Abstract

This paper contains the Weyl formula for the counting function of the interior transmission problem when the latter is parameter elliptic. Branching billiard trajectories are constructed, and the second term of the Weyl asymptotics is estimated from above under some conditions on the set of periodic billiard trajectories.

1. Interior transmission eigenvalues

Let $\mathcal{O} \in \mathbb{R}^d$ be an open bounded domain with $C^\infty$ boundary $\partial \mathcal{O}$. The classical Weyl formula

$$N(\lambda) \sim \frac{V(\mathcal{O})\omega_d}{(2\pi)^d} \lambda^{d/2}, \quad \lambda \to \infty,$$

(1)

for the counting function $N(\lambda)$ (number of eigenvalues whose absolute values do not exceed $\lambda$) is well known for the Dirichlet or Neumann Laplacian in $\mathcal{O}$. Here, $V(\mathcal{O})$ is the volume of the domain and $\omega_d$ is the volume of the unit ball in $\mathbb{R}^d$. This paper concerns the Weyl formula for the interior transmission eigenvalues (ITE), which were introduced by Kirsch in [16] in connection with an inverse scattering problem for the reduced wave equation and further studied by Colton and Monk [6]. The anisotropic interior transmission problem (discussed below) was introduced in [7]; see the review [8] for more references.

Let us recall the definition of ITE. The values of $\lambda \in \mathbb{C}$ for which the following problem

$$-\Delta u - \lambda u = 0, \quad x \in \mathcal{O}, \quad u \in H^2(\mathcal{O}),$$

(2a)

$$-\nabla A \nabla v - \lambda n(x)v = 0, \quad x \in \mathcal{O}, \quad v \in H^2(\mathcal{O}),$$

(2b)

$$u - v = 0, \quad x \in \partial \mathcal{O},$$

(2c)

$$\frac{\partial u}{\partial \nu} - \frac{\partial v}{\partial \nu_A} = 0, \quad x \in \partial \mathcal{O},$$

(2d)

for $A \in C(\overline{\mathcal{O}})$, $\nu$ and $\nu_A$ the outer unit normal to $\partial \mathcal{O}$ and $\partial \mathcal{O}_A$, respectively, are called the interior transmission eigenvalues (ITE).
has a non-trivial solution are called the interior transmission eigenvalues. Here, $H^2(O)$ is the Sobolev space, $A(x), x \in \overline{O}$, is a smooth symmetric elliptic ($A = A' > 0$) matrix with real-valued entries, $n(x)$ is a smooth function, $\nu$ is the outward normal to $\partial O$ and the co-normal derivative is defined as follows:

$$\frac{\partial}{\partial \nu} v = v \cdot A \nabla v.$$ 

We will mostly be concerned with the cases $d = 2, 3$, but all the results below can be automatically carried over to any dimension $d$.

There are many papers on the Weyl formula for general elliptic boundary value problems (see review [1] for references). The particular feature of the problem under consideration is that it is not symmetric. The formally conjugate problem has different boundary conditions:

$$u + v = 0, \quad x \in \partial O,$$

$$\frac{\partial u}{\partial \nu} + \frac{\partial v}{\partial \nu} = 0, \quad x \in \partial O. \quad (4)$$

The spectrum of the problem (2)–(3) is not always discrete. Examples when the eigenvalues fill the whole complex plane can be found in [17]. It was also shown there that ITE form a discrete set when the problem is parameter elliptic. Conditions for parameter ellipticity were also described in [17], and they will be formulated below in the case of real $A$ and $n$. This paper contains a justification of the Weyl formula for ITE when the problem (2)–(3) is parameter elliptic. In particular, this implies that the set of ITE is infinite for general parameter-elliptic problems. The infiniteness of the set of ITE was known in many cases; see [3, 4] and references therein. When $A = \mu I$, some estimates on $N(\lambda)$ for ITE can be found in [20, 13]. Before we proceed with the main result on the Weyl formula, we would like to show that ITE play the same role for the transmission scattering problem as the eigenvalues of the Dirichlet or Neumann Laplacian play for the scattering by an obstacle with the corresponding (Dirichlet or Neumann) boundary conditions.

A connection between the counting function $N(\lambda)$ for the Dirichlet or Neumann Laplacian and the total scattering phase (which is defined as $-\arg \det S(k)$, where $S(k)$ is the scattering matrix) was established in 1978; see [18, 15]. It was shown that

$$-\frac{1}{2\pi} \arg \det S(k) = N(\lambda)(1 + O(\lambda^{-\varepsilon})), \quad \varepsilon > 0, \lambda = k^2 \to \infty.$$ 

This formula suggests that $N(\lambda)$ can perhaps be interpreted as the rotation number of the scattering phase (number of rotations of $\exp(i \arg \det S(k))$ on the unit circle when $k \to \infty$). At present, there is a deeper understanding of the relation between $N(\lambda)$ and the rotation number.

Recall that the operator $S(k), k > 0,$ is unitary and its eigenvalues $\zeta = \zeta_j(k)$ belong to the unit circle. Consider the following two conditions.

(A) $-k^2$ is an eigenvalue of the Dirichlet or Neumann Laplacian.

(B) $\zeta = 1$ is an eigenvalue of $S$-matrix ($S = S(k)$) for the scattering problem with the same boundary condition and $k > 0$.

It is easy to see that B implies A. Indeed, the unitary matrix $S(k)$ has the form $S(k) = I + \frac{ik}{\mu} F$, where $F$ is the integral operator on $L^2(S^{d-1})$ ($S^{d-1}$ is the unit sphere) whose kernel is the scattering amplitude. If $S\mu(\theta) = \mu(\theta), \theta \in S^{d-1}$, then $F\mu = 0$. Let $\psi(k, \omega, x) = e^{ik(\omega, x)} + \psi_{sc}, \omega \in S^{d-1}$, be the solution of the scattering problem. Consider the function $u(k, x) = \int_{S^{d-1}} \psi(\mu(\omega)) dS_{\mu}$. The function $u$ satisfies the homogeneous boundary condition since $\psi$ satisfies it. Since $F\mu = 0$, the outgoing wave $\int_{S^{d-1}} \psi(\mu(\omega)) dS_{\mu}$ has zero amplitude, and therefore, it is equal to zero identically. Thus, $u(k, x) = \int_{S^{d-1}} e^{ik(\omega, x)} \mu(\omega) dS_{\mu}$. 

Obviously, this function satisfies the Helmholtz equation in the whole space, i.e. $u$ is an eigenfunction of the interior problem with the eigenvalue $-k^2$.

This implication from $B$ to $A$ was first noted in papers on inverse scattering problem (see [5]) if slightly different terminology was used: injectivity of the far-field operator $F$ implies $A$. In terms of $S$-matrix, it can be found in [9].

The inverse implication (from $A$ to $B$) holds in the case of a ball, but not for general domains, see [10]. However, for general domains $O$, $B$ implies $A$ in a weaker sense: $-k_0^2$ is an eigenvalue of the Dirichlet Laplacian if and only if there exists an analytic in $k \in (k_0 - \delta, k_0), \delta > 0$, eigenvalue $z = z_j(k)$ of the $S$-matrix such that

$$\lim_{k \to k_0 - 0} \arg z_j(k) = 2\pi + 0. \quad (5)$$

In connection with the last relation, let us note that the eigenvalues $z = [z_j(k)]$ of the $S$-matrix $S(k)$ form an analytic manifold while $z \neq 1$. The point $z = 1$ is an essential point of the spectrum of the operator $S(k)$ (limiting point for the set of eigenvalues) and the structure of the manifold in a neighborhood of this point is much more complicated. In particular, it may happen that an eigenvalue approaches $z = 1$ as $k \to k_0$, but $z = 1$ is not an eigenvalue of $S(k_0)$. It is also essential that we have $k \to k_0 - 0$ in (5), but not $k \to k_0 + 0$.

The study of the connection between properties $A$ and $B$ was initiated by Doron and Smilansky [9]. Relation (5) was justified by Eckmann and Pillett in [10] in the case of the Dirichlet boundary condition. A similar result for the Neumann boundary condition is given in [11].

All the relations between the Dirichlet/Neumann problem and the scattering problem mentioned above can be easily reformulated for ITE and the (exterior) transmission scattering problem. The latter problem is stated as follows:

$$-\Delta u - \lambda u = 0, \quad x \in \mathbb{R}^d \setminus \Omega, \quad u = e^{ik(x,\omega)} + \psi_{\infty}(x, k, \omega), \quad (6)$$

$$u - v = 0, \quad x \in \partial\Omega,$$

$$\frac{\partial u}{\partial n} - \frac{\partial v}{\partial n} = 0, \quad x \in \partial\Omega, \quad (7)$$

where $\lambda = k^2$, $\psi_{\infty}$ satisfies the radiation conditions:

$$\psi_{\infty} = f(k, \theta, \omega) \frac{e^{ikr}}{r^{d-1/2}} + O\left(\frac{1}{r^{d+1/2}}\right), \quad \theta = \frac{x}{r}, \quad r = |x| \to \infty.$$ 

**Proposition 1.1.** If $z = 1$ is an eigenvalue of the scattering matrix $S_r(k), k > 0$, for the transmission scattering problem (6)–(7), then $k^2$ is one of the ITE.

The proof of this statement is the same as in the case of the Dirichlet or Neumann boundary conditions. The inverse statement is also valid for the transmission problem when $\Omega$ is a ball, $A = aM$, $a$ and $n$ are constant. We believe that the result on the weak implication from $B$ to $A$ also holds for the transmission problem (for arbitrary domains $\Omega$), but it has not been proved yet.

Let us recall conditions on $A, n$ which guarantee the parameter ellipticity of interior transmission problem (2)–(3). In this paper, we assume that $A$ and $n$ are real valued. Let us fix an arbitrary point $x^0 \in \partial\Omega$ and choose a new orthonormal basis $\{e_j\}, 1 \leq j \leq d$, centered at the point $x^0$ with $e_j = v$, where $v$ is the normal to the boundary at the point $x^0$. The vectors $e_1, \ldots, e_{d-1}$ belong to the tangent plane to $\partial\Omega$ at the point $x_0$. Let $y$ be the local coordinates defined by the basis $\{e_j\}$, and let $C = C(x^0)$ be the transfer matrix, i.e. $y = C(x - x^0)$.
We fix the point \( x = x^0 \) in equations (2) and (3) and rewrite the problem in the local coordinates \( y \). Then, we obtain the following problem with constant coefficients in the half-space \( y_d > 0 \):
\[
-\Delta_x u - k^2 u = 0, \quad y_d > 0,
\]
\[
-\nabla_x \tilde{A} \nabla_x v - k^2 n(x^0) v = 0, \quad y_d > 0,
\]
\[
u - v = 0, \quad y_d = 0,
\]
\[
\frac{\partial u}{\partial y_d} - \frac{\partial v}{\partial y_d} = 0, \quad y_d = 0.
\]
(8)

Here
\[
\tilde{A} = \tilde{A}(x^0) = CA(x^0)C^*.
\]

The entries of the matrix \( a_{ij} \) are equal to \( a_{ij} = e_j \cdot A(x^0)e_i \). The co-normal derivative in the boundary condition equals \( e_d \cdot \tilde{A} \nabla_y \).

The following result can be extracted from [17].

**Theorem 2.1.** Let \( A(x) > 0, n(x) > 0 \) for \( x \in \Omega \) and the following conditions hold for all \( x^0 \in \partial \Omega \): if \( d = 2 \), then
\[
a_{2,2} n(x^0) - 1 \neq 0 \quad \text{and} \quad \det A(x^0) \neq 1, \quad x^0 \in \partial \Omega;
\]
if \( d = 3 \), then
\[
a_{3,3} n(x^0) - 1 \neq 0 \quad \text{and} \quad \det \left( \begin{array}{ccc} a_{1,1} & -a_{1,2} & a_{1,3} \\ a_{2,1} & -a_{2,2} & a_{2,3} \\ a_{3,1} & -a_{3,2} & a_{3,3} \end{array} \right) > 0, \quad x^0 \in \partial \Omega.
\]

Then, the interior transmission problem (2)–(3) is parameter elliptic for \( \lambda \) in any sector of the complex \( \lambda \)-plane that does not contain either of the rays \( R_+ \) and \( R_- \). Its eigenvalues form a discrete set.

Moreover, if \( \sigma = 1 \), then the problem is parameter elliptic also on \( R_- \). Here
\[
\sigma = \text{sgn}[a_{2,2} n(x^0) - 1)(\det A(x^0) - 1)], \quad x^0 \in \partial \Omega,
\]
if \( d = 2 \). If \( d = 3 \), then \( \sigma = 1 \) when the matrix
\[
\begin{pmatrix}
0 & a_{2,2} - (a_{1,3})^2 - 1 & a_{2,3} - (a_{2,3})^2 - 1 \\
0 & a_{3,3} - (a_{1,3})^2 - 1 & a_{3,2} - (a_{2,3})^2 - 1 \\
0 & a_{3,3} - (a_{1,3})^2 - 1 & a_{3,2} - (a_{2,3})^2 - 1
\end{pmatrix}, \quad x^0 \in \partial \Omega,
\]
is sign-definite and \( \sigma = -1 \) otherwise.

2. Weyl asymptotics and branching billiards

Let us split the set \( \{ \lambda \}, \lambda \in \mathbb{C} \), of ITE into two subsets \( \{ \lambda^+ \} \) and \( \{ \lambda^- \} \), where \( \text{Re}\lambda^+ > 0 \), \( \text{Re}\lambda^- < 0 \). We enumerate the ITE \( \lambda^+ \) and \( \lambda^- \) in increasing order of \( |\lambda_n| \) and denote by \( N^+(t) \) and \( N^-(t) \) the counting functions for \( \{ \lambda^+_n \} \) and \( \{ \lambda^-_n \} \), respectively. Similarly, we enumerate the whole set of the ITE in increasing order of \( |\lambda_n| \) and denote by \( N(t) \) the counting functions for \( \{ \lambda_n \} \).

**Theorem 2.1.** Let assumptions of theorem 1.2 hold (with arbitrary \( \sigma = \pm 1 \)). Then, we have the following.

1. There is at most a finite number of ITE inside any sector of complex \( \lambda \)-plane, which does not contain either of the rays \( R_+ \) and \( R_- \).
Theorem 1.2 holds when both \( \alpha \neq 1 \) and \( \alpha_n \neq 1 \). Formula (11) in this case takes the form
\[
\alpha = \frac{\omega_d}{(2\pi)^d} V(O) \left( 1 + \left( \frac{n}{a} \right)^{d/2} \right).
\]
(3) If \( \sigma = 1 \), then the set \( \{ \lambda_n^+ \} \) is finite. If \( \sigma = -1 \), then there exists \( M > 0 \) such that
\[
N^-(t) < Mt, \quad t \to \infty, \quad d = 2; \quad N^-(t) < Mt \ln t, \quad t \to \infty, \quad d = 3.
\]

Remark. If \( n(x) = a, A(x) = al \), where \( a > 0, a \neq 1 \), then the substitution \( u - v = u_1, au - v = v_1 \) reduces the problem (2)–(3) to the Dirichlet problem for \( u_1 \) and the Neumann problem for \( v_1 \). Hence, in this case, the set \( \{ \lambda_n \} \) coincides with the union of the Dirichlet and Neumann Laplacians.

Proof. The first statement of the theorem and the first part of the last statement (concerning \( \sigma = 1 \)) are immediate consequences of the parameter ellipticity of the problem established in theorem 1.2. The second statement follows from theorem 1.2 and results obtained in [2], where the main term of the Weyl asymptotics is justified for non-symmetric parameter-elliptic system if the eigenvalues of the main symbol \( A \) of the system belong to \( \mathbb{R}^+ \). Formula (10) holds in this case with
\[
\alpha = \frac{1}{(2\pi)^d} \int_{O} \int_{\mathbb{R}^d} N(1, x, \xi) \, dx \, d\xi,
\]
where \( N(1, r, \xi) \) is the number of eigenvalues of \( A \) whose absolute values do not exceed 1. In our case,
\[
A = \begin{pmatrix}
\xi^2 & 0 \\
0 & \frac{1}{\rho(x)} \xi^2 A(x) \xi
\end{pmatrix},
\]
and
\[
\alpha = \frac{1}{(2\pi)^d} \int_{O} \, dx \left( \int_{|\xi| < 1} + \int_{|\xi| > n(x)} \right) \, d\xi,
\]
which implies (11).

The part of the third statement concerning the case \( \sigma = -1 \) is a consequence of theorem 2 from [2]. The latter theorem estimates the number of the eigenvalues of the problem in a sector, which does not contain the eigenvalues of the principle symbol of the operator. □

It is well known that the remainder term in the classical Weyl asymptotics depends on the set of the closed billiard trajectories (periodic trajectories of the corresponding Hamiltonian system). The second term of the asymptotics was justified by Ivrii [14] for boundary value problems for the Laplacian under the condition that the set of periodic trajectories has zero measure. Vasiliev [21] and Safarov [19] extended this result to the case of self-adjoint elliptic system where the billiard trajectories are not defined uniquely after a ray hits the boundary (see figure 1(a)). We cannot use the latter results directly since the problem (2)–(3) is not symmetric,
but we will combine these results with the theory of $s$-numbers to obtain an estimate for the second term of the asymptotics from above. Let us describe the branching trajectories for our problem.

Consider two Hamiltonian flows $G_i, i = 1, 2$, with Hamiltonians

\[ h_1(x, \xi) = |\xi|, \quad h_2(x, \xi) = \sqrt{\frac{1}{n(x)} \xi^t A(x) \xi}, \quad x \in \mathcal{O}, \xi \in \mathbb{R}^d (= T'(\mathcal{O})). \]  

(12)

We assume that $h_1(x, \xi) \neq h_2(x, \xi), \, \forall x \in \mathcal{O}, \xi \in \mathbb{R}^d \setminus \{0\}$, which is equivalent to the following.

**Assumption 2.2.** Matrix $\frac{1}{n(x)} A = \text{Id}$ is positive definite or negative definite when $x \in \overline{\mathcal{O}}$.

When a ray that corresponds to one of these Hamiltonians comes to the boundary $\partial \mathcal{O}$, it creates two reflected rays. One of the reflection angles corresponds to the ‘billiard law’: reflection angle is equal to the incident angle. This ray corresponds to the same Hamiltonian as the Hamiltonian of the incident ray. The second reflection ray is defined by Snell’s law. One can determine both reflected rays as follows. If the Hamiltonian of the incident ray is equal to 1 (it is constant along the trajectory), then the directions of the reflected rays are defined by the relations $h_1 = h_2 = 1$ at the point of reflection (and it may happen that one of these equations does not have a solution in which case there is only one reflected ray).

One needs to work with branching trajectories in order to construct quasi-modes (approximate solutions of the problem). A branching trajectory splits every time when it has a chance to split after the reflection from the boundary. After the initial Hamiltonian $h_{i_0}$ (to start the trajectory) is chosen, the branching trajectory is defined uniquely by its initial data $(y, \eta), \, y \in \mathcal{O}, \eta \in \mathbb{R}^d, \, h_{i_0}(y, \eta) = 1$. The initial data form a $(2d - 1)$-dimensional manifold. For our purpose (an estimate on the second term in the Weyl asymptotics), we need another object, billiard trajectories. These trajectories $(x'_t, \xi'_t)$, $t \geq 0$, do not split. The point moves according to one of the Hamiltonian flows and the Hamiltonian can be changed after each reflection from the boundary. Thus, each initial data usually defines infinitely many billiard trajectories.
A billiard trajectory is called a dead-end trajectory if the ray touches the boundary or there are infinitely many reflections on a finite time interval.

**Assumption 2.3.** The measure of the dead-end trajectories (i.e. the \((2d-1)\)-Lebesgue measure of the set of initial data for the dead-end trajectories) is zero.

Consider a periodic billiard trajectory with a period \(T\) and initial data \((y_0, \eta_0)\). This trajectory is called absolutely periodic if for each \((y, \eta)\) in a \(\rho\)-neighborhood of \((y_0, \eta_0)\) a billiard trajectory \((x', \xi')\), \(t \geq 0\), with the initial data \((y, \eta)\) can be chosen in such a way (by repeating the same pattern of reflections) that the trajectory at time \(t = T\) is located in \(O(\rho^\alpha)\), \(\rho \to 0\), neighborhood of the starting point \((y, \eta)\). The latter means that the function \((x', \xi') - (y, \eta)\) has a zero of infinite order at the point \((y_0, \eta_0)\). The initial data \((y_0, \eta_0)\) is called absolutely periodic if at least one absolutely periodic trajectory has this data.

**Assumption 2.4.** \((2d-1)\)-Lebesgue measure of absolutely periodic data is zero.

**Theorem 2.5.** Let the assumptions of theorem 1.2 and assumptions 2.2–2.4 hold. Then, there is a constant \(C\) such that
\[
N(t) \leq \alpha d/2 + Ct^{(d-1)/2}, \quad t \to \infty, \tag{13}
\]
where \(\alpha\) is defined in (11).

**Remark.** Assumption 2.4 can be weakened, see [19].

**Proof.** Denote by \(L_n^2\) the weighted space \(L^2(O) \times L^2(O)\) with the weight that corresponds to the following scalar product:
\[
(u_1, v_1) \cdot (u_2, v_2) = \int_O u_1 \overline{u_2} \, dx + \int_O n(x) v_1 \overline{v_2} \, dx. \tag{14}
\]
Consider the following operator \(L\) in \(L_n^2\) that corresponds to the problem (2)–(3): the mapping \(L\) is defined by
\[
L(u, v) = (-\Delta u, -\frac{1}{n(x)} \nabla A(x) \nabla v), \tag{15}
\]
and the domain \(D_L\) consists of vectors \((u, v)\), \(u, v \in H^2(O)\), such that \(u, v\) satisfy (7). The operator \(L^*\), adjoint to \(L\) with respect to the scalar product (14), can be obtained from \(L\) if we replace the minus signs in both relations in (7) by the plus signs.

Let us fix a real \(\gamma\) that is not an ITE, i.e. the operators \((L - \gamma I)\) and \((L^* - \gamma I)\) are invertible. Consider the operator \(M = (L - \gamma I)^* (L - \gamma I)\) defined on \((u, v), u, v \in H^2(O)\), such that \((u, v) \in D_L, (L - \gamma)(u, v) \in D_L\). The operator \(M\) in \(L_n^2\) with the domain \(D_M\) described above is self-adjoint. One can rewrite the equation \(Mz = \lambda z, z = (u, v)\), in the form of the boundary value problem
\[
(-\Delta - \gamma)^2 u = \lambda u, \quad x \in O, \tag{16}
\]
\[
\left(-\frac{1}{n(x)} \nabla A \nabla - \gamma\right)^2 v = \lambda v, \quad x \in O, \tag{17}
\]
\[
u - u = 0, \quad x \in \partial O, \tag{18}
\]
\[
\nabla u - \frac{\partial u}{\partial n} = 0, \quad x \in \partial O, \tag{19}
\]
\[
\nabla v + \frac{\partial v}{\partial n} = 0, \quad x \in \partial O, \tag{20}
\]
If the assumptions of theorem 1.2 hold, then problem (16)–(17) is elliptic. Indeed, one can check that the Shapiro–Lopatinskii condition for the problem (16)–(17) coincides with the ones for the problem (6)–(7). Another option is to note that the standard elliptic a priori estimates are valid for the solutions of inhomogeneous problem (16)–(17) with inhomogeneities in (16) (since they are valid for operators \((L - \gamma I)\) and \((L^* - \gamma I)\)) and the latter implies the ellipticity of the boundary value problem. Since the problem (16)–(17) is symmetric, we can apply the results of Vassiliev [21, theorem 1.2] and Safarov [19, theorem 1.1], which provide an estimate on the second term of the Weyl asymptotics for symmetric elliptic systems. Namely, it follows that if the assumptions of theorem 1.2 and assumptions 2.2–2.4 hold, then

\[ N(t) = a t^4 + C t^3 + o(t^3), \quad t \to \infty, \tag{18} \]

where \(N(t)\) is the counting function for the operator \((L - \gamma I)^* (L - \gamma I)\) and \(a\) is defined in (11). The operators \([(L - \gamma I)^* (L - \gamma I)]^{-1}
\) and \((L - \gamma I)^{-1}\) are compact, and therefore (e.g., see [12, lemma 3.3])

\[ |\lambda_n((L - \gamma I)^{-1})|^2 \leq \lambda_n([(L - \gamma I)^* (L - \gamma I)]^{-1}), \tag{19} \]

where the eigenvalues \(\lambda_n\) are enumerated in the order of the decay of \(|\lambda_n|\) (contrary to the eigenvalues of operators \(M\) or \(L\) for which \(|\lambda_n| \to \infty\) as \(n \to \infty\)). Inequality (19) implies that

\[ |\lambda_n((L - \gamma I))|^2 \geq \lambda_n([(L - \gamma I)^* (L - \gamma I))], \]

and this together with (18) justify the statement of the theorem.

3. Strongly periodic branching trajectories

Consider again the branching billiard trajectories of the ITE problem. In the previous section, we considered periodic billiard trajectories where the point moves (after hitting the boundary) along one of the possible reflected rays. Now, we assume that the trajectory splits every time when it has a chance to split. We will call such a trajectory strongly periodic branching billiard trajectory if it consists of a finite number of segments (see figure 1(a)). Under some additional condition on the optical lengths of some parts of the trajectory, one can use these trajectories to construct quasi-modes for the ITE problem, i.e., to construct functions that almost (as \(k = k_n \to \infty\)) satisfy the equations and boundary conditions of the ITE problem.

One also can construct quasi-modes for the exterior transmission problem. The corresponding billiard trajectories are defined by the Hamiltonian flow outside of the obstacle with the Hamiltonian \(h_1(x, \xi) = |\xi|\) and the Hamiltonian flow inside of the obstacle with the Hamiltonian \(h_2(x, \xi) = \sqrt{\sum_{\alpha} A(x) \xi}\). After hitting the boundary, each ray splits into reflected and refracted parts. Such a trajectory is called periodic if it consists of a finite number of segments (exterior rays can be semi-infinite, see figures 1(b) and 2).

While the periodic trajectories of the exterior problem may not be related to strongly periodic trajectories of the interior problem (figure 2), each strongly periodic branching trajectory of the interior problem always define a corresponding trajectory of the exterior problem. In order to define such an exterior trajectory, one needs to replace each segment of the interior trajectory, which corresponds to the Hamiltonian \(h_1(x, \xi) = |\xi|\), by its complement on the line containing this segment (see figure 1). One also can extend to \(R^d \setminus O\) the parts of the interior quasi-mode, which correspond to \(h_1\), and then we omit the interior parts of the quasi-mode related to \(h_1\). This will provide a quasi-mode of the exterior problem that has the following property. Its exterior part can be smoothly extended inside of the obstacle as a solution of the Helmholtz equation in the whole space (where the extension is the omitted part of the interior mode). The latter is an important feature in the relation between the ITE and
Figure 2. Periodic branching trajectories of the exterior transmission problem that are not related to the periodic branching trajectories of the interior problem. There is only one incident ray in (a) and three incident rays in (b).

the eigenvalues of the $S$-matrix. In particular, this feature provides an alternative proof that property B implies property A that is discussed in the first section.

Acknowledgments

The work of EL was supported by FEDER funds through COMPETE—Operational Programme Factors of Competitiveness (‘Programa Operacional Factores de Competitividade’) and by Portuguese funds through the Center for Research and Development in Mathematics and Applications, University of Aveiro, and the Portuguese Foundation for Science and Technology (FCT—Fundação para a Ciência e a Tecnologia), under project PEst-C/MAT/UI4106/2011 with COMPETE number FCOMP-01-0124-FEDER-022690 and under the FCT research project PTDC/MAT/113470/2009. The work of BV was partially supported by the NSF grant DMS-1008132. The authors are very grateful to F Cakoni, D Colton, B Gutkin, H Haddar, V Ivrii, A Kirsch, Yu Safarov and D Vassiliev for useful discussions.
