Sorafenib is one of the few effective first-line drugs approved for the treatment of advanced hepatocellular carcinoma (HCC). However, the development of drug resistance is common among individuals with HCC. Recent evidence indicated that the anticancer activity of sorafenib mainly relies on the induction of ferroptosis. Furthermore, in our study, genes that suppress ferroptosis, especially GPX4 and DHODH, were enriched in sorafenib-resistant cells and primary tissues and were associated with poor prognosis of HCC patients who received sorafenib treatment. Therefore, a new ferroptosis inducer comprising a multiplex small interfering RNA (multi-siRNA) capable of simultaneously silencing GPX4 and DHODH was created. Then, exosomes with high multi-siRNA loading and HCC-specific targeting were established by fusing the SP94 peptide and the N-terminal RNA recognition motif (RRM) of U1-A with the exosomal membrane protein Lamp2b. The results from the in vitro and in vivo experiments indicate that this tumor-targeting nano-delivery system (ExoSP94-lamp2b-RRM multi-siRNA) could enhance sorafenib-induced ferroptosis and overcome sorafenib resistance. Taken together, HCC-targeted exosomes (ExoSP94-Lamp2b-RRM) could specifically deliver multi-siRNA to HCC tissues, enhance sorafenib-induced ferroptosis by silencing GPX4 and DHODH expression and consequently increase HCC sensitivity to sorafenib, which opens a new avenue for clinically overcoming sorafenib resistance from the perspective of ferroptosis.

Keywords: hepatocellular carcinoma, resistance, sorafenib, engineered exosome, ferroptosis

INTRODUCTION

Hepatocellular carcinoma (HCC) was ranked as the sixth most commonly diagnosed cancer and the fourth leading cause of cancer-related death worldwide in 2018 (1, 2). In the early stages of HCC, curative treatment can be achieved with tumor ablation, resection, or liver transplantation (3). However, the majority of HCC patients are already in the middle or late stages at the time of
Ferroptosis is a recently discovered form of programmed cell death characterized by iron-dependent accumulation of lipid peroxides to lethal amounts (5). A growing amount of evidence indicates that ferroptosis can be induced by inhibiting cystine/glutamate transporter (system x_c^-) activity, downregulating GPX4 or DHODH expression, and accumulating reactive oxygen species (ROS) (6). Recent reports have shown that sorafenib can induce ferroptosis by inhibiting system x_c^- (7). Moreover, numerous studies suggest that the anticancer activity of sorafenib mainly relies on inducing ferroptosis (5, 8–11). Therefore, targeting constituents of ferroptosis might be a promising strategy to increase sorafenib efficacy and overcome sorafenib resistance.

Herein, we first found that ferroptosis suppressor genes, especially GPX4 and DHODH, are enriched in sorafenib-resistant cells and primary tissues from patients and are associated with poor prognosis of HCC patients who receive sorafenib treatment. Then, we created a novel ferroptosis inducer comprising a multiplex small interfering RNA (multi-siRNA) suitable for simultaneously silencing GPX4 and DHODH. Then, exosomes (ExoSP94-lamp2b-RRM) with high tumor targeting ability and high multi-siRNA loading efficacy were constructed to deliver the multi-siRNA cargo. Using in vitro and in vivo models, we demonstrated that this tumor-targeting nanodrug (ExoSP94-lamp2b-RRM-multi-siRNA) could enhance sorafenib-induced ferroptosis and overcome sorafenib resistance, suggesting that it is a promising therapeutic strategy for treating sorafenib-resistant HCC.

MATERIALS AND METHODS

Antibodies and Inhibitors

The antibodies used targeted the following proteins (dilutions used are included):

- GAPDH (CW0101: immunoblotting, 1:1000) from CWBIOTECH; F-actin (40734ES75: immunofluorescence, 1:100) from YEASEN; U1A (10212: immunoblotting, 1:500) from Proteintech; CD63 (67605-1-lg: immunoblotting, 1:5000) from Proteintech; CD9 (60232-1-lg: immunoblotting, 1:5000) from Proteintech; TSG101 (14497-1-AP: immunoblotting, 1:1000) from Proteintech; GPX4 (67763-1-Ig: immunoblotting, 1:5000; IHC, 1:1000) from Proteintech; and DHODH (14877-1-AP: immunoblotting, 1:2000; IHC, 1:100) from Proteintech.

The inhibitors used are as follows:

- Sorafenib (HY-10201: 10 μM for the in vitro assay and 30 mg/kg for the in vivo assay) and Ferrostatin-1 (HY-100579: 60 nM for the in vitro assay), and ferrostatin-1 (HY-100579: 5 mg/kg, intraperitoneal injection for the in vivo assay) were obtained from MedChem Express.

Cell Lines and Culture

The HepG-2 and HEK-293T cell lines were obtained from the Type Culture Collection of the Chinese Academy of Sciences (Shanghai, China). These cell lines were authenticated by the analysis of short tandem repeat (STR) profiles, and all of them matched those of the standard cell lines in the DSMZ data bank. These cells tested negative for cross-contamination of other human cells and mycoplasma contamination. The sorafenib-resistant HepG-2 cell line (HepG-2R) was generated by continuous treatment of HepG2 cells with sorafenib up to 10 μM and maintained as previously described (12). HepG-2, HepG-2R and HEK-293T cells were cultured in DMEM containing 10% fetal bovine serum and 1% penicillin-streptomycin.

Plasmid Construction

Briefly, the sequences for SP94 peptide (SFIHHPTPIPL), the CDS sequences of Lamp2b and the CDS sequences of the N-terminal RNA recognition motif (RRM) of U1-A were orderly arranged from N-terminal to C-terminal. Then the sequence encoding the above fusion protein was digested with BamHI-XhoI and cloned into pcDNA3.1(+) vector. The clones were confirmed by DNA sequencing and stored for the following experiments.

Exosome Purification

For exosome isolation from HEK-293T cells, cells were transfected with control or SP94-Lamp2b-RRM expressing plasmids with Lipofectamine3000. 12 h later, cells were further cultured in DMEM with 10% exosome-depleted FBS (ultracentrifugation at 120,000 ×g for 16 h) for 24–36 h. Then, the culture medium was precleared by centrifugation at 5000×g for 15 min and then at 10000×g for 20 min. Exosomes were isolated by ultracentrifugation at 110000×g for 70 min at 4°C and washed in PBS using the same centrifugation conditions. The concentration of exosomes was determined by measuring total exosomal protein using a Pierce BCA Protein Assay Kit (Thermo Scientific, USA) according to the manufacturer’s instructions. NanoSight and transmission electron microscopy were used to determine the size distribution, concentration and morphology of the exosomes. For siRNA loading experiments, 100 nM corresponding siRNAs were transfected with Lipofectamine 3000. Twenty-four hours later, the cells were further cultured in DMEM with 10% exosome-depleted FBS for another 24 h, followed by exosome isolation.

Transmission Electron Microscope Assay

Cells were collected and fixed with 2.5% glutaraldehyde. Subsequently, cells were postfixed in 2% tetroxide and dehydrated through a series of gradient ethanol solutions. Samples were embedded in epoxy resin, cut into thin slices, and placed onto a nickel grid. Images were acquired using a Tecnai G2 Spirit transmission electron microscope (Thermo Fisher).
**Intracellular ROS Measurements**
A lipid ROS assay was performed as described previously. Briefly, cells were incubated with PBS containing 10 μM DCFDA dye in a cell culture incubator for 30 min. Cells were then collected and washed twice with PBS followed by resuspension in 200 μl of PBS. ROS levels were analyzed using a Beckman CytoFLEX system through the FITC channel.

**Detection of Malondialdehyde (MDA)**
Analysis of lipid peroxidation was assessed by quantifying the MDA concentration in cell lysates using a Lipid Peroxidation MDA Assay Kit (S0131, Beyotime) in accordance with the manufacturer’s instructions.

**Animal Study**
Six-week-old, male, athymic BALB/c nude mice were used. All animal experiments were carried out under protocols approved by the Animal Care and Use Committee of Fourth Military Medical University.

For in vivo tracking of exosomes, purified exosomes with the indicated modifications were labeled with the fluorescent dye DiR at a final concentration of 8 μM (Invitrogen). Labeled exosomes were collected by ultracentrifugation after washing with saline and stored in saline before use. Mice were injected with labeled exosomes (100 μg at the protein level in 100 μl) via tail vein injection. Mice were subjected to fluorescent living imaging 6 h after injection with an in vivo imaging system (IVIS lumina II).

For orthotopic implantation, six-week-old male nude mice were anesthetized with 3% (w/v) pentobarbital sodium by intraperitoneal injection. Then, 2×10^6 sorafenib-resistant HepG-2 cells were anesthetized with 3% (w/v) pentobarbital sodium by intraperitoneal injection. Two weeks after inoculation, mice were subjected to imaging 6 h after injection with an in vivo imaging system (IVIS lumina II). Two weeks after inoculation, mice were randomized to each group and began to receive different treatments. In the sorafenib treatment group, sorafenib (30 mg/kg) was given every 3 days. In the sorafenib and exosome combination treatment group, sorafenib was administered at the same dose, and 100 μg of the indicated exosomes (at the protein level) was injected via the tail vein 24 h after every sorafenib administration. At the end of the experiment, mice were sacrificed. Tumor bearing liver tissues and the main organs were collected for the following experiments.

**Immunohistochemistry**
This experiment was performed as previously described (13). Briefly, sections (4 μm thick) of paraffin-embedded samples were deparaffinized and rehydrated in a graded series of ethanol. After inactivation of endogenous peroxidase activity with 3% H2O2 in methanol for 10 min, the sections were washed three times in PBS and blocked with goat serum for 20 min. Then, they were incubated with primary antibodies in a humid container at 4°C overnight. After the addition of the PowerVision™ complex, tissue sections were incubated at 37°C for 20 min followed by treatment with DAB. PBS in place of primary antibody was used as a negative control.

**Statistical Analysis**
The data are presented as the mean ± s.e.m. from at least three independent experiments. Statistical analysis was performed using GraphPad Prism software. A random number table was used to randomize the mice into control and treatment groups. The numbers of mice were determined on the basis of our pretests and previous experience with similar experiments. A value of P<0.05 was considered statistically significant. The statistical tests were two-sided.

**RESULTS**

**Suppressed Ferroptotic Activity During Sorafenib Treatment Is Associated With Compromised Therapeutic Efficiency**
To confirm whether sorafenib could induce ferroptosis in HCC cells, we performed a CCK-8 assay. Our data showed that sorafenib-mediated cell death in the human HCC cell line HepG-2 was blocked by ferrostatin-1 (a ferroptosis inhibitor) (Figure 1A, Figure S1A). The accumulation of reactive oxygen species (ROS) and lipid peroxidation are key events in ferroptosis (14); thus, we analyzed the levels of ROS and the end products of lipid peroxidation (i.e., MDA) in HepG-2 cells. The results indicated that sorafenib increased the levels of ROS and MDA in HepG-2 cells (Figures 1B, C). Apart from ferroptosis-suppressing agents, numerous genes have been identified as key ferroptosis suppressors. For example, glutathione peroxidase 4 (GPX4) resides in the center of a network that functions to prevent the accumulation of lipid hydroperoxides, thereby strongly suppressing ferroptosis (15). Interestingly, we constructed a ferroptosis suppressor gene signature and discovered that ferroptosis suppressor genes were enriched in sorafenib-resistant cells and primary tissues from HCC patients (Figure S1D, Figure S1B). Moreover, the results indicated that the high expression level of the ferroptosis suppressor gene signature was associated with poor prognosis of HCC patients who received sorafenib treatment (Figure 1E, Figure S1C). Therefore, the results suggest that suppressed ferroptotic activity is associated with sorafenib resistance.

**Gene-Silencing Activities of the Multi-siRNA Against GPX4 and DHODH**
The above data suggest that silencing key ferroptosis suppressor genes increases the therapeutic effect of sorafenib. Among the ferroptosis suppressor genes, GPX4 and DHODH can directly remove the dangerous products of iron-dependent lipid peroxidation and consequently protect the cell membrane from damage; when GPX4 and DHODH expression and/or function are dysregulated, ferroptosis ensues (16, 17). Moreover, we found that the expression of GPX4 and DHODH was upregulated in sorafenib-resistant patients (Figures 2A, B) and associated with
poor prognosis of HCC patients who received sorafenib treatment (Figures 2C, D). Meanwhile, GPX4 and DHODH expression was upregulated in sorafenib-resistant HCC cell line (HepG-2R) (Figure 2E). In light of these findings, we sought to interfere with the expression and function of these two genes at the same time. First, siRNAs targeting the human GPX4 gene and human DHODH gene were designed and screened to determine their effectiveness. As shown in Figures 2F, G and Figures S2A, B, si-GPX#1 and si-DHODH#1 were the most effective siRNAs in knocking down their respective proteins. Then, we designed a multi-siRNA containing the sequences corresponding to si-GPX4#1 and si-DHODH#1; the sequence “AUUGCAC” was used as a linker to connect si-GPX4#1 to si-DHODH#1. The results showed that this multi-siRNA could simultaneously suppress GPX4 and DHODH expression (Figure 2H).

**Preparation and Characterization of SP94-Lamp2b-RRM Fusion Protein-Engineered Exosomes**

Exosomes have been considered a good siRNA delivery vehicle to reduce drug resistance (18). However, low cargo encapsulation efficiency and the lack of cell-type specific targeting remain major hurdles for their potential clinical application. Recently, some RNA-binding proteins have been shown to significantly promote exosomal miRNA cargo loading via interaction with common short sequence motifs present in miRNAs (19). Therefore, we hypothesized that fusion of specific RNA-binding proteins with the exosomal membrane proteins can increase the loading efficiency of the desired RNAs. We fused the N-terminal RNA recognition motif (RRM) of U1-A with the C-terminus of Lamp2b (exosomal
surface protein) (Figures 3A, B). U1-A can bind the highly conserved sequence “AUUGCAC” in RNA via its N-terminal RRM (20). SP94 (protein sequence, SFSIIHTPILPL), is a novel peptide that has been reported to specifically bind to HCC cells (21). Therefore, we fused SP94 with the N-terminus of Lamp2b to enhance the tumor-targeting ability of the engineered exosomes (Figures 3A, B). The recombinant vector produced abundant expression of the fusion protein in transfected cells (Figure 3C). As the engineered SP94-Lamp2b-RRM fusion protein could express on exosomes (Figure 3D), we analyzed the binding ability of these exosomes to HCC cells. The results showed that exosomes derived from HEK-293T cells transfected with SP94-Lamp2b-RRM could bind strongly to HCC cells (Figure 3E), indicating that the SP94-Lamp2b-RRM fusion protein was incorporated into exosomes. In addition, specific exosome markers (CD63, TSG101 and CD9) were
detected in the purified samples, while the Golgi marker GM130 was barely detectable (Figure 3F). Nanoparticle tracking analysis (NTA) revealed that the exosomes were similar in number and had a similar size distribution between the groups (Figure 3G). Transmission electron microscopy (TEM) confirmed that the purified exosomes exhibited a typical round-shaped vesicular morphology and were within the appropriate size range (Figure 3H).
Efficient Therapeutic Cargo Encapsulation Into SP94-Lamp2b-RRM Fusion-Protein-Engineered Exosomes

Next, we explored whether the engineered SP94-Lamp2b-RRM fusion protein could promote RNA loading during exosome biogenesis. First, HEK-293T cells overexpressing the SP94-Lamp2b-RRM fusion protein were transfected with 100 nM corresponding FITC-tagged multi-siRNA (Figure 4A). Then, an equal number of exosomes from each group was evaluated by flow cytometry. The results showed that a higher amount of multi-siRNA containing the RRM recognition motif “AUUGCAC” could be sorted into exosomes compared to that of multi-siRNA#2 without the RRM binding sequence (Figure 4B). HEK-293T cells were then cocultured with HepG-2 cells (Figure 4C). Images from the confocal microscope showed a higher level of multi-siRNA containing the RRM “AUUGCAC” in HepG-2 cells (Figure 4D). Consistent
with this finding, exosomes derived from HEK-293T cells transfected with the multi-siRNA containing the “AUUGCAU” sequence could significantly suppress the expression of GPX4 and DHODH in HCC cells (Figure 4E). These results suggest that the SP94-Lamp2b-RRM fusion protein promotes the exosomal loading of the “AUUGCAU” sequence linked to the multi-siRNA via RNA-protein interactions.

**SP94-Lamp2b-RRM-Functionalized Exosomes Could Overcome Sorafenib-Induced Ferroptosis in HCC Cells**

To investigate whether ExoSP94-Lamp2b-RRM can bind to HCC cells, blank exosomes or ExoSP94-Lamp2b-RRM were labeled with DiO and added to sorafenib-resistant HepG-2 cell cultures. Confocal assay showed that green fluorescence appeared within 15 min and intensified over time (up to 60 min) in the SP94-Lamp2b-RRM-functionalized exosomes treated group. By contrast, relatively low level of green fluorescence was observed in control exosomes treated cells up to 60 min, confirming the targeting ability of SP94-Lamp2b-RRM-functionalized exosomes to HCC cells (Figures 5A, B). Then, we treated sorafenib-resistant HepG-2 cells with exosomes (ExoSP94-Lamp2b-RRM, multi-siRNA#1). The results showed that ExoSP94-Lamp2b-RRM, multi-siRNA#1 could significantly enhance the effect of sorafenib (Figure 5C). Then, we further measured ROS and lipid peroxidation levels, which are the primary drivers of ferroptosis. The results showed that treatment with ExoSP94-Lamp2b-RRM, multi-siRNA#1 significantly increased ROS and MDA levels in sorafenib-resistant cells (Figures 5D, E). In addition to biochemical analyses, TEM was used to observe morphological changes. ExoSP94-Lamp2b-RRM, multi-siRNA#1 treated cells displayed diminished or vanished mitochondrial cristae and condensed mitochondrial membrane densities compared to ExoSP94-Lamp2b-RRM, scramble-treated cells (Figure 5F). Moreover, we also found that ExoSP94-Lamp2b-RRM, multi-siRNA#1 could enhance sorafenib-induced ferroptotic cell death (Figure 5G). Taken together, these results suggested that ExoSP94-Lamp2b-RRM, multi-siRNA#1 could enhance sorafenib-induced ferroptosis in HCC cells by silencing the expression of GPX4 and DHODH.

**SP94-Lamp2b-RRM-Functionalized Exosomes Could Efficiently Target Hepatocellular Carcinoma In Vivo**

To confirm whether SP94-Lamp2b-RRM-functionalized exosomes could target HCC in vivo, we tracked the distribution of DiR-labeled exosomes. First, we established an orthotopic liver injection model and observed that SP94-Lamp2b-RRM-functionalized exosomes were mainly distributed to the liver (Figures 6A–C). Meanwhile, SP94-Lamp2b-RRM-functionalized exosomes could target HCC (Figures 6A–C). Next, sorafenib-resistant HepG-2 cells were subcutaneously inoculated into the left backs of mice. In the subcutaneous HCC model, we found that SP94-Lamp2b-RRM-functionalized exosomes were mainly distributed in the liver and subcutaneous tumor tissues (Figure 6D, Figure S3A). The results from the different HCC models suggest that the SP94 targeting peptide dramatically enhances the ability of exosomes to bind HCC cells and tissues.

**Therapeutic Effects of Cotreatment With SP94-Lamp2b-RRM-Functionalized Exosomes and Sorafenib in an HCC Mouse Model**

Next, we explored the therapeutic effect of SP94-Lamp2b-RRM-functionalized exosomes combined with sorafenib in vivo. While the tumors of mice treated with sorafenib and ExoSP94-Lamp2b-RRM containing scramble multi-siRNA grew rapidly, those of mice treated with sorafenib and ExoSP94-Lamp2b-RRM containing multi-siRNA#1 were significantly reduced after 21 days of treatment (Figures 7A–C). However, the effect of sorafenib and ExoSP94-Lamp2b-RRM containing multi-siRNA#1 on inhibiting tumor growth was diminished when cells were treated with the ferroptosis inhibitor ferrostatin-1 (Figures 7A–C). Similarly, mice from the sorafenib and ExoSP94-Lamp2b-RRM containing multi-siRNA#1 cotreatment group had a longer life expectancy than did mice from the sorafenib and ExoSP94-Lamp2b-RRM containing scramble multi-siRNA treatment group (Figure 7D). To examine the knockdown efficiency in each group, GPX4 and DHODH expression in primary tumor lesions was investigated by immunohistochemistry. The results showed that multi-siRNA#1 could significantly suppress GPX4 and DHODH expression in vivo (Figure 7E). Taken together, these results suggested that ExoSP94-Lamp2b-RRM, multi-siRNA#1 could overcome sorafenib resistance in vivo by silencing the ferroptosis suppressor genes GPX4 and DHODH.

**Systemic Toxicity Evaluation**

To evaluate the systemic toxicity of ExoSP94-Lamp2b-RRM, exosomes containing scramble or multi-siRNA#1 were injected into nude mice via tail vein. There was no significant difference in the body weights of mice in the two groups (Figure S4A). In addition, compared to the control group, the ExoSP94-Lamp2b-RRM group showed relatively normal tissue structure and morphology (Figure 8). These results indicate that there was no obvious adverse effect after treatment with ExoSP94-Lamp2b-RRM.

**DISCUSSION**

Our study demonstrated that sorafenib could induce ferroptosis in HCC cells, which is in line with the literature stating that the anticancer activity of sorafenib mainly relies on the induction of ferroptosis. What’s more, we found that the expression of ferroptosis suppressor genes, especially GPX4 and DHODH, was enriched in sorafenib-resistant HCC cells and patient samples, which suggests that suppressed ferroptotic activity is associated with compromised therapeutic efficiency of sorafenib. Thus, precise elimination of ferroptosis suppressor genes might be a new promising strategy to enhance sorafenib efficacy and improve patient prognosis.
Ferroptosis is a form of regulated cell death that is induced by excessive lipid peroxide accumulation in cellular membranes (22–24). Cells have developed at least two major defensive arms to detoxify lipid peroxides: GPX4 and DHODH. Consequently, disabling one arm forces cells to be more dependent on the other. For example, inhibition of either DHODH or GPX4 alone did not induce ferroptosis in HT-1080 cells, which is likely due to the relatively high endogenous expression of GPX4 and DHODH (25);
Interestingly, a GPX4 inhibitor combined with a DHODH inhibitor could synergistically suppress HT-1080 tumor growth. Similarly, in our study, the sorafenib-resistant cells and tissue samples exhibited high levels of GPX4 and DHODH expression. Therefore, disabling both arms might better enhance sorafenib-induced ferroptosis. Here, we created a multi-siRNA that can simultaneously knock down GPX4 and DHODH in vitro and in vivo. To our knowledge, this is the first ferroptosis inducer that can directly target two genes. Additionally, this novel construct provides a new approach for the clinical treatment of sorafenib-resistant cancer.

Because of their intrinsic nature, exosomes are biocompatible with the host immune system and have an innate ability to protect and transport small RNAs and other critical molecules across biological barriers in vivo; they have been increasingly recognized as promising vehicles to deliver siRNA in vivo (26, 27). At present, the most common way to load nucleic acids into exosomes is via electroporation or direct encapsulation in donor cells (28); however, these methods have relatively low loading efficiencies. Meanwhile, in vitro loading of naked siRNAs into exosomes by electroporation could cause extensive siRNA aggregation and significantly reduce the level of bioactive siRNAs (29). Thus, there is an urgent need to develop a strategy for efficient loading of nucleic acids, especially siRNA. Recently, research conducted by our laboratory and others have observed that some RNA-binding...
proteins can efficiently sort miRNAs and other RNAs into exosomes via protein-RNA interactions (30, 31). In light of these data, we hypothesized that fusion of an exosomal membrane protein with a specific RNA-binding protein would increase the loading efficiency of the siRNA of interest; therefore, we fused the RNA recognition motif of U1-A with the C-terminus of Lamp2b, which interacts with the sequence "AUUGCAC" in the target RNA with a relatively high affinity. Then, a multi-siRNA was engineered to harbor the consensus "AUUGCAC" sequence. The preliminary data here indicate that the fusion protein helps sort multiple siRNAs containing the "AUUGCAC" sequence into exosomes during exosome biogenesis, especially when the RNA of interest is exogenously overexpressed. It is worth noting that due to the limitation of the present siRNA detection technology, the biological loading rate of multi-siRNA cannot be accurately detected in live cells and exosomes. Here, in the preparation of
functionalized exosomes, saturated amount of multi-siRNAs were transfected into cells to ensure that engineered exosomes were loaded with sufficient multi-siRNAs. Further experiments also confirmed that a large amount of multi-siRNAs could be effectively encapsulated into engineered exosomes and delivered to HCC cells, thus inducing down-regulation of GPX4 and DHODH. Our study established a novel strategy to efficiently load therapeutic multi-siRNA cargos into exosomes.

Currently, the poor solubility and potential off-target toxicity to normal cells and tissues preclude the systematic use of traditional ferroptosis inducers in vivo (32–34). Nanoscale exosomes are considered a good choice as a drug vehicle because exosomes could be engineered toward better targeting specificity via exosome surface protein modifications (35–39). For example, exosomes expressing the αβ integrin-specific iRGD peptide fused to LAMP-2b efficiently delivered doxorubicin to integrin-positive breast cancer cells in vitro and in vivo (40). Here, an HCC-specific targeting peptide, SP94, was fused to the extracellular domain of LAMP-2B at the N-terminus (21). Our data show that functionalized exosomes (ExoSP94-Lamp2b-RRM, multi-siRNA) can selectively deliver therapeutic cargos to human HCC cells with no obvious adverse effects. This is the first report of tumor-targeted exosome delivery of ferroptosis inducers, which might open a new avenue for the systematic use of ferroptosis inducers to treat cancer.

In summary, this study firstly identified that ferroptosis suppressor genes GPX4 and DHODH were enriched in sorafenib-resistant HCC and associated with compromised therapeutic efficiency of sorafenib. In addition, we described the use of multi-siRNA to enhance sorafenib-induced ferroptosis by simultaneously knocking down GPX4 and DHODH. More importantly, we designed HCC-targeted engineered exosomes (ExoSP94-Lamp2b-RRM) to deliver multi-siRNA, thus overcoming acquired resistance to sorafenib from the perspective of ferroptosis.
