The Bruhat order on conjugation-invariant sets of involutions in the symmetric group

Mikael Hansson†

Department of Mathematics, Linköping University, Sweden

Abstract. Let $I_n$ be the set of involutions in the symmetric group $S_n$, and for $A \subseteq \{0, 1, \ldots, n\}$, let

$$F_n^A = \{ \sigma \in I_n \mid \sigma \text{ has } a \text{ fixed points for some } a \in A \}.$$

We give a complete characterisation of the sets $A$ for which $F_n^A$, with the order induced by the Bruhat order on $S_n$, is a graded poset. In particular, we prove that $F_n^{\{1\}}$ (i.e., the set of involutions with exactly one fixed point) is graded, which settles a conjecture of Hultman in the affirmative. When $F_n^A$ is graded, we give its rank function. We also give a short new proof of the EL-shellability of $F_n^{\{0\}}$ (i.e., the set of fixed point-free involutions), which was recently proved by Can, Cherniavsky, and Twelbeck.

Résumé. Soit $I_n$ l’ensemble d’involutions dans le groupe symétrique $S_n$, et pour $A \subseteq \{0, 1, \ldots, n\}$, soit

$$F_n^A = \{ \sigma \in I_n \mid \sigma \text{ a points fixes pour quelque } a \in A \}.$$

Nous caractérisons tous les ensembles $A$ dont les $F_n^A$, avec l’ordre induit par l’ordre de Bruhat sur $S_n$, est un poset gradué. En particulier, nous démontrons que $F_n^{\{1\}}$ (c’est-à-dire, l’ensemble d’involutions avec précis en point fixe) est gradué, ce qui résout une conjecture d’Hultman à l’affirmative. Lorsque $F_n^A$ est gradué, nous donnons sa fonction de rang. En plus, nous donnons une nouvelle démonstration courte l’EL-shellability de $F_n^{\{0\}}$ (c’est-à-dire, l’ensemble d’involutions sans points fixes), établie récemment par Can, Cherniavsky et Twelbeck.

Keywords: Bruhat order, symmetric group, involution, conjugacy class, graded poset, EL-shellability

1 Introduction

Partially ordered by the Bruhat order, the symmetric group $S_n$ is a graded poset whose rank function is given by the number of inversions, and Edelman [4] proved that it is EL-shellable. Richardson and Springer [10] proved that the set $I_n$ of involutions in $S_n$ and the set $F_n^0$ of fixed point-free involutions are graded. Incitti [9] proved that the rank function of $I_n$ can be expressed as the average of the number of inversions and the number of exceedances, and that $I_n$ is EL-shellable. Hultman [8] studied (in a more general setting, which we shall describe shortly) $F_n^0$ and $F_n^1$, the set of involutions with exactly one

fixed point. It follows that $F^0_n$ is graded and Hultman conjectured that the same is true for $F^1_n$. Can, Cherniavsky, and Twelbeck [3] recently proved that $F^0_n$ is EL-shellable.

We consider the following generalisation. For $a \in \{0, 1, \ldots, n\}$, let $F^a_n$ be the conjugacy class in $S_n$ consisting of the involutions with $a$ fixed points, and for $A \subseteq \{0, 1, \ldots, n\}$, let

$$F^A_n = \bigcup_{a \in A} F^a_n.$$  

Both $I_n$ and $F^A_n$ are regarded as posets with the order induced by the Bruhat order on $S_n$. Note that

$$F^A_n = \{\sigma \in I_n \mid \sigma \text{ has } a \text{ fixed points for some } a \in A\}.$$  

Also note that for all elements in $I_n$, the number of fixed points is congruent to $n$ modulo 2. Hence, we may assume that all members of $A$ have the same parity as $n$.

Depicted in Figures 1 and 2 are the Hasse diagrams of $I_4$, $F^0_4$, and $F^2_4$.

\begin{figure}[h]

\caption{Hasse diagrams of $F^0_4$ (left) and $F^2_4$ (right).}
\end{figure}

Our main result is a complete characterisation of the sets $A$ for which $F^A_n$ is graded. In particular, we prove that $F^1_n$ is graded.

Informally, $F^A_n$ is graded precisely when $A - \{n\}$ is empty or an “interval,” which may consist of a single element if it is 0, 1, or $n - 2$. The following theorem, which is our main result, makes the above precise. It also gives the rank function of $F^A_n$ when it exists.
The Bruhat order on conjugation-invariant sets of involutions

549

Theorem 1 The poset $F^A_n$ is graded if and only if $A - \{n\} = \emptyset$ or $A - \{n\} = \{a_1, a_1 + 2, \ldots, a_2\}$ with $a_1 \in \{0, 1\}$, $a_2 = n - 2$, or $a_2 - a_1 \geq 2$. Furthermore, when $F^A_n$ is graded, its rank function $\rho$ is given by

$$\rho(\sigma) = \frac{\text{inv}(\sigma) + \text{exc}(\sigma) - n + \tilde{a}}{2} + \begin{cases} 1 & \text{if } n \in A \\ 0 & \text{otherwise}, \end{cases}$$

where $\text{inv}(\sigma)$ and $\text{exc}(\sigma)$ denote the number of inversions and exceedances, respectively, of $\sigma$, and $\tilde{a} = \max(A - \{n\})$. In particular, $F^A_n$ has rank $\rho(F^A_n) = \frac{n^2 - a^2 - 2n + 2\tilde{a}}{4} + \begin{cases} 1 & \text{if } n \in A \\ 0 & \text{otherwise}, \end{cases}$

where $a = \min A$.

The following result is direct consequence of Theorem 1.

Corollary 2 The posets $F^0_n$, $F^1_n$, $F^{n-2}_n$, and $F^n_n$ are the only graded conjugacy classes of involutions in $S_n$. Furthermore, the rank function $\rho$ of $F^0_n$ and $F^1_n$ is given by

$$\rho(\sigma) = \frac{\text{inv}(\sigma) - \lfloor n/2 \rfloor}{2},$$

and the rank function $\rho$ of $F^{n-2}_n$ is given by

$$\rho(\sigma) = \frac{\text{inv}(\sigma) - 1}{2}.$$

It is well known that $F^{n-2}_n$ is graded (in fact, it coincides with the root poset of the Weyl group $A_{n-1} \cong S_n$). As was mentioned above, the gradedness of $F^0_n$ was proved by Richardson and Springer, and that of $F^1_n$ was conjectured by Hultman. These two posets are special cases of a more general construction from Hultman’s paper [8], which we now describe.

(i) The results below are taken from [6, 7, 8]. In general, we do not indicate which results are from which paper. For general Coxeter group terminology and results, see [2].

Given a finitely generated Coxeter system $(W, S)$ and an involutive automorphism $\theta$ of $(W, S)$ (i.e., a group automorphism $\theta$ of $W$ such that $\theta(S) = S$ and $\theta^2 = \text{id}$), let

$$\iota(\theta) = \{\theta(w^{-1})w \mid w \in W\}$$

and

$$\mathcal{I}(\theta) = \{w \in W \mid \theta(w) = w^{-1}\}$$

be the sets of twisted identities and twisted involutions, respectively. Clearly, $\iota(\theta) \subseteq \mathcal{I}(\theta) \subseteq W$. Note that when $\theta = \text{id}$, $\iota(\theta)$ and $\mathcal{I}(\theta)$ reduce to the sets of the (ordinary) identity and (ordinary) involutions in $W$. Each subset of $W$ is regarded as a poset with the order induced by the Bruhat order on $W$. When $W$ is the symmetric group $S_n$, there is a unique non-trivial automorphism of $(W, S)$, mapping $s_i = (i, i + 1)$ to $s_{n-i}$. 

\[\text{(i)}\] The results below are taken from [6,7,8]. In general, we do not indicate which results are from which paper. For general Coxeter group terminology and results, see [2].
We say that $\theta$ has the \textit{no odd flip property} if the order of $s\theta(s)$ is even or infinite for all $s \in S$ with $s \neq \theta(s)$. If $W$ is finite and irreducible, then $\theta$ has the no odd flip property, unless $W$ is of type $A_{2n} \cong S_{2n+1}$ or $I_2(2n+1)$ for some $n \geq 1$, and $\theta$ is the unique non-trivial automorphism. The poset $\mathcal{J}(\theta)$ is always graded. Furthermore, we have the following result, from which it follows that $F_n^0$ is graded, as we shall see.

\textbf{Theorem A (8 Theorem 4.6 and Proposition 6.7)} If $\theta$ has the no odd flip property, then $\iota(\theta)$ is graded with the same rank function as $\mathcal{J}(\theta)$.

If $W$ is finite, it contains a greatest element $w_0$, and $\theta(w) = w_0 w w_0$ defines an involutive automorphism of $(W, S)$. Since $\iota(\theta) = \{w_0 w^{-1} w_0 w \mid w \in W\}$ and $\mathcal{J}(\theta) = \{w \in W \mid w_0 w w_0 = w^{-1}\}$,

$$w_0 \cdot \iota(\theta) = \{w^{-1} w_0 w \mid w \in W\}$$

and

$$w_0 \cdot \mathcal{J}(\theta) = \{w_0 w \mid w_0 w w_0 = w^{-1}\} = \{w_0 w \mid (w_0 w)^2 = e\}.$$

Since left (as well as right) multiplication by $w_0$ is a poset anti-automorphism (i.e., an order-reversing bijection whose inverse is order-reversing), $\iota(\theta)$ is isomorphic to the dual of $[w_0]$, where $[w_0]$ is the conjugacy class of $w_0$, and $\mathcal{J}(\theta)$ is isomorphic to the dual of $I(W)$, where $I(W)$ is the set of involutions in $W$.

When $W$ is the symmetric group $S_n$, this $\theta$ is the unique non-trivial automorphism of $(W, S)$, and $I(W) = I_n$. For $n$ even, $[w_0] = F_n^0$, and for $n$ odd, $[w_0] = F_n^1$. Thus, it follows from Theorem A that $F_n^0$ is graded.

It was conjectured by Hultman [8 Conjecture 6.1] that $\iota(\theta)$ is graded when $W = A_{2n}$. As we have seen, this is equivalent to $F_n^0$ being graded, which is the case (see Corollary 2). Since $\iota(\theta)$ is graded whenever $W$ is dihedral, as is easily seen, it therefore follows that $\iota(\theta)$ is graded whenever $W$ is finite and irreducible. From this, we get the following (we omit the proof):

\textbf{Theorem 3} If $W$ is finite, then $\iota(\theta)$ is graded.

Let us also mention a connection to work by Richardson and Springer [10] [11], who studied a graded poset $V$ of orbits of certain symmetric varieties (depending on, inter alia, a group $G$). They did so by defining an order-preserving function $\varphi : V \to \mathcal{J}(\theta) \subseteq W$ (where the Weyl group $W$ depends on, inter alia, $G$).

When $W = S_n$, $\mathcal{J}(\theta)$ is the image of an injective $\varphi$ (for details, see [10] Example 10.2). When $n$ is even, the same is true for $\iota(\theta)$ (see [10] Example 10.4) or [8] Example 3.1). Thus, $I_n$ and $F_n^0$ are isomorphic to the duals of such posets $V$. Hence, $I_n$ and $F_n^0$ are graded.

However, these are not the only $F_n^A$ that occur as the image of a $\varphi$. To describe these sets, and for later purposes, define

$$F_n^{\leq a} = \bigcup_{i \geq 0} F_n^{a-2i} \quad \text{and} \quad F_n^{\geq a} = \bigcup_{i \geq 0} F_n^{a+2i},$$

and for $a = a_1 + 2m$, where $m$ is a positive integer, let

$$F_n^{a_1:2a_2} = F_n^{\geq a_1} \cap F_n^{\leq a_2}.$$
As described in [10], the image of $\varphi$ can be read off from the corresponding Satake diagram. It follows from Satake diagrams A III and A IV in Helgason [5, Table VI] that for each $a \leq n - 2$, $F^g_n$ is the image of a $\varphi$. (From Satake diagrams A I and A II, it follows that $\mathcal{I}(\theta)$ and $\iota(\theta)$, respectively, are the images of such functions).

The remainder of this extended abstract is organised as follows. In Section 2 we agree on notation and gather the necessary definitions and previous results. Then, in Section 3 we sketch the proof of our main result (Theorem 1). Finally, in Section 4 we give a short new proof of the following result, which was recently proved by Can, Cherniavsky, and Twelbeck.

**Theorem B** (3, Theorem 1) The poset $F^0_n$ is EL-shellable.

## 2 Notation and preliminaries

Poset notation and terminology will follow [12]. In particular, if $P$ is a poset and $x \leq y$ in $P$, then $[x, y] = \{z \in P \mid x \leq z \leq y \}$ and $(x, y) = \{z \in P \mid x < z < y\}$. Furthermore, in a finite poset $P$, $<$ denotes the covering relation, a chain $x_0 < x_1 < \cdots < x_k$ is saturated if $x_{i-1} < x_i$ for all $i \in [k]$, $P$ is bounded if it has a minimum (denoted by $0$) and a maximum (denoted by $1$), and $P$ is graded of rank $n$ if every maximal chain has length $n$. In this case, there is a unique rank function $\rho : P \to \{0, 1, \ldots, n\}$ such that $\rho(x) = 0$ if $x$ is a minimal element of $P$, and $\rho(y) = \rho(x) + 1$ if $x < y$ in $P$; $x$ has rank $i$ if $\rho(x) = i$. An $x$-$y$-chain is a saturated chain from $x$ to $y$.

Let $P$ be a finite, bounded, and graded poset. An edge-labelling of $P$ is a function $\lambda : \{(x, y) \in P^2 \mid x < y\} \to Q$, where $Q$ is a totally ordered set. If $\lambda$ is an edge-labelling of $P$ and $x_0 < x_1 < \cdots < x_k$ is a saturated chain, let $\lambda(x_0, x_1, \ldots, x_k) = (\lambda(x_0, x_1), \lambda(x_1, x_2), \ldots, \lambda(x_{k-1}, x_k))$. The chain is said to be increasing if $\lambda(x_{i-1}, x_i) \leq \lambda(x_i, x_{i+1})$ for all $i \in [k - 1]$, and decreasing if $\lambda(x_{i-1}, x_i) > \lambda(x_i, x_{i+1})$ for all $i \in [k - 1]$. An edge-labelling $\lambda$ of $P$ is an EL-labelling if, for all $x < y$ in $P$, there is exactly one increasing $x$-$y$-chain, say $x_0 < x_1 < \cdots < x_k$, and this chain is lexicographically minimal, or lex-minimal, among the $x$-$y$-chains in $P$ (i.e., if $y_0 < y_1 < \cdots < y_k$ is any other $x$-$y$-chain, then $\lambda(x_{j-1}, x_j) < \lambda(y_{j-1}, y_j)$, where $j = \min\{i \in [k] \mid \lambda(x_{i-1}, x_i) \neq \lambda(y_{i-1}, y_i)\}$; this is known as the lexicographic order). If $P$ has an EL-labelling, $P$ is said to be EL-shellable. The reason for this is the following result, due to Björner.

**Theorem C** (11, Theorem 2.3) Let $P$ be a finite, bounded, and graded poset. If $P$ is EL-shellable, then its order complex $\Delta(P)$ is shellable.

For $\sigma \in S_n$ and $(k, l) \in [n]^2$, let $\sigma[k, l] = \{i \leq k \mid \sigma(i) \geq l\}$. The Bruhat order on $S_n$ may be defined as follows (see, e.g., [2, Theorem 2.1.5]):

**Definition 4** Let $\sigma, \tau \in S_n$. Then $\sigma \leq \tau$ if and only if $\sigma[k, l] \leq \tau[k, l]$ for all $(k, l) \in [n]^2$.

Let us turn to involutions in the symmetric group. Here, notation will follow [9]. Let $\sigma \in S_n$. A rise of $\sigma$ is a pair $(i, j) \in [n]^2$ such that $i < j$ and $\sigma(i) > \sigma(j)$. A rise $(i, j)$ is called free if there is no $i < k < j$ such that $\sigma(i) < \sigma(k) < \sigma(j)$. A rise $(i, j)$ is called free if there is no $i < k < j$ such that $\sigma(i) < \sigma(k) < \sigma(j)$. An inversion is a pair $(i, j) \in [n]^2$ such that $i < j$ and $\sigma(i) > \sigma(j)$. An element $i \in [n]$ is a fixed point of $\sigma$ if $\sigma(i) = i$, an exceedance if $\sigma(i) > i$, and a deficiency if $\sigma(i) < i$. Let $\text{inv}(\sigma)$ and $\text{exc}(\sigma)$ denote the number of inversions and exceedances, respectively, of $\sigma$. 

Let \( \sigma \in I_n \). A free rise \((i,j)\) of \( \sigma \) is suitable if it is an \( ff \)-rise (Type 1), an \( fe \)-rise (Type 2), an \( ef \)-rise (Type 3), a non-crossing \( ee \)-rise (Type 4), a crossing \( ee \)-rise (Type 5), or an \( ed \)-rise (Type 6). Here \( fe\), e.g., means that \( i \) is a fixed point of \( \sigma \) while \( j \) is an exceedance, and an \( ee \)-rise is crossing if \( \sigma(i) < j \) and non-crossing otherwise.

The following definition is very important.

**Definition 5** Let \( \sigma \in I_n \) and let \((i,j)\) be a suitable rise of \( \sigma \). We define a new involution \( ct_{(i,j)}(\sigma) \) as follows:

- If \((i,j)\) is of Type 1, then \( ct_{(i,j)}(\sigma) = \sigma(i,j) \).
- If \((i,j)\) is of Type 2, then \( ct_{(i,j)}(\sigma) = \sigma(i,j,\sigma(j)) \).
- If \((i,j)\) is of Type 3, then \( ct_{(i,j)}(\sigma) = \sigma(i,j,\sigma(i)) \).
- If \((i,j)\) is of Type 4, then \( ct_{(i,j)}(\sigma) = \sigma(i,j)(\sigma(i),\sigma(j)) \).
- If \((i,j)\) is of Type 5, then \( ct_{(i,j)}(\sigma) = \sigma(i,j,\sigma(j),\sigma(i)) \).
- If \((i,j)\) is of Type 6, then \( ct_{(i,j)}(\sigma) = \sigma(i,j)(\sigma(i),\sigma(j)) \).

See [9 Table 1] for pictures describing the action of \( ct_{(i,j)} \) on the diagram of \( \sigma \).

Incitti characterised the covering relation in \( I_n \) as follows.

**Lemma 6 ([9 Theorem 5.1])** Let \( \sigma, \tau \in I_n \). Then \( \sigma \triangleright \tau \) in \( I_n \) if and only if \( \tau = ct_{(i,j)}(\sigma) \) for some (necessarily unique) suitable rise \((i,j)\) of \( \sigma \).

If \( \tau = ct_{(i,j)}(\sigma) \) for some suitable rise \((i,j)\) of \( \sigma \), let \( \lambda(\sigma,\tau) = (i,j) \). By Lemma 6, this defines an edge-labelling of \( I_n \) with \( \{(i,j) \in [n]^2 \mid i < j\} \) totally ordered by the lexicographic order, i.e., \((i_1,j_1) < (i_2,j_2)\) if and only if \( i_1 < i_2 \) or \( i_1 = i_2 \) and \( j_1 < j_2 \). Whenever we consider an edge-labelling of \( I_n \), it is this one. If \( \lambda(\sigma,\tau) = (i,j) \), then \((i,j)\) is the label on the cover \( \sigma \triangleright \tau \); \((i,j)\) is a label on a chain if it is the label on some cover of the chain.

Let \( \tau \in I_n \) and let \((i,j)\) be an inversion of \( \tau \). If \((i,j)\) is a suitable rise of some \( \sigma \in I_n \) and \( ct_{(i,j)}(\sigma) = \tau \), then \( \sigma \) is unique, and we write \( \sigma = ict_{(i,j)}(\tau) \).

For \( \sigma < \tau \in I_n \), let \( di(\sigma,\tau) = \min\{i \in [n] \mid \sigma(i) \neq \tau(i)\} \).

We shall need the following results, due to Incitti:

**Lemma 7 ([9 Theorem 5.2])** The poset \( I_n \) is graded with rank function \( \rho \) given by

\[
\rho(\sigma) = \frac{\text{inv}(\sigma) + \text{exc}(\sigma)}{2}.
\]

**Lemma 8 ([9 Theorem 6.2])** Let \( \sigma < \tau \in I_n \). Then there is exactly one increasing \( \sigma-\tau \)-chain, and it is lex-minimal.

**Lemma 9 ([9 Theorem 7.3])** Let \( \sigma < \tau \in I_n \). Then there is exactly one decreasing \( \sigma-\tau \)-chain.

**Remark 1** Since \( ct_{(i,j)}(\sigma)(i) > ct_{(i,j)}(\sigma)(j) \), there is also exactly one “weakly” decreasing \( \sigma-\tau \)-chain. This fact is used in Section [4]
3 Sketch of the proof of the main result

In this section, we prove, sketch the proofs of, or simply state, a number of lemmas and propositions, from which Theorem 1 easily follows.

The strategy for proving that a poset $F_n^A$ is graded is as follows. We first prove that $F_n^A$ has a maximum and that all its minimal elements have the same rank in $I_n$ (see Propositions 11 and 12). We then prove that if $\sigma, \tau \in F_n^A$ then $\sigma \preceq \tau$ in $F_n^A$ if and only if $\sigma \preceq \tau$ in $I_n$ (one implication is obvious). This is done in Lemmas 15, 16, and 17. Since $I_n$ is graded, it thus follows that $F_n^A$ is graded.

In particular, when $F_n^A \in \{F_n^{\leq a}, F_n^{\geq a}\}$, to prove that $\sigma \preceq \tau$ in $I_n$ if $\sigma \preceq \tau$ in $F_n^A$, we assume that $\sigma \npreceq \tau$ in $I_n$, and consider the increasing and the decreasing $\sigma$-$\tau$-chains in $I_n$. We then prove that either the element in the increasing chain that covers $\sigma$, or the element in the decreasing chain that is covered by $\tau$, has to belong to $F_n^A$. This contradicts the fact that $\sigma \preceq \tau$ in $F_n^A$.

To prove that a poset $F_n^A$ is not graded, we consider an interval $[\sigma, \tau]$, and then construct two $\sigma$-$\tau$-chains in $F_n^A$ of different lengths (see Propositions 19 and 20).

Let us first note the following fact:

Lemma 10 For all $n$ and all $A$, $F_n^A$ is graded if and only if $F_n^{A-\{n\}}$ is graded.

Proof: This is obvious if $n \notin A$. Otherwise, deleting the identity permutation gives a bijection between maximal chains in $F_n^A$ of length $k$ and maximal chains in $F_n^{A-\{n\}}$ of length $k - 1$. □

In the next two results, we describe the maximal and minimal elements of $F_n^A$. The proofs are not given here.

Proposition 11 For all $n$ and all $A$, $F_n^A$ has a $\hat{1}$. Furthermore, $\text{inv}(\hat{1}) = \frac{n-a}{2} (n + a - 1)$ and $\text{exc}(\hat{1}) = \frac{n-a}{2}$, where $a = \min A$.

Proposition 12 For all $n$ and all $A$, all minimal elements of $F_n^A$ have rank $(n - \max A)/2$ in $I_n$.

Recall that

$$F_n^{\leq a} = \bigcup_{i \geq 0} F_n^{a-2i}, \quad F_n^{\geq a} = \bigcup_{i \geq 0} F_n^{a+2i}, \quad \text{and} \quad F_n^{a_1:a_2} = F_n^{\geq a_1} \cap F_n^{\leq a_2},$$

where $a_2 = a_1 + 2m$ for some positive integer $m$. Note that $F_n^{a_1:a_2}$ is not defined for $a_1 = a_2$.

The following lemma will eventually allow us to conclude that $F_n^{\leq a}$, $F_n^{\geq a}$, and $F_n^{a_1:a_2}$ are graded.

Lemma 13 If every cover in $F_n^A$ is a cover in $I_n$, then $F_n^A$ is graded.

Proof: This follows from Lemma 7 and Propositions 11 and 12. □

The next lemma is used in the proofs of Lemmas 15, 16, and 17, which, together with Lemma 13, show that $F_n^{\leq a}$, $F_n^{\geq a}$, and $F_n^{a_1:a_2}$ are graded.

Lemma 14 Let $\sigma \prec \tau$ in $I_n$. Then the label $(i,j)$ on any cover in $[\sigma, \tau]$ satisfies $i \geq \text{di}(\sigma, \tau)$.

Proof: Suppose $i < \text{di}(\sigma, \tau)$ for the label $(i,j)$ on $\sigma \prec \pi \leq \tau$. Then $\pi(k) = \tau(k)$ for $k < i$ and $\sigma(i) = \tau(i)$. However, it follows from Definition 5 that $\pi(i) > \sigma(i)$. Hence, $\pi[i, \sigma(i)+1] > \tau[i, \sigma(i)+1]$. By Definition 4, this contradicts the fact that $\pi \leq \tau$. Thus $i \geq \text{di}(\sigma, \tau)$. The result follows by induction. □
Lemma 15 Let \( \sigma \triangleleft \tau \) in \( F_{n}^{\leq a} \). Then \( \sigma \triangleleft \tau \) in \( I_{n} \).

Proof: Assume that \( \sigma \not\triangleleft \tau \) in \( I_{n} \), and let \( C_{I} = \sigma \triangleleft \sigma_{1} \triangleleft \cdots \triangleleft \sigma_{k} \triangleleft \tau \) be the increasing \( \sigma \)-\( \tau \)-chain in \( I_{n} \) and \( C_{D} = \sigma \triangleleft \tau_{k} \triangleleft \cdots \triangleleft \tau_{1} \triangleleft \tau \) the decreasing \( \sigma \)-\( \tau \)-chain in \( I_{n} \). Since \( \sigma \triangleleft \tau \) in \( F_{n}^{\leq a} \), neither \( \sigma \) nor \( \tau \) belongs to \( F_{n}^{\leq a} \).

Let \( h = \operatorname{di}(\sigma, \tau) \), and let \((i_{\sigma}, j_{\sigma})\) and \((i_{\tau}, j_{\tau})\) be the labels on \( \sigma \triangleleft \sigma_{1} \triangleleft \tau_{1} \triangleleft \tau \) the decreasing \( \sigma \)-\( \tau \)-chain in \( I_{n} \). Since \( \sigma \triangleleft \tau \) in \( F_{n}^{\leq a} \), neither \( \sigma_{1} \) nor \( \tau_{1} \) belongs to \( F_{n}^{\leq a} \).

Let \( h = \operatorname{di}(\sigma, \tau) \), and let \((i_{\sigma}, j_{\sigma})\) and \((i_{\tau}, j_{\tau})\) be the labels on \( \sigma \triangleleft \sigma_{1} \triangleleft \tau_{1} \triangleleft \tau \) respectively. Since \( \sigma(h) \not= \tau(h) \), it follows from Lemma 14 that \( h \) is in some label on \( C_{I} \) and some label on \( C_{D} \). Since \( C_{I} \) is increasing, \( i_{\sigma} = h \), and since \( \sigma \not\in F_{n}^{\leq a} \), \( h \) is an exceedance of \( \sigma \) (Type 5). Since \( C_{D} \) is decreasing, \( i_{\tau} = h \), and since \( \tau \not\in F_{n}^{\leq a} \), \( h \) is a fixed point of \( \tau_{1} \) (Type 1). Hence, \( \sigma(h, h + 1) > \tau_{1}[h, h + 1] \). By Definition 4 this contradicts the fact that \( \sigma \triangleleft \tau_{1} \).

Lemma 16 Let \( \sigma \triangleleft \tau \) in \( F_{n}^{\geq a} \). Then \( \sigma \triangleleft \tau \) in \( I_{n} \).

Proof: Assume that \( \sigma \not\triangleleft \tau \) in \( I_{n} \), and let \( C_{I} = \sigma \triangleleft \sigma_{1} \triangleleft \cdots \triangleleft \sigma_{k} \triangleleft \tau \) be the increasing \( \sigma \)-\( \tau \)-chain in \( I_{n} \) and \( C_{D} = \sigma \triangleleft \tau_{k} \triangleleft \cdots \triangleleft \tau_{1} \triangleleft \tau \) the decreasing \( \sigma \)-\( \tau \)-chain in \( I_{n} \). Since \( \sigma \triangleleft \tau \) in \( F_{n}^{\leq a} \), neither \( \sigma \) nor \( \tau \) belongs to \( F_{n}^{\leq a} \).

Let \( h = \operatorname{di}(\sigma, \tau) \), and let \((i_{\sigma}, j_{\sigma})\) and \((i_{\tau}, j_{\tau})\) be the labels on \( \sigma \triangleleft \sigma_{1} \triangleleft \tau_{1} \triangleleft \tau \) respectively. Since \( \sigma(h) \not= \tau(h) \), it follows from Lemma 14 that \( h \) is in some label on \( C_{I} \) and some label on \( C_{D} \). Since \( C_{I} \) is increasing, \( i_{\sigma} = h \), and since \( \sigma \not\in F_{n}^{\leq a} \), \( h \) is a fixed point of \( \sigma \) (Type 1). Since \( C_{D} \) is decreasing, \( i_{\tau} = h \), and since \( \tau \not\in F_{n}^{\leq a} \), \( h \) is an exceedance of \( \tau_{1} \) (Type 5).

Let \( m \) be such that \( h \) is an exceedance of \( \tau_{1}, \ldots, \tau_{m-1} \) and a fixed point of \( \tau_{m} \) (with \( \tau_{k+1} = \sigma \)). Then the labels on \( \tau \triangleleft \tau_{1} \triangleleft \cdots \triangleleft \tau_{m} \) are \( (h, j_{1}), (h, j_{2}), \ldots, (h, j_{m}) \), where \( j_{1} < j_{2} < \cdots < j_{m} \). Since \( \tau_{1} \) is an exceedance of \( \tau_{2} \) but an exceedance of \( \tau_{m-1} \) the cover \( \tau_{m} \triangleleft \tau_{m-1} \) is of Type 5.

Lemma 17 Let \( \sigma \triangleleft \tau \) in \( F_{n}^{\geq1 \geq a} \). Then \( \sigma \triangleleft \tau \) in \( I_{n} \).

The proof, which is omitted here, is largely a combination of the proofs of Lemmas 15 and 16.

Proposition 18 The posets \( F_{n}^{\leq a}, F_{n}^{\geq a}, \) and \( F_{n}^{\geq1 \geq a} \) are graded.

Proof: This follows from Lemmas 15, 15, 16, and 17.

In the following two results, we consider the sets \( A \) for which \( F_{n}^{A} \) is not graded.

Proposition 19 If there is an \( i \in [2, n-4] \) such that \( i \in A \) but \( i-2, i+2 \not\in A \), then \( F_{n}^{A} \) is not graded.

The proof, which is not given here, is similar to, but easier than, the proof Proposition 20.

Proposition 20 If there is an \( i \not\in A \) and a positive integer \( m \) such that \( i-2, i+2m \in A - \{n\} \), then \( F_{n}^{A} \) is not graded.

Proof sketch: We first prove that \( F_{k}^{(0,k-2)} \), where \( k \geq 6 \) is even, is not graded. Let \( \sigma = 12 \cdots (k-2)k(k-1) \) and \( \tau = k3 \cdots (k-1)1 \), and consider the interval \([\sigma, \tau]\). We obtain a \( \sigma \)-\( \tau \)-chain \( C \) in \( I_{k} \) by \( k-2 \) \( fe \)-rises with labels \( (k-2, k-1), (k-3, k-2), \ldots, (1,2) \) (from \( \sigma \) to \( \tau \)). We also obtain a
\(\sigma - \tau\)-chain in \(I_n\) by \((k - 2)/2\) \(ff\)-rises with labels \((1,2), (3,4), \ldots, (k - 3, k - 2)\), followed by \((k - 2)/2\) crossing \(ee\)-rises with labels \((k - 3, k - 1), (k - 5, k - 3), \ldots, (1, 3)\).

Let \(\pi\) be the fixed point-free involution obtained after the \(ff\)-rises. Since each \(ff\)-rise decreases the number of fixed points and \(I_k\) is graded, \((\sigma, \pi) \cap F_{k}^{(0,k-2)} = \emptyset\), and since each crossing \(ee\)-rise increases the number of fixed points and \(I_k\) is graded, \((\pi, \tau) \cap F_{k}^{(0,k-2)} = \emptyset\). Hence, \(C\) is a \(\sigma - \tau\)-chain in \(F_{k}^{(0,k-2)}\) of length \(k - 2\), while \(\sigma < \tau\) is a \(\sigma - \tau\)-chain in \(F_{k}^{(0,k-2)}\) of length 2. Thus \(F_{k}^{(0,k-2)}\) is not graded.

Figure 3 illustrates the situation when \(k = 6\).

Now we have to obtain the right number of fixed points. The details are not given here. \(\square\)

We are now ready to prove our main result:

**Proof of Theorem 1**: The first claim follows from Lemma 10 and Propositions 18, 19, and 20. (It is readily checked that if \(F_{n}^{A-\{n\}}\) does not belong to \(\{\emptyset, F_{n}^{\pi,n}, F_{n}^{\tau,n}, F_{n}^{\pi,\tau,n}\}\), then either there is an \(i \in [2, n - 4]\) such that \(i \in A\) but \(i - 2, i + 2 \notin A\), or there are an \(i \notin A\) and a positive integer \(m\) such that \(i - 2, i + 2m \in A - \{n\}\).) The second claim follows from Lemma 7, Proposition 12, and Lemmas 15, 16, and 17. The third claim follows from the second claim and Proposition 11. \(\square\)

### 4 EL-shellability of \(F_{n}^{0}\)

In this section, we give a new proof of Theorem 8 due to Can, Cherniavsky, and Twelbeck 3. Our proof is largely based on the same main idea as their proof, together with the technique used in the proof of Lemma 15. The proof in 3 goes as follows:

Let \(\sigma < \tau\) in \(F_{n}^{0}\). It follows from, e.g., Theorem 8 and the paragraphs following it, that there exists a \(\sigma - \tau\)-chain in \(I_n\) that is contained in \(F_{n}^{0}\). Let \(C\) be the lex-maximal such chain. The idea of the proof is to show that \(C\) is decreasing. Then, by reversing the lexicographic order on the set \(\{i,j\} \in [n]^{2} | i < j\) (i.e., by letting \((i_1, j_1) < (i_2, j_2)\) if and only if \(i_1 > i_2\), or \(i_1 = i_2\) and \(j_1 > j_2\)), one obtains an edge-labelling of \(F_{n}^{0}\) such that in each interval, there is an increasing \(\sigma - \tau\)-chain which is lex-minimal. By Lemma 9 and the remark following it, this is an EL-labelling of \(F_{n}^{0}\).
We use the same main idea, namely, to show that the decreasing $\sigma$-$\tau$-chain in $I_n$ is contained in $F_n^0$, and then reverse the lexicographic order. However, we give a direct proof of this fact. By using the same technique as in the proof of Lemma [15] we get a very short argument.

**Lemma 21** Let $\sigma < \tau$ in $F_n^0$ and let $C_D = \sigma < \tau_k < \cdots < \sigma_1 < \tau$ be the decreasing $\sigma$-$\tau$-chain in $I_n$, where $k \geq 1$. Then $\tau_1, \ldots, \tau_k \in F_n^0$.

**Proof:** Since the decreasing $\sigma$-$\tau_1$-chain in $I_n$ is $\sigma < \tau_k < \cdots < \tau_2 < \tau_1$, it suffices to prove that $\tau_1 \in F_n^0$.

Let $h = d(\sigma, \tau)$, let $C_I = \sigma < \sigma_1 < \cdots < \sigma_k < \tau$ be the increasing $\sigma$-$\tau$-chain in $I_n$, and let $(i_{\sigma}, j_{\sigma})$ and $(i_{\tau}, j_{\tau})$ be the labels on $\sigma < \sigma_1$ and $\tau_1 < \tau$, respectively. Since $\sigma(h) \neq \tau(h)$, it follows from Lemma [14] that $h$ is in some label on $C_I$ and some label on $C_D$. Since $C_I$ is increasing, $i_{\sigma} = h$, and since $\sigma$ has no fixed points, $h$ is an exceedance of $\sigma$ (Type 4, 5, or 6). Since $C_D$ is decreasing, $i_{\tau} = h$, and were $\tau_1 \notin F_n^0$, $h$ would be a fixed point of $\tau_1$ (Type 1). Hence, by Definition [4] $\tau_1 \in F_n^0$. \hfill \Box

We can now complete the proof of Theorem [B].

**Proof of Theorem [B]:** Let $\sigma < \tau$ in $F_n^0$. By Lemma [21] the decreasing $\sigma$-$\tau$-chain in $I_n$ is contained in $F_n^0$. If we can show that this chain is lex-maximal, then by reversing the lexicographic order and invoking Lemma [9] we are done.

In order to obtain a contradiction, let $C = \sigma_1 < \cdots < \sigma_k$ be the lex-maximal $\sigma$-$\tau$-chain in $I_n$, and assume that it is not decreasing; say that $\lambda(\sigma_1, \sigma_2) \leq \lambda(\sigma_2, \sigma_3)$. By Lemma [8] $\sigma_1 < \sigma_2 < \sigma_3$ is lex-minimal among the $\sigma_1$-$\sigma_3$-chains in $I_n$. Hence, $\sigma_1 < \sigma_2 < \sigma_3 < \cdots < \sigma_k$, where $\sigma_1 < \sigma_2 < \sigma_3$ is the decreasing $\sigma_1$-$\sigma_3$-chain, is lex-larger than $C$, which is a contradiction. \hfill \Box

Is it possible to use the same idea to prove that every interval in $F_n^A \subset I_n$ is EL-shellable for some $A \neq \{0\}$? Unfortunately, the answer is no, since for all $A \neq \{0\}$ (except the trivial cases $A = \emptyset$ and $A = \{n\}$), it is possible to find $\sigma_1 < \tau_1$ and $\sigma_2 < \tau_2$ in $F_n^A$, such that the increasing $\sigma_1$-$\tau_1$-chain and the decreasing $\sigma_2$-$\tau_2$-chain in $I_n$, are of length 2 and are not contained in $F_n^A$.
