)

(ii)

\[ \Xi = 2M^2(L(f)\frac{1}{a^2} + L(g)\frac{1}{a}) < 1 \quad \text{if } p = 2. \]  (9)

Then the stochastic evolution equation (1) has a unique \( p \)-mean \( S \)-asymptotically \( \omega \)-periodic solution.

Proof. We define the nonlinear operator \( \Gamma \) by the expression

\[ (\Gamma \Phi)(t) = U(t,0)c_0 + \int_0^t U(t,s)f(s,\Phi(s))ds + \int_0^t U(t,s)g(s,\Phi(s))dW(s) \]

Note that

\[ (\Gamma \Phi)(t) = U(t,0)c_0 + (\land_1 \Phi)(t) + (\land_2 \Phi)(t) \]

According to the hypothesis (H1) we have:

\[ \mathbb{E}||U(t+\omega,0) - U(t,0)||^p \leq 2^{p-1}(\mathbb{E}||U(t+\omega,0)||^p + \mathbb{E}||U(t,0)||^p) \]

\[ \leq 2^{p-1}M^p e^{-ap(t+\omega)} + M^p e^{-ap(t)} \]

\[ = 2^{p-1}M^p e^{-ap(t+\omega)}(e^{-ap\omega} + 1) \]

Therefore

\[ \lim_{t\to+\infty} \mathbb{E}||U(t+\omega,0) - U(t,0)||^p = 0. \]

According to Lemma 3.1 and Lemma 3.2 the operators \( \land_1 \) and \( \land_2 \) maps the space of \( p \)-mean \( S \)-asymptotically \( \omega \)-periodic solutions into itself. Thus \( \Gamma \) maps the space of \( p \)-mean \( S \)-asymptotically \( \omega \)-periodic solutions into itself. We have

\[ \mathbb{E}||\Gamma \Phi(t) - \Gamma \Psi(t)||^p \leq 2^{p-1}E \left( \int_0^t |U(t,s)||f(s,\Phi(s)) - f(s,\Psi(s))|ds \right)^p \]

\[ + 2^{p-1}E \left( \int_0^t |U(t,s)||g(s,\Phi(s)) - g(s,\Psi(s))|dW(s) \right)^p \]

\[ \leq 2^{p-1}M^p E \left( \int_0^t e^{-a(t-s)} |f(s,\Phi(s)) - f(s,\Psi(s))|ds \right)^p \]

\[ + 2^{p-1}M^p E \left( \int_0^t e^{-a(t-s)} |g(s,\Phi(s)) - g(s,\Psi(s))|dW(s) \right)^p \]

Case \( p > 2 \) : By Lemma 2.3 part (ii) and Hölder inequality we have
This implies that
\[
E[\|\Gamma_t - \Gamma\Psi(t)\|^p] \leq 2^{p-1}M^pL(f)\left(\int_0^t e^{-a(t-s)} ds\right)^{p-1}\int_0^t e^{-a(t-s)} E[\|\Phi(s) - \Psi(s)\|^p] ds \\
+ 2^{p-1}M^pC_\Phi\left(\int_0^t e^{-2\alpha(t-s)} \|g(s, \Phi(s)) - g(s, \Psi(s))\|^2_{L^2} ds\right)^{p/2} \\
\leq 2^{p-1}M^pL(f) \sup_{s \geq 0} E[\|\Phi(s) - \Psi(s)\|^p] \left(\int_0^t e^{-a(t-s)} ds\right)^p \\
+ 2^{p-1}M^pC_\Psi\left(\int_0^t e^{-a(t-s)} \|g(s, \Phi(s)) - g(s, \Psi(s))\|^2_{L^2} ds\right)^{p/2} \\
\leq 2^{p-1}M^pL(f) \sup_{s \geq 0} \|\Phi - \Psi\|^p \\
+ 2^{p-1}M^pC_\Phi\left(\int_0^t e^{-\alpha(t-s)} \|\Phi(s) - \Psi(s)\|^2_{L^2} ds\right)^{p/2} \\
\leq 2^{p-1}M^pL(f) \sup_{s \geq 0} \|\Phi - \Psi\|^p \\
+ 2^{p-1}M^pC_\Phi\left(\int_0^t e^{-\alpha(t-s)} ds\right)^{p/2} \times \\
\int_0^t e^{-\alpha(t-s)} E[\|g(s, \Phi(s)) - g(s, \Psi(s))\|^p_{L^2} ds \\
\leq 2^{p-1}M^p\left(L(f) \sup_{s \geq 0} E[\|\Phi(s) - \Psi(s)\|^p] + C_\Phi L(g) a^{-\frac{p}{q}}\right) \|\Phi - \Psi\|^p_{L^\infty}.
\]

This implies that
\[
\|\Gamma_t - \Gamma\Psi\|^p_{L^\infty} \leq 2^{p-1}M^p\left(L(f) \sup_{s \geq 0} E[\|\Phi(s) - \Psi(s)\|^p] + C_\Phi L(g) a^{-\frac{p}{q}}\right) \|\Phi - \Psi\|^p_{L^\infty}.
\]

Consequently, if \(\Theta < 1\), then \(\Gamma\) is a contraction mapping. One completes the proof by the Banach fixed-point principle.

Case \(p = 2\) : using Cauchy-Schwarz inequality and Lemma 2.3 part (i), we obtain
\[
E[\|\Gamma_t - \Gamma\Psi(t)\|^2] \leq 2M^2\left(\int_0^t e^{-a(t-s)} ds\right)^2 E\int_0^t e^{-a(t-s)} \|f(s, \Phi(s)) - f(s, \Psi(s))\|^2 ds \\
+ 2M^2E\int_0^t e^{-2\alpha(t-s)} \|g(s, \Phi(s)) - g(s, \Psi(s))\|^2_{L^2} ds \\
\leq 2M^2L(f) \sup_{s \geq 0} E[\|\Phi(s) - \Psi(s)\|^2] \left(\int_0^t e^{-a(t-s)} ds\right)^2 \\
+ 2M^2L(g) \sup_{s \geq 0} E[\|\Phi(s) - \Psi(s)\|^2] \int_0^t e^{-2\alpha(t-s)} ds \\
\leq 2M^2\left(L(f) \frac{1}{a^2} + L(g) \frac{1}{a}\right) \sup_{s \geq 0} E[\|\Phi(s) - \Psi(s)\|^2] \]

This implies that
\[
\|\Gamma_t - \Gamma\Psi\|^2_{L^\infty} \leq 2M^2\left(L(f) \frac{1}{a^2} + L(g) \frac{1}{a}\right) \|\Phi - \Psi\|^2_{L^\infty}.
\]

Consequently, if \(\Xi < 1\), then \(\Gamma\) is a contraction mapping. One completes the proof by the Banach fixed-point principle.
3.2. **Stability of $p$-mean S asymptotically $\omega$ periodic solution.** In the previous section, for the non linear SDE, we obtain that it has a unique $p$-mean S-asymptotically $\omega$-periodic solution under some conditions. In this section, we will show that the unique $p$ mean S asymptotically $\omega$ periodic solution is asymptotically stable in the $p$ mean sense.

Recall that

**Definition 3.2.** The unique $p$-mean S asymptotically $\omega$ periodic solution $X^*(t)$ of (1) is said to be stable in $p$-mean sense if for any $\epsilon > 0$, there exists $\delta > 0$ such that

$$E\|X(t) - X^*(t)\|^p < \epsilon, \quad t \geq 0,$$

whenever $E\|X(0) - X^*(0)\|^p < \delta$, where $X(t)$ stands for a solution of (1) with initial value $X(0)$.

**Definition 3.3.** The unique $p$-mean S asymptotically $\omega$ periodic solution $X^*(t)$ is said to be asymptotically stable in $p$-mean sense if it is stable in $p$-mean sense and

$$\lim_{t \to \infty} E\|X(t) - X^*(t)\|^p = 0.$$

The following Gronwall inequality is proved to be useful in our asymptotical stability analysis.

**Lemma 3.4.** Let $u(t)$ be a non negative continuous functions for $t \geq 0$, and $\alpha, \gamma$ be some positive constants. If

$$u(t) \leq \alpha e^{-\beta t} + \gamma \int_0^t e^{-\beta(t-s)} u(s) ds, \quad t \geq 0,$$

then

$$u(t) \leq \alpha \exp\{(-\beta + \gamma)t\}.$$

**Theorem 3.5.** Suppose that hypothesis (H.1), (H.2) and (H.3) are satisfied and assume that

(i) $$3^{p-1}M^p (L(f)a^{1-p} + L(g)C_p a^{2-p}) < a$$

whenever $p > 2$.

(ii) $$3M^2 (L(f)a^{-1} + L(g)) < a$$

whenever $p = 2$.

Then the $p$-mean S-asymptotically solution $X^*_t$ of (1) is asymptotically stable in the $p$-mean sense.

**Remark 3.1.** Note that the above conditions (13) respectively (14) implies conditions (8) respectively (9) of Theorem 3.3.

**Proof.**

$$E\|X(t) - X^*(t)\|^p = E\left\|U(t, 0)(X(0) - X^*(0)) + \int_0^t U(t, s)(f(s, X(s)) - f(s, X^*(s))) ds + \int_0^t U(t, s)(g(s, X(s)) - g(s, X^*(s))) dW(s)\right\|^p$$
Assume that \( p > 2 \). Using H"{o}lder inequality we have

\[
\mathbb{E}|X(t) - X^*(t)|^p \leq 3^{p-1}M^p e^{-ap^2t} \mathbb{E}|X(0) - X^*(0)|^p \\
+ 3^{p-1} \mathbb{E} \left( \int_0^t |U(s)| \left| |f(s, X(s)) - f(s, X^*(s))|ds \right|^p \right) \\
+ 3^{p-1} \mathbb{E} \left( \int_0^t |g(s, X(s)) - g(s, X^*(s))|dW(s) \right)^p \\
\leq 3^{p-1}M^p e^{-ap^2t} \mathbb{E}|X(0) - X^*(0)|^p \\
+ 3^{p-1}M^p \mathbb{E} \left( \int_0^t e^{-a(t-s)} |f(s, X(s)) - f(s, X^*(s))|ds \right)^p \\
+ 3^{p-1}M^p \mathbb{E} \left( \int_0^t e^{-a(t-s)} |g(s, X(s)) - g(s, X^*(s))|dW(s) \right)^p \\
= 3^{p-1}M^p e^{-ap^2t} \mathbb{E}|X(0) - X^*(0)|^p + 3^{p-1}M^p \times \left( \\
\mathbb{E} \left( \int_0^t e^{-a(t-s)} \mathbb{E}^p |f(s, X(s)) - f(s, X^*(s))|ds \right)^p \\
+ 3^{p-1}M^p C_p \times \left( \\
\left( \int_0^t e^{-2a(t-s)} e^{-a(t-s)} \mathbb{E}|g(s, X(s)) - g(s, X^*(s))|_{L^2}^2 \right)^{p/2} \right) \right) \\
\leq 3^{p-1}M^p e^{-ap^2t} \mathbb{E}|X(0) - X^*(0)|^p \\
+ 3^{p-1}M^p L(f) \left( \int_0^t e^{-a(t-s)} ds \right)^{p-1} \times \left( \\
\int_0^t e^{-a(t-s)} \mathbb{E}|X(s) - X^*(s)|^p ds \right) \\
+ 3^{p-1}M^p C_p \left( \int_0^t e^{-2a(t-s)} \right)^{\frac{p-2}{2}} \times \left( \\
\int_0^t e^{-2a(t-s)} \mathbb{E}|g(s, X(s)) - g(s, X^*(s))|_{L^2}^p ds \right)
\]

so that

\[
\mathbb{E}|X(t) - X^*(t)|^p \leq 3^{p-1}M^p e^{-ap^2t} \mathbb{E}|X(0) - X^*(0)|^p \\
+ 3^{p-1}M^p L(f) \left( \frac{1}{a} \right)^{p-1} \int_0^t e^{-a(t-s)} \mathbb{E}|X(s) - X^*(s)|^p ds \\
+ 3^{p-1}M^p C_p L(g) \left( \frac{1}{a} \right)^{\frac{p-2}{2}} \int_0^t e^{-a(t-s)} \mathbb{E}|X(s) - X^*(s)|^p ds.
\]

Using Lemma 3.4 we obtain:

\[
\mathbb{E}|X(t) - X^*(t)|^p \leq 3^{p-1}M^p e^{-ap^2t} \mathbb{E}|X(0) - X^*(0)|^p \times \\
\exp \left\{ \left( -a + 3^{p-1}M^p (L(f)a^{1-p} + L(g)C_p a^{\frac{2-p}{2}}) \right) t \right\}.
\]
Straightforwardly, we obtain that $X(t)$ converges to 0 exponentially fast if

$$-a + 3^{p-1}M^p\left(L(f)\left(\frac{1}{a}\right)^{p-1} + L(g)C_P a^{\frac{2-p}{p}}\right) < 0,$$

which is equivalent to our condition (13). Therefore $X^*$ is asymptotically stable in the $p$-mean sense.

Assume that $p = 2$. We have

$$
\mathbb{E}\|X(t) - X^*(t)\|^2 \leq 3M^2e^{-at}\mathbb{E}\|X(0) - X^*(0)\|^2
+ 3\mathbb{E}\left(\int_0^t \|U(t, s)\|\|f(s, X(s)) - f(s, X^*(s))\|ds\right)^2
+ 3\mathbb{E}\left(\int_0^t \|U(t, s)\|\|g(s, X(s)) - g(s, X^*(s))\|dW(s)\right)^2
\leq 3M^2e^{-at}\mathbb{E}\|X(0) - X^*(0)\|^2
+ 3M^2\mathbb{E}\left(\int_0^t e^{-a(t-s)}\|f(s, X(s)) - f(s, X^*(s))\|ds\right)^2
+ 3M^2\mathbb{E}\left(\int_0^t e^{-a(t-s)}\|g(s, X(s)) - g(s, X^*(s))\|dW(s)\right)^2.
$$

Then using Cauchy-Schwartz inequality and Lemma 2.3 part (i), we have

$$
\mathbb{E}\|X(t) - X^*(t)\|^2 \leq 3M^2e^{-at}\mathbb{E}\|X(0) - X^*(0)\|^2
+ 3M^2 \int_0^t e^{-a(t-s)}ds \int_0^t e^{-a(t-s)}\mathbb{E}\|f(s, X(s)) - f(s, X^*(s))\|^2 ds
+ 3M^2 \int_0^t e^{-2a(t-s)} E\|g(s, X(s)) - g(s, X^*(s))\|^2_{L_2} ds,
\leq 3M^2e^{-at}\mathbb{E}\|X(0) - X^*(0)\|^2
+ 3M^2 L(f)a^{-1} \int_0^t e^{-a(t-s)}\mathbb{E}\|X(s) - X^*(s)\|^2 ds
+ 3M^2 L(g) \int_0^t e^{-a(t-s)}\mathbb{E}\|X(s) - X^*(s)\|^2 ds.
$$

Thus

$$
\mathbb{E}\|X(t) - X^*(t)\|^2 \leq 3M^2e^{-at}\mathbb{E}\|X(0) - X^*(0)\|^2
+ \left(\frac{3M^2L(f)}{a} + 3M^2L(g)\right) \int_0^t e^{-a(t-s)}\mathbb{E}\|X(s) - X^*(s)\|^2 ds
$$

By Lemma 3.3 we have

$$
\mathbb{E}\|X(t) - X^*(t)\|^2 \leq 3M^2\mathbb{E}\|X(0) - X^*(0)\|^2 \exp\left\{\left(-a + 3M^2\left(\frac{L(f)}{a} + L(g)\right) \right) t\right\}.
$$

Therefore $\mathbb{E}\|X(t) - X^*(t)\|^2$ converges to 0 exponentially fast whenever condition (14) holds. In particular the unique $S$-asymptotically $\omega$-periodic solution is asymptotically stable in square mean sense.
