Autographa californica nuclear polyhedrosis virus (AcNPV) is a double-stranded-DNA (dsDNA) virus that is pathogenic to insects. AcNPV has long been used as an efficient gene expression vector in insect cells (31, 35). Recently, baculovirus was shown to be capable of infecting various mammalian cells without any replication and of expressing foreign genes under the control of a mammalian promoter (28). Therefore, baculovirus is now recognized as a useful viral vector not only for abundant gene expression in insect cells but also for gene delivery into mammalian cells.

In addition to allowing efficient gene delivery, AcNPV has been shown to stimulate interferon (IFN) production in mammalian cell lines and confer protection from lethal virus infection in mice (2, 12). Furthermore, AcNPV was shown to possess a strong adjuvant activity to promote humoral and cellular immune responses against coadministered antigens, maturation of dendritic cells (DCs), and production of proinflammatory cytokines (IFN-β and IFN-inducible chemokines) in IPS-1-deficient MEFs upon infection with vesicular stomatitis virus, AcNPV produced substantial amounts of the cytokines in IPS-1-deficient MEFs. These results suggest that a novel signaling pathway(s) other than TLR- and IPS-1-dependent MEFS participates in the production of type I IFN in response to AcNPV infection.

The baculovirus Autographa californica nuclear polyhedrosis virus (AcNPV) is an enveloped, double-stranded-DNA (dsDNA) virus that is pathogenic to insects. AcNPV has long been used as an efficient gene expression vector in insect cells (31, 35). Recently, baculovirus was shown to be capable of infecting various mammalian cells without any replication and of expressing foreign genes under the control of a mammalian promoter (28). Therefore, baculovirus is now recognized as a useful viral vector not only for abundant gene expression in insect cells but also for gene delivery into mammalian cells.

DCs, and mouse embryonic fibroblasts (MEFs), was dependent on the RIG-I/MDA5 signaling pathways (23). On the other hand, recent studies have also shown that non-pDC immune cells participate in the production of type I IFN in response to viral infection through TLR-dependent and TLR-independent pathways (9, 34). Viral genomic DNA of adenovirus (38, 53) and herpes simplex virus type 1 (HSV-1) (15) produces type I IFN through both TLR-dependent and -independent pathways. Modified vaccinia virus Ankara has also been shown to induce TLR-independent type I IFN production (46). Furthermore, nonprofessional immune cells, such as fibroblasts, were shown to produce type I IFN upon viral infection through a TLR-independent pathway (25). Infection with intracellular bacteria or introduction of synthetic dsDNA also induces production of type I IFN through a TLR- or an RNA helicase-independent pathway (19), suggesting the existence of a cytosolic DNA-sensing mechanism which stimulates the production of type I IFN (4, 5, 43). These results suggest that genomes of DNA viruses and intracellular bacteria produce type I IFN through a not-yet-identified cytosolic DNA-sensing machinery.

In this study, we have examined the mechanism of production of type I IFN in both pDCs and non-pDCs in response to AcNPV stimulation. The levels of involvement of the TLR or the RNA helicase pathway in the production of type I IFN in response to AcNPV stimulation differed among cell types, and the production was completely dependent on IRF7 in both pDCs and non-pDCs, such as PECs and splenic CD11c<sup>+</sup> DCs, whereas it was dependent on IRF3 in MEFs. These results suggest that AcNPV is capable of producing type I IFN through both TLR-dependent and -independent pathways and might be an ideal tool for elucidating the mechanisms of the induction of type I IFN by DNA in mammalian cells.

**MATERIALS AND METHODS**

**Mice and MEFs.** C57BL<sup>6</sup> mice were purchased from CLEA Japan (Tokyo, Japan). MyD88<sup>-/-</sup>, TLR3<sup>-/-</sup>, TLR7<sup>-/-</sup>, TLR9<sup>-/-</sup>, IFN-α/β receptor (IFNR<sup>-/-</sup>), RIG-I<sup>-/-</sup>, or IFN-γ receptor (IFN-γR<sup>-/-</sup>) mice were obtained from day 12.5 to 13.5 embryos. MEFs were maintained in DMEM (Sigma, St. Louis, MO) supplemented with 10% fetal bovine serum (FBS) and antibiotics. MEFs from mice with double knockout of MyD88 and TRIF, RIG-I, or IPS-1 were described previously (1). Phosphorothioate-stabilized mouse CpG (mCpG) oligonucleotide (<i>G</i>5′-TGAATCCGGAATCG-3′ and 5′-AGGACTAGCCATCCACTGGGTAAAG-3′) was purchased from PBL Biomedical Laboratories (New Brunswick, NJ) and BD PharMingen (San Diego, CA), respectively. To determine the effects of endosomal maturation on cytokine production by infection with AcNPV or transfection of baculoviral DNA, PECs and splenic CD11c<sup>+</sup> DCs were seeded into 96-well plates at a concentration of 2 × 10<sup>4</sup> cells/well and inoculated with AcNPV or transfected with the viral DNA encapsulated in liposomes in the presence or absence of endosomal inhibitors, such as chloroquine. AcNPV (100 μg/mouse) was intraperitoneally inoculated into wild-type mice and mice with knockout of the MyD88, TRIF, IFNR, or IFN-γ gene, and levels of production of IL-12, IL-6, and IFN-α in sera were determined at different time points.

**Quantitative analyses of cytokine mRNA.** MEFs derived from wild-type mice; mice with knockout of the IFRS, IFN-γ, RIG-I, or IFP-1 gene; and mice with double knockout of the MyD88 and TRIF genes were stimulated with AcNPV, VSV, LPS, gp64<sup>Δ</sup>TM, AcNPV DNA, or poly(I:C). At 4 to 8 h posttreatment, total RNA was prepared from the MEFs by using an RNeasy mini kit (Qiagen). First-strand cDNA was synthesized by using a ReverTra Ace kit (Toyobo, Osaka, Japan) and an oligo(dT)<sub>20</sub> primer. Each cDNA was estimated by use of Platinum SYBR green qPCR SuperMix UD (Invitrogen) according to the manufacturer’s protocol. Fluorescent signals were analyzed with an ABI Prism 7000 instrument (Applied Biosystems, Tokyo, Japan). Genomic DNA was quantified by chemiluminescence using a Bio-Rad (Hercules, CA) Gel-Doc (Calyx, Wako, Tokyo, Japan). The recombinant proteins were analyzed by sodium dodecyl sulfate-12.5% polyacrylamide gel electrophoresis under reducing conditions, stained with GelCode Blue stain reagent (Pierce), and detected by immunoblot analysis using antihexahistidine monoclonal antibody (Santa Cruz Biotechnology, Santa Cruz, CA) or antiserum to gp64 (AcV5), kindly provided by P. Faulkner.

**Preparation of PECs and splenic DCs.** To evaluate cytokine production in macrophages in vitro, mice were intraperitoneally injected with 2 ml of 4% thioglycollate (Sigma), and exudation cells were harvested at 3 days posttreatment by peritoneal lavage. Thioglycollate-elicited PECs were seeded into 96-well plates at a concentration of 2 × 10<sup>5</sup> cells/well and treated with various doses of stimuli. After 24 h of incubation, culture supernatants were harvested and analyzed for cytokine production. To prepare splenocytes containing DCs or pDCs, spleen tissue was cut into small fragments and incubated with RPMI 1640 medium containing 400 U/ml collagenase (Wako, Tokyo, Japan) and 15 μg/ml DNase (Sigma) at 37°C for 20 min. For the last 5 min, 5 mM EDTA was added, and single-cell suspensions were prepared after red blood cell lysis. Splenic CD11<sup>+</sup> DCs and pDCs were purified by a magnetic cell sorter system with anti-CD11c and anti-murine plasmacytoid dendritic cell antigen 1 microbeads (Miltenyi Biotec GmbH, Bergisch Gladbach, Germany), respectively, following the manufacturer’s instructions. Enriched cells containing >90% splenic CD11<sup>+</sup> DCs and pDCs were seeded into 96-well plates at a concentration of 2 × 10<sup>5</sup> cells/well.

**Production of cytokines in vitro and in vivo.** Production of IFNs (IFN-α and -β) and proinflammatory cytokines (interleukin-6 [IL-6] and IL-12) in the culture supernatants was determined by the use of enzyme-linked immunosorbent assay (ELISA) kits purchased from PBL Biomedical Laboratories (New Brunswick, NJ) and BD PharMingen (San Diego, CA), respectively. To determine the effects of endosomal maturation on cytokine production by infection with AcNPV or transfection of baculoviral DNA, PECs and splenic CD11c<sup>+</sup> DCs were seeded into 96-well plates at a concentration of 2 × 10<sup>5</sup> cells/well and inoculated with AcNPV or transfected with the viral DNA encapsulated in liposomes in the presence or absence of endosomal inhibitors, such as chloroquine. AcNPV (100 μg/mouse) was intraperitoneally inoculated into wild-type mice and mice with knockout of the MyD88, TRIF, IFNR, or IFN-γ gene, and levels of production of IL-12, IL-6, and IFN-α in sera were determined at different time points.

**RESULTS**

**Involvement of TLR-dependent and -independent pathways in the production of type I IFN by AcNPV in immune cells and in mice.** We have reported previously that AcNPV is capable of producing type I IFN through both TLR-dependent and -independent pathways and might be an ideal tool for elucidating the mechanisms of the induction of type I IFN by DNA in mammalian cells.
of producing type I IFN in PECs and splenic CD11c⁺ DCs through a partially MyD88/TLR9-independent pathway (1). Although many studies of the production of type I IFN upon infection with DNA or RNA viruses have been conducted, the precise mechanisms of IFN production by AcNPV remain unclear. To clarify the mechanisms of induction of type I IFN by AcNPV in more detail, we examined the effect of inhibitors of endosomal maturation on the production of type I IFN by AcNPV in PECs derived from wild-type and MyD88- or TLR9-deficient mice. As shown in Fig. 1A, chloroquine clearly inhibited TLR9- or MyD88-dependent IL-12 production in PECs upon infection with AcNPV in a dose-dependent manner but not in cells from TLR9-deficient mice treated with LPS, probably due to the activation of TLR4 on the plasma membrane. In contrast, AcNPV produces IFN-α and IFN-β through a TLR9-independent and partially MyD88-dependent pathway in PECs, whereas production of type I IFN by AcNPV in PECs was resistant to chloroquine treatment (Fig. 1A). These results indicate that AcNPV produces proinflammatory cytokines and type I IFN in PECs through a TLR-dependent and a TLR-independent pathway, respectively. Furthermore, AcNPV induces type I IFN in PECs through an endocytosis-independent pathway. AcNPV also produced type I IFN in CD11c⁺ DCs through a TLR9-independent and partially MyD88-dependent pathway, as seen with the PECs, whereas type I IFN production in CD11c⁺ DCs by AcNPV was sensitive to chloroquine treatment in a dose-dependent manner (data not shown). The partial impairment of IFN-α production in MyD88-deficient
mice suggests that other TLRs may be involved in IFN production by AcNPV. However, PECs from mice deficient in TLR3 and TLR7, which recognize dsRNA and single-stranded RNA, respectively, exhibited no reduction of IFN-α production upon infection with AcNPV (Fig. 1B). These results suggest that a novel cytoplasmic DNA-sensing mechanism other than TLR3, TLR7, and TLR9 signaling pathways might be involved in the production of type I IFN in PECs upon infection with AcNPV.

Although AcNPV contains a high level of unmethylated CpG DNA comparable to that found in the genomes of *E. coli* and HSV (1), the involvement of a TLR9/MyD88 signal pathway in the production of type I IFN by the AcNPV genome remains unclear. *E. coli* DNA and phosphorothioate-stabilized mCpG oligonucleotides (ODN1668) were capable of producing a large amount of IL-12 in PECs through a TLR9/MyD88-dependent pathway, whereas production of type I IFN was not induced by the ligands (Fig. 1C). Production of IL-12 and IFN-α in PECs transfected with the purified baculoviral DNA was impaired by knockout of the TLR9 or the MyD88 gene, whereas substantial amounts of IFN-β were still produced in PECs derived from MyD88- or TLR9-deficient mice (Fig. 1C). These results suggest that a TLR9/MyD88-independent DNA recognition pathway participates in the production of type I IFN in PECs in response to the AcNPV genome.

pDCs are known as master producers of type I IFN upon virus infection, and IFN production is largely dependent on the TLR signaling pathway (11). IFN-α production in pDCs derived from TLR9- or MyD88-deficient mice was severely impaired in response to AcNPV stimulation (Fig. 1D), suggesting that AcNPV induces IFN-α production in pDCs through a TLR9/MyD88-dependent pathway. Next, to examine the mechanisms of induction of type I IFN by AcNPV in vivo, AcNPV was intraperitoneally inoculated into wild-type and MyD88- or TLR9-deficient mice, and levels of IFN-α and IL-12 production in sera were determined. TLR9- or MyD88-deficient mice exhibited a level of serum IFN-α similar to that of wild-type mice upon infection with AcNPV, whereas IL-12 production in the deficient mice was severely impaired (Fig. 1E). These results suggest that non-pDCs participate in the production of type I IFN through a TLR9/MyD88-independent pathway in response to AcNPV in vivo, in contrast to the TLR9/MyD88-dependent production of proinflammatory cytokines. Collectively, these results indicate that both TLR-dependent and -independent pathways are involved in the production of type I IFN in immune cells, including PECs, CD11c+ DCs, and pDCs, in response to AcNPV.

**IFR7** plays a crucial role in the production of type I IFN by AcNPV in immune cells and in mice. Both IRF3 and IRF7 are required for the production of type I IFN through a classical pathway activated by viral infection (18, 41). Therefore, we examined the involvement of IRF3 and IRF7 in the production of type I IFN in response to AcNPV by using PECs and splenic CD11c+ DCs derived from IRF3- and IRF7-deficient mice (Fig. 2A). IFN-α production in the IRF7-deficient PECs and splenic CD11c+ DCs in response to AcNPV or VSV was impaired, whereas such production was still active in the IRF3-deficient immune cells. IFN-β production in PECs was impaired in the IRF3- or IRF7-deficient mice in response to AcNPV, although significant amounts of IFN-β were produced in the IRF3- or IRF7-deficient PECs upon infection with VSV. In contrast to the PECs, IRF3-deficient splenic CD11c+ DCs produced a level of IFN-β comparable to that in the wild-type cells in response to AcNPV. In response to VSV infection, production of IFN-β in the deficient immune cells was less impaired. Although enhancement of IL-12 production in the IRF3-deficient PECs and splenic CD11c+ DCs in response to AcNPV or VSV was observed, similar levels of IL-12 production were observed in the IRF7-deficient immune cells and in wild-type cells in response to AcNPV or VSV.

There is circumstantial evidence that IRF7 plays a role in the MyD88-dependent production of IFN-α by activating the TLR in pDCs (17, 25). Therefore, we next examined the IFN-α production in pDCs obtained from IRF7-deficient mice. Consistent with the previous observations, IFN-α production in response to AcNPV was completely abolished in the IRF7-deficient pDCs (Fig. 2B). Furthermore, production of IFN-α, but not that of IL-12 and IL-6, in response to AcNPV in IRF7-deficient mice was severely impaired (Fig. 2C). These results suggest that IRF7 plays a crucial role in the production of type I IFN upon infection with AcNPV in the immune cells and in vivo.

**Involvement of the IFN-α signaling pathway in the production of type I IFN by AcNPV.** The many subtypes of IFN-α and IFN-β are released from infected cells and bind to a single IFN-α receptor, and receptor-mediated signal transduction induces the expression of numerous IFN-stimulated genes whose products interfere with viral replication. To determine the involvement of the IFN-α-mediated signal transduction in the induction of the innate immune response by AcNPV infection, production of IFN-α, IFN-β, and IL-12 in PECs and splenic CD11c+ DCs derived from IFN-α-deficient mice after stimulation with AcNPV or poly(I:C) was examined. Production of IFN-α and IFN-β was significantly impaired by AcNPV or poly(I:C) in the IFN-α-deficient PECs and splenic CD11c+ DCs (Fig. 3A and B), whereas IL-12 production in the deficient immune cells was comparable to that in the wild-type cells. In contrast to the in vitro data, production of IFN-α in the sera of IFN-α-deficient mice was still detectable and exhibited a partial impairment at 6 h posttreatment (Fig. 3C). These results suggest that production of type I IFN in vivo in response to AcNPV is regulated mainly by an IFN-α-mediated signal pathway, whereas an IFN-α-independent pathway is additionally involved in the production of type I IFN in response to AcNPV in vivo.

**Envelope glycoprotein gp64 does not participate in the immune activation by AcNPV.** A previous study demonstrated that the recombinant envelope glycoprotein of AcNPV lacking a transmembrane domain (gp64ΔTM) did not produce proinflammatory cytokines or type I IFN in a murine macrophage cell line, RAW264.7 (1). However, the ability of gp64ΔTM to induce an innate immune response in primary mouse immune cells and nonimmune cells has not yet been examined. To determine the involvement of the envelope glycoprotein of AcNPV in immune activation, we prepared a C-terminally six-His-tagged gp64 lacking the transmembrane region (His-gp64ΔTM), as described previously (1), and examined its ability to activate primary mouse cells, such as PECs, splenic CD11c+ DCs, and MEFs. His-gp64ΔTM was purified as a homogeneous band and was clearly detected by anti-His and anti-gp64 antibodies (Fig. 4A). Although infection with
AcNPV produced large amounts of IL-12 and IFN-α in PECs and splenic CD11c+ DCs, only a low level of IL-12 production was detected after infection with His-gp64TM (Fig. 4B). Furthermore, infection with AcNPV resulted in rapid production of IFN-β, inflammatory cytokines, and chemokines, including IL-6, MCP-1, RANTES, and IP-10, in MEFs, in contrast to the low level of production of the cytokines by infection with His-gp64TM (Fig. 4C). These results suggest that the envelope glycoprotein, gp64, does not play an important role in the immune activation by AcNPV.

AcNPV produces IFN-β and IFN-inducible chemokines through a TLR-independent and IRF3-dependent pathway in MEFs. We next examined the involvement of the TLR signaling pathway in immune activation by AcNPV in MEFs. MEFs were isolated from wild-type and MyD88/TRIF double knockout mice, and the production of cytokines after stimulation with AcNPV, VSV, LPS, or poly(I:C) was determined by ELISA and real-time PCR. In the MyD88/TRIF-deficient MEFs, the production of IL-6 was severely impaired in response to AcNPV and LPS, whereas no effect was observed after treatment with VSV or poly(I:C) (Fig. 5A, top). In contrast, the production of IFN-β in MEFs in response to AcNPV, VSV, or poly(I:C) was not affected by knockout of the MyD88/TRIF genes. LPS did not induce IFN-β production in either wild-type or MyD88/TRIF-deficient MEFs (Fig. 5A, bottom). Comparable levels of mRNA of IFN-β and IFN-inducible chemokines, including MCP-1, RANTES, and IP-10, were detected in wild-type and MyD88/TRIF knockout MEFs in response to AcNPV (Fig. 5B). These results suggest that a TLR-dependent pathway participates in the production of proinflammatory cytokines by AcNPV in MEFs, as seen with the immune cells, while AcNPV produces IFN-β and IFN-inducible chemokines in MEFs through a TLR-independent pathway.

Next, to determine the involvement of IRF3 and IRF7 in the immune activation in MEFs by AcNPV, wild-type and IRF3- or IRF7-deficient MEFs were treated with AcNPV, LPS, or VSV, and the production of cytokines was determined by ELISA and real-time PCR. Production of IL-6 in IRF3 or IRF7 knockout MEFs after treatment with AcNPV, VSV, or LPS was comparable to that in wild-type MEFs (Fig. 5C, top). In contrast, production of IFN-β was impaired in IRF3- and IRF7-deficient MEFs in response to AcNPV and VSV, respectively, while LPS induced no IFN production in either type of
MEF (Fig. 5C, bottom). Although robust transcription of IFN-β and IFN-inducible chemokines in response to AcNPV was detected in wild-type and IRF7-deficient MEFs, transcription of the genes in response to AcNPV was severely impaired in IRF3-deficient MEFs (Fig. 5D). These results indicate that AcNPV induces the production of IFN-β and IFN-inducible chemokines through a TLR-independent and IRF3-dependent pathway in MEFs, in contrast to the TLR-dependent and IRF3/IRF7-independent production of IL-6.

AcNPV induces antiviral status in MEFs through an IRF3-dependent pathway. To further examine the involvement of IRF3 in the induction of antiviral status in MEFs in response to AcNPV, wild-type and IRF3-deficient MEFs were transfected with the baculoviral DNA, and the mRNAs of the cytokines were measured. Transcription of IFN-β, IFN-α1, MCP-1, RANTES, and IP-10, but not that of IL-6, was impaired in IRF3-deficient MEFs upon transfection with baculoviral DNA (Fig. 6A).

To determine the involvement of endosomal maturation in the immune activation by AcNPV, the effect of chloroquine on the production of IFN-β and IL-6 in response to AcNPV or LPS was examined. Pretreatment with chloroquine reduced the secretion of IFN-β and IL-6 in MEFs in a dose-dependent manner in response to AcNPV infection but exhibited no effect on IL-6 production in MEFs by LPS treatment (Fig. 6B), suggesting that the impairment of IFN-β and IL-6 production was not due to the cytotoxicity of chloroquine. These results indicate that endosomal maturation is required for the induction of the innate immune response by AcNPV in MEFs.

Next, to determine the antiviral effects of the immune acti-
Involvement of a TLR- and RIG-I/IPS-1-independent signaling pathway in immune activation by AcNPV. TLR3 has been shown to recognize viral dsRNA as well as a synthetic dsRNA analogue, poly(I:C), in the intracellular compartment. Recently, RIG-I and MDA5 have been identified as TLR-independent cytoplasmic RNA detectors and shown to induce type I IFN production through an adaptor molecule, IPS-1, that localizes in mitochondria (26, 36, 42, 47). To examine the involvement of TLR-independent cytoplasmic DNA-sensing machinery in the immune activation by AcNPV, as seen in the recognition of intracellular RNA, the production of type I IFN and IFN-inducible chemokines in PECs and splenic CD11c+ DCs derived from RIG-I-, MDA5-, or IPS-1-deficient mice was examined. Type I IFN production in PECs and splenic CD11c+ DCs in response to VSV and poly(I:C) was impaired by knockout of IPS-1, whereas AcNPV produced a significant amount of the IFNs in the IPS-1 knockout immune cells (Fig. 7A). Furthermore, IFN production in the immune cells in response to VSV was abrogated by knockout of the RIG-I gene but not by knockout of the MDA5 gene; however, AcNPV produced significant amounts of the IFNs in the RIG-I or MDA5 knockout immune cells (data not shown).

Next, to determine whether IPS-1 is involved in the production of type I IFN and IFN-inducible chemokines in MEFs in response to AcNPV, production of the cytokines in the IPS-1-deficient MEFs in response to VSV or AcNPV was examined (Fig. 7B). Production of IFN-β, IL-6, MCP-1, RANTES, and IP-10 was severely impaired in IPS-1-deficient MEFs upon VSV infection, whereas AcNPV produced substantial amounts of the cytokines in the IPS-1-deficient MEFs in spite of a slight reduction in IFN-β and IL-6 production (Fig. 7B). Similarly, production of the IFN-inducible chemokines in MEFs infected with VSV, but not with AcNPV, was also severely impaired by knockout of the RIG-I gene (data not shown). Collectively, these results suggest that a novel TLR- and RIG-I/IPS-1-independent signaling pathway(s) participated in the production of type I IFN and the IFN-inducible chemokines in both immunocompetent cells and MEFs in response to AcNPV infection.

**DISCUSSION**

Recent progress has been made in the identification of receptors, signal transduction molecules, and transcription factors that are required for the induction of type I IFN in cells upon infection with RNA and DNA viruses, as well as for the robust IFN production in pDCs, suggesting the presence of multiple signaling pathways for type I IFN induction (17, 23, 25). Production of type I IFN was shown to be induced through a number of different pathways in a cell-type-specific manner upon infection with HSV (40), although the precise mechanisms involved in sensing the foreign DNA of microorganisms remain largely unknown. In this study, we have examined the molecular mechanisms of type I IFN induction by AcNPV infection both in professional immune cells, including pDCs,
PECs, and splenic CD11c⁺ DCs, and in nonimmune cells and raised the possibility of the involvement of a novel TLR- and IPS-1-independent pathway in the production of type I IFN in vitro as well as in vivo in response to AcNPV infection.

The frequency of bioactive CpG motifs capable of inducing immune activation through a TLR9-dependent pathway in the AcNPV genome was similar to that in E. coli and HSV and was significantly higher than that in entomopoxvirus (1, 51). Furthermore, it was shown that HSV and murine cytomegalovirus produce inflammatory cytokines and type I IFN through both TLR9-dependent and -independent pathways (7, 15, 29, 32, 44). Recently, it was also reported that adenovirus DNA produced IL-6 and IFN-α through an entirely TLR/MyD88-independent pathway in non-pDCs (53), although the presence of the CpG motifs in the adenoviral genome has not yet been determined. The current model of TLR9 activation by viral DNA is as follows. The virus particles are internalized into cells and degraded within the endocytic vesicles, and the digested viral genome subsequently activates TLR9 localized in the endosomal compartments. Treatment with inhibitors for endosomal maturation or acidification efficiently inhibits TLR7 and TLR9 activation by viral RNA and DNA, respectively (8, 32, 33). Interestingly, the production of type I IFN in PECs upon infection with AcNPV was resistant to pretreatment with endocytosis inhibitors, suggesting that the cytoplasmic recognition of AcNPV by TLR-independent immune sensors may be required for type I IFN production in PECs. The purified AcNPV DNA encapsulated in liposomes induced the produc-
tion of type I IFN through both TLR9/MyD88-dependent and -independent pathways in PECs. These results indicate that the genomic DNA of AcNPV is recognized by at least two different pathways, TLR9-dependent endosomal recognition and TLR9-independent cytoplasmic recognition, and that type I IFN production by AcNPV is totally dependent on the latter process. However, the precise mechanisms of the immune activation of immunocompetent cells by AcNPV DNA through a TLR-independent pathway remain unknown. Therefore, further studies are needed to determine the molecular mechanisms underlying the type I IFN production through a TLR-independent cytoplasmic sensor for baculovirus DNA.

FIG. 6. AcNPV induces antiviral status in MEFs through an IRF3-dependent pathway. (A) MEFs (3 × 10⁵ cells/well) prepared from wild-type and IRF3-deficient mice were transfected with AcNPV DNA (25 μg/ml). Total RNA was extracted at the indicated time points, and the expression of mRNA of IFN-β, IFN-α1, MCP-1, RANTES, IL-6, and IP-10 was determined by real-time PCR. (B) MEFs (2 × 10⁶ cells/well) prepared from wild-type mice were stimulated with AcNPV (10 μg/ml) or LPS (10 μg/ml) in the presence of the indicated concentrations of chloroquine. After 24 h of incubation, production of IL-6 and IFN-β in culture supernatants was determined by ELISA. (C) MEFs (2 × 10⁶ cells/well) prepared from wild-type and IRF3-deficient mice were incubated with AcNPV (0.016 μg/ml to 2 μg/ml) or poly(I:C) (0.2 μg/ml to 25 μg/ml). After 24 h of incubation, cells were washed extensively with warm medium and infected with VSV (GLPLF mutant, MOI of 0.1). Cell viability was determined at 24 h postinfection by crystal violet staining and quantitated by spectroscopy. Values are plotted as means from the triplicate wells. Data are shown as means ± standard deviations. (E) Microscopic observation of MEFs from wild-type mice, showing the antiviral status against VSV infection by the treatment with AcNPV or poly(I:C) in a dose-dependent manner. PC, infected cells; Mock, mock-infected cells. Samples are shown at a magnification of ×40.
A novel TLR-independent cytosolic surveillance system for transfected dsDNA that elicits type I IFN induction through a TANK binding kinase 1 (TBK1)/IkB kinase-related kinase (IKKi)/IRF3 pathway has been shown to exist (19, 43). Our preliminary data also indicate that type I IFN production was severely reduced in TBK1-deficient MEFs in response to AcNPV and insufficient to protect cells from VSV infection (data not shown), suggesting the involvement of TBK1 in AcNPV-induced immune activation. Recently, a cytoplasmic recognition receptor, DAI (DNA-dependent activator of IRFs), was shown to be activated by dsDNA from a variety of sources and to produce type I IFN through an IRF3 and probably IRF7 pathway (45). However, there are conflicting reports suggesting a lack of impairment of type I IFN production in DAI knockout mice and DAI knockdown murine macrophages or MEFs in response to dsDNA of synthetic B-form DNA and from bacteria (4, 20). In this study, we have shown that splenic CD11c⁺ DCs derived from IRF3-deficient mice produced a level of type I IFN compatible with that in wild-type mice in response to AcNPV, in contrast to the lack of IFN-β production in the PECs derived from the IRF3-deficient mice. More recently, two groups reported the identification of a membrane protein, termed mitochondrial mediator of IRF3 activation (MITA) or stimulator of IFN genes (STING), that activates IRF3 to induce a type I IFN response to viral infection (21, 52). Although both groups described slightly different characterizations of MITA, or STING, in terms of localization and signal transduction, both groups exhibited the opinion that MITA or STING plays a critical role in type I IFN production by B-form DNA. Although DAI-mediated type I IFN production was more

**FIG. 7.** Role of IPS-1 in immune activation by AcNPV. (A) PECs and splenic CD11c⁺ DCs (2 × 10⁵ cells/well) prepared from wild-type and IPS-1-deficient mice were stimulated with AcNPV (10 μg/ml), VSV (NCP mutant, MOI of 0.1), or poly(I:C) (pIC) (50 μg/ml). After 24 h of incubation, production of IFN-α and IFN-β in culture supernatants was determined by ELISA. (B) MEFs (3 × 10⁵ cells/well) prepared from wild-type and IPS-1-deficient mice were stimulated with AcNPV (10 μg/ml) or VSV (NCP mutant, MOI of 0.1). Total RNA was extracted at the indicated time points, and the expression of mRNA of IFN-β, MCP-1, RANTES, IL-6, and IP-10 was determined by real-time PCR. Data are shown as the means ± standard deviations.
dependent on IRF3 than on IRF7, the cytoplasmic DNA sensors, including DAI and MITA or STING, may participate in the induction of type I IFN upon infection with AcNPV.

In the cytoplasm, RIG-I and MDA5 are critically involved in the recognition of dsRNA, and the adaptor molecule IPS-1 interacts with RIG-I and MDA5 to facilitate TBK1- and IKK-mediated IRF3 and IRF7 activation, which leads to termination of the replication of RNA viruses through the helicase function. In addition, RIG-I has been shown to discriminate viral RNAs from the vast number and variety of cellular RNAs by recognizing a terminal 5’ triphosphate, but not 5’ OH or a 5’ methylguanosine cap (37, 39). In this study, both RIG-I and IPS-1-deficient MEFs but not immune competent cells partially impaired the production of IFN-β and IL-6, but not that of MCP-1, RANTES, and IP-10, in response to AcNPV, suggesting the possible generation of dsRNA in MEFs upon infection with AcNPV in spite of the lack of replication. Although there is no evidence for the functional expression of the viral proteins, transcription of immediate-early genes of baculovirus was detected in HeLa and BHK cells upon infection with AcNPV by DNA microarray analysis (10) and in HEK293 cells and rat primary Schwann cells upon infection with Bombyx mori NPV by reverse transcription-PCR (27). These reports are consistent with our observations that the RIG-I/IPS-1 pathway partially participates in type I IFN induction by AcNPV infection in MEFs.

We have shown previously that an intranasal inoculation of AcNPV induces protective immunity from a lethal challenge of influenza A virus in mice (2) and that AcNPV produces type I IFN in immune cells of mice via a TLR9/MyD88-independent pathway (1). Our present studies further confirmed that AcNPV induces a strong antiviral immunity through a TLR-pathway (1). Interferon-stimulated genes in mammalian cells does not alter their transcriptional and differentiating potential in human hematopoietic progenitor cells. Nature 434:772–777.
