May 18, 2017

Abstract

This paper analyzes the iteration-complexity of a generalized alternating direction method of multipliers (G-ADMM) for solving linearly constrained convex problems. This ADMM variant, which was first proposed by Bertsekas and Eckstein, introduces a relaxation parameter $\alpha \in (0, 2)$ into the second ADMM subproblem. Our approach is to show that the G-ADMM is an instance of a hybrid proximal extragradient framework with some special properties, and, as a by product, we obtain ergodic iteration-complexity for the G-ADMM with $\alpha \in (0, 2]$, improving and complementing related results in the literature. Additionally, we also present pointwise iteration-complexity for the G-ADMM.

2000 Mathematics Subject Classification: 47H05, 49M27, 90C25, 90C60, 65K10.

Key words: generalized alternating direction method of multipliers, hybrid extragradient method, convex program, pointwise iteration-complexity, ergodic iteration-complexity.

1 Introduction

This paper considers the following linearly constrained convex optimization problem

$$
\min \{ f(x) + g(y) : Ax + By = b, \ x \in \mathbb{R}^n, y \in \mathbb{R}^p \} \tag{1}
$$

where $f : \mathbb{R}^n \to \mathbb{R}$ and $g : \mathbb{R}^p \to \mathbb{R}$ are convex functions, $A \in \mathbb{R}^{m \times n}$, $B \in \mathbb{R}^{m \times p}$ and $b \in \mathbb{R}^m$. Problems with separable structure such as (1) arises in many applications areas, for instance, machine learning, compressive sensing and image processing. One popular method for solving (1), taking advantages of its special structure, is the alternating direction method of multipliers (ADMM) [13, 15]; for detailed reviews, see [2, 14]. Many variants of it have been considered in the literature; see, for example, [5, 8, 10, 12, 18, 19, 20, 21, 23, 27]. The ADMM variant studied here is the generalized ADMM [11] (G-ADMM) with proximal terms, described as follows: given $(x_{k-1}, y_{k-1}, \gamma_{k-1})$ compute $(x_k, y_k, \gamma_k)$ as

\[
\begin{align*}
    x_k &\in \arg\min_x \left\{ f(x) - \langle \gamma_{k-1}, Ax \rangle + \frac{\beta}{2} \| Ax + By_{k-1} - b \|^2 + \frac{1}{2} \| x - x_{k-1} \|^2_{H_1} \right\}, \\
y_k &\in \arg\min_y \left\{ g(y) - \langle \gamma_{k-1}, By \rangle + \frac{\beta}{2} \| \alpha (Ax_k + By_{k-1} - b) + B(y - y_{k-1}) \|^2 + \frac{1}{2} \| y - y_{k-1} \|^2_{H_2} \right\}, \\
\gamma_k &= \gamma_{k-1} - \beta \left[ \alpha (Ax_k + By_{k-1} - b) + B(y_k - y_{k-1}) \right] \tag{2}
\end{align*}
\]

where $\beta > 0$ is a fixed penalty parameter, $(H_1, H_2) \in \mathbb{R}^{n \times n} \times \mathbb{R}^{p \times p}$ are symmetric and positive semi-definite matrices, $\alpha \in (0, 2]$ is a relaxation factor and $\| \cdot \|^2_{H_i} := \langle H_i(\cdot), \cdot \rangle$, $i = 1, 2$. Different ADMM variants studied

(E-mails: vandomat32@hotmail.com, maxlng@ufg.br and jefferson@ufg.br). The work of these authors was supported in part by CNPq Grant 444134/2014-0, 309370/2014-0 and FAPEG/GO.
in the literature can be seen as particular instances of the G-ADMM by appropriately choosing the matrices \( H_i \) \((i = 1, 2)\) and the relaxation parameter \( \alpha \). By setting \((H_1, H_2) = (0, 0)\) and \( \alpha = 1 \), the G-ADMM reduces to the standard ADMM. The use of over-relaxation parameter \((\alpha > 1)\) in some applications can accelerate the standard ADMM; see, for instance, [9, 10]. By choosing \((H_1, H_2) = (T_\alpha I_n - \beta A^*A, T_\beta I_p - \beta B^*B)\) for some \( T_\alpha \geq \beta \|A\|^2 \), \( T_\beta \geq \beta \|B\|^2 \) (* stands for the adjoint operator), the G-ADMM subproblems may become much easier to solve, since the quadratic terms involving \( A^*A \) and \( B^*B \) vanish; see, for example, [8, 32, 33] for discussion. It is well-known that an optimal solution \((x^*, y^*)\) for problem (1) can be obtained by finding a solution \((x^*, y^*, \gamma^*)\) of the following Lagrangian system

\[
0 \in \partial f(x) - A^*\gamma, \quad 0 \in \partial g(y) - B^*\gamma, \quad Ax + By - b = 0,
\]

where \( \gamma^* \) is an associated Lagrange multiplier.

In this paper, we are interested in analyzing iteration-complexity of the G-ADMM to obtain an “approximate solution” of the Lagrangian system (3). Specifically, for a given tolerance \( \varepsilon > 0 \), we show that in at most \( O(1/\varepsilon) \) iterations of the G-ADMM, we obtain, in the ergodic sense, an “\( \varepsilon \)-approximate” solution \((\hat{x}, \hat{y}, \hat{\gamma})\) and a residual \( \hat{v} = (\hat{v}_1, \hat{v}_2, \hat{v}_3) \) of (3) satisfying

\[
\hat{v}_1 \in \partial_{x_1} f(\hat{x}) - A^*\hat{\gamma}, \quad \hat{v}_2 \in \partial_{x_2} g(\hat{y}) - B^*\hat{\gamma}, \quad \hat{v}_3 = A\hat{x} + B\hat{y} - b, \quad \|\hat{v}\|_{(H_1, H_2)} \leq \varepsilon, \quad \varepsilon_1 + \varepsilon_2 \leq \varepsilon,
\]

where the symbol \( \partial \) stands for \( \varepsilon \)-subdifferential, and \( \| \cdot \|_{(H_1, H_2)} \) is a norm (seminorm) depending on the matrices \( H_1 \) and \( H_2 \). Our approach is to show that the G-ADMM is an instance of a hybrid proximal extragradient (HPE) framework (see [24, 29]) with a very special property, namely, a key parameter sequence \( \{\rho_k\} \) associated to the sequence generated by the method is upper bounded by a multiple of \( d_0 \) (a parameter measuring, in some sense, the distance of the initial point to the solution set). This result is essential to obtain the ergodic iteration-complexity of the G-ADMM with relaxation parameter \( \alpha \in (0, 2) \). Additionally, we also present pointwise iteration-complexity for the G-ADMM with \( \alpha \in (0, 2) \).

Convergence rates of the G-ADMM and related variants have been studied by many authors in different contexts. In [12], the authors obtain pointwise and ergodic convergence rate bounds for the G-ADMM with \( \alpha \in (0, 2) \). Paper [20] studies linear convergence of the G-ADMM under additional assumptions. Some convergence rates are also proposed in order to choose the relaxation and penalty parameters. Linear convergence of the G-ADMM is also studied in [31] on a general setting. Paper [35] studies the G-ADMM as a particular case of a general scheme in a Hilbert space and measures, in an ergodic sense, a “partial” primal-dual gap associated to the augmented Lagrangian of problem (1). Paper [6] studies convergence rates of a generalized proximal point algorithm and obtains, as a by product, convergence rates of the particular instance of the G-ADMM in which \((H_1, H_2) = (0, 0)\). It is worth mentioning that the previous ergodic convergence results for the G-ADMM are not focused in solving (3) approximately in the sense of our paper. Iteration-complexity study of the standard ADMM and some variants in the setting of the HPE framework have been considered in [16, 18, 25]. Finally, convergence rates of ADMM variants using a different approach have been studied in [7, 8, 18, 20, 21, 22, 23, 26, 27], to name just a few.

**Organization of the paper.** Section 2 is divided into two subsections, Subsection 2.1 presents our notation and basic results. Subsection 2.2 is devoted to the study of a modified HPE framework and present its main iteration-complexity results whose proofs are given in Section A. Section 3 is divided into three subsections. Subsection 3.1 formally describes the generalized ADMM and Subsection 3.2 contains some auxiliary results. The pointwise and ergodic iteration-complexity results for the G-ADMM are given in Subsection 3.3.

## 2 Preliminary results

This section is divided into two subsections: The first one presents our notation and basic results, and the second one describes a modified HPE framework and present its iteration-complexity bounds.
2.1 Notation and basic definitions

This subsection presents some definitions, notation and basic results used in this paper.

Let $\mathcal{V}$ be a finite-dimensional real vector space with inner product and associated norm denoted by $\langle \cdot, \cdot \rangle$ and $\| \cdot \|$, respectively. For a given self-adjoint positive semidefinite linear operator $Q : \mathcal{V} \to \mathcal{V}$, the seminorm induced by $Q$ on $\mathcal{V}$ is defined by $\| \cdot \|_Q = \langle \cdot, \cdot \rangle^{1/2}$. Since $\langle \cdot, \cdot \rangle$ is symmetric and bilinear, for all $v, \tilde{v} \in \mathcal{V}$, we have

$$2 \langle Qv, \tilde{v} \rangle \leq \|v\|^2_Q + \|\tilde{v}\|^2_Q. \quad (4)$$

Given a set-valued operator $T : \mathcal{V} \rightrightarrows \mathcal{V}$, its domain and graph are defined, respectively, as

$$\text{Dom } T := \{v \in \mathcal{V} : T(v) \neq \emptyset\} \quad \text{and} \quad \text{Gr}(T) = \{(v, \tilde{v}) \in \mathcal{V} \times \mathcal{V} \mid \tilde{v} \in T(v)\}.$$ 

The operator $T$ is said to be monotone if

$$\langle u - v, \tilde{u} - \tilde{v} \rangle \geq 0 \quad \forall (u, \tilde{u}), (v, \tilde{v}) \in \text{Gr}(T).$$

Moreover, $T$ is maximal monotone if it is monotone and there is no other monotone operator $S$ such that $\text{Gr}(T) \subset \text{Gr}(S)$. Given a scalar $\varepsilon \geq 0$, the $\varepsilon$-enlargement $T^{[\varepsilon]} : \mathcal{V} \rightrightarrows \mathcal{V}$ of a monotone operator $T : \mathcal{V} \rightrightarrows \mathcal{V}$ is defined as

$$T^{[\varepsilon]}(v) := \{\tilde{v} \in \mathcal{V} : \langle \tilde{v} - \tilde{u}, v - u \rangle \geq -\varepsilon, \forall (u, \tilde{u}) \in \text{Gr}(T)\} \quad \forall v \in \mathcal{V}. \quad (5)$$

The $\varepsilon$-subdifferential of a proper closed convex function $f : \mathcal{V} \to [-\infty, \infty]$ is defined by

$$\partial_\varepsilon f(v) := \{u \in \mathcal{V} : f(v) \geq f(v) + \langle u, \tilde{v} - v \rangle - \varepsilon, \forall \tilde{v} \in \mathcal{V}\} \quad \forall v \in \mathcal{V}.$$ 

When $\varepsilon = 0$, then $\partial_0 f(v)$ is denoted by $\partial f(v)$ and is called the subdifferential of $f$ at $v$. It is well known that the subdifferential operator of a proper closed convex function is maximal monotone [28].

The next theorem is a consequence of the transportation formula in [4, Theorem 2.3] combined with [3, Proposition 2(i)]

**Theorem 2.1.** Suppose $T : \mathcal{V} \rightrightarrows \mathcal{V}$ is maximal monotone and let $\tilde{v}_i, v_i \in \mathcal{V}$, for $i = 1, \cdots, k$, be such that $v_i \in T(\tilde{v}_i)$ and define

$$\tilde{v}_k^a = \frac{1}{k} \sum_{i=1}^k \tilde{v}_i, \quad v_k^a = \frac{1}{k} \sum_{i=1}^k v_i, \quad \varepsilon_k^a = \frac{1}{k} \sum_{i=1}^k (v_i, \tilde{v}_i - \tilde{v}_k^a).$$

Then, the following hold:

(a) $\varepsilon_k^a \geq 0$ and $v_k^a \in T^{[\varepsilon_k^a]}(\tilde{v}_k^a)$;

(b) if, in addition, $T = \partial f$ for some proper closed and convex function $f$, then $v_k^a \in \partial f(\tilde{v}_k^a)$. 

2.2 A HPE-type framework

This subsection describes the modified HPE framework and its corresponding pointwise and ergodic iteration-complexity bounds.

Let $\mathcal{Z}$ be a finite-dimensional real vector space with inner product and induced norm denoted by $\langle \cdot, \cdot \rangle$ and $\| \cdot \| = \sqrt{\langle \cdot, \cdot \rangle}$, respectively. Our problem of interest in this section is the monotone inclusion problem (MIP)

$$0 \in T(z) \quad (6)$$

where $T : \mathcal{Z} \rightrightarrows \mathcal{Z}$ is a maximal monotone operator. We assume that the solution set of (6), denoted by $T^{-1}(0)$, is nonempty.

We now state the modified HPE framework for solving (6).
A modified HPE framework for solving (3).

(0) Let \( z_0 \in \mathcal{Z}, \eta_0 \in \mathbb{R}_+ \), \( \sigma \in [0,1] \) and a self-adjoint positive semidefinite linear operator \( M : \mathcal{Z} \to \mathcal{Z} \) be given, and set \( k = 1 \):

(1) obtain \((z_k, \tilde{z}_k, \eta_k) \in \mathcal{Z} \times \mathcal{Z} \times \mathbb{R}_+ \) such that

\[
M(z_{k-1} - z_k) \in T(\tilde{z}_k),
\]

\[
\|\tilde{z}_k - z_k\|_M^2 + \eta_k \leq \sigma\|\tilde{z}_k - z_{k-1}\|_M^2 + \eta_{k-1};
\]

(2) set \( k \leftarrow k + 1 \) and go to step 1.

end

Some remarks about the modified HPE framework are in order. First, it is an instance of the non-Euclidean HPE framework of [17] with \( \lambda_k = 1, \varepsilon_k = 0 \) and \( (dw)_{z}(z') = (1/2)\|z - z'\|^2 \) for every \( z, z' \in \mathcal{Z} \). Second, the way to obtain \((z_k, \tilde{z}_k, \eta_k) \) will depend on the particular instance of the framework and properties of the operator \( T \). In section 3.2, we will show that a generalized ADMM can be seen as an instance of the HPE framework, specifying, in particular, how this triple \((z_k, \tilde{z}_k, \eta_k) \) can be obtained. Third, if \( M \) is positive definite and \( \sigma = \eta_0 = 0 \), then \( \|z_0\|_M \leq \|\tilde{z}_0\|_M \) implies that \( \eta_k = 0 \) and \( z_k = \tilde{z}_k \) for every \( k \), and hence that \( M(z_{k-1} - z_k) \in T(\tilde{z}_k) \) in view of (7). Therefore, the HPE error conditions (7)-(8) can be viewed as a relaxation of an iteration of the exact proximal point method.

In the following, we present pointwise and ergodic iteration-complexity results for the modified HPE framework. Let \( d_0 \) be the distance of \( z_0 \) to the solution set of \( T^{-1}(0) \), i.e.,

\[
d_0 = \inf\{\|z^* - z_0\|^2 : z^* \in T^{-1}(0)\}.
\]

For convenience of the reader and completeness, the proof of the next two results are presented in Appendix A.

**Theorem 2.2. (Pointwise convergence of the HPE)** Consider the sequence \( \{(z_k, \tilde{z}_k, \eta_k)\} \) generated by the modified HPE framework with \( \sigma < 1 \). Then, for every \( k \geq 1 \), there hold \( 0 \in M(z_k - z_{k-1}) + T(\tilde{z}_k) \) and there exists \( i \leq k \) such that

\[
\|z_i - z_{i-1}\|_M \leq \frac{1}{\sqrt{k}}\sqrt{\frac{2(1 + \sigma)d_0 + 4\eta_0}{1 - \sigma}},
\]

where \( d_0 \) is as defined in (9).

Next, we present the ergodic convergence of the modified HPE framework. Before, let us consider the following ergodic sequences

\[
\tilde{z}_k^a := \frac{1}{k} \sum_{i=1}^{k} \tilde{z}_i, \quad r_k^a := \frac{1}{k} \sum_{i=1}^{k} (z_i - z_{i-1}), \quad \varepsilon_k^a := \frac{1}{k} \sum_{i=1}^{k} (M(z_i - z_{i-1}), \tilde{z}_k^a - \tilde{z}_i), \quad \forall k \geq 1.
\]

**Theorem 2.3. (Ergodic convergence of the HPE)** Consider the ergodic sequence \( \{(\tilde{z}_k^a, r_k^a, \varepsilon_k^a)\} \) as in (10). For every \( k \geq 1 \), there hold \( \varepsilon_k^a \geq 0, 0 \in M r_k^a + T[\tilde{z}_k^a] \) and

\[
\|r_k^a\|_M \leq \frac{2\sqrt{d_0 + \eta_0}}{k}, \quad \varepsilon_k^a \leq \frac{3[3d_0 + \eta_0 + \sigma\rho_k]}{2k},
\]

where

\[
\rho_k := \max_{i=1,\ldots,k} \|\tilde{z}_i - z_{i-1}\|_M^2;
\]

and \( d_0 \) is as defined in (9). Moreover, the sequence \( \{\rho_k\} \) is bounded under either one of the following situations:

(a) \( \sigma < 1 \), in which case

\[
\rho_k \leq \frac{d_0 + \eta_0}{1 - \sigma};
\]

(b) \( \sigma = 1 \), in which case

\[
\rho_k \leq \frac{d_0 + \eta_0}{1 - \sigma};
\]

(c) \( \sigma = \eta_0 = 0 \), in which case

\[
\rho_k \leq \frac{d_0 + \eta_0}{1 - \sigma};
\]

(d) \( \sigma > 1 \), in which case

\[
\rho_k \leq \frac{d_0 + \eta_0}{1 - \sigma}.
\]
(b) $\text{Dom} T$ is bounded, in which case

$$\rho_k \leq 2|d_0 + \eta_0 + D|,$$

where $D := \sup\{\|y' - y\|_M^2 : y, y' \in \text{Dom} T\}$.

If $\sigma < 1$ or $\text{Dom} T$ is bounded, it follows from Theorem 2.3 that $\{\rho_k\}$ is bounded and hence $\max\{\|r_k^o\|_M, \varepsilon_k^o\} = O(1/k)$. However, it may happen that the sequence $\{\rho_k\}$ is bounded even when $\sigma = 1$. Indeed, in the next section, we will present a generalized ADMM which is an instance of the modified HPE framework satisfying this case (see Lemma (3.5)).

### 3 The generalized ADMM and its convergence rates

The main goal of this section is to describe the generalized ADMM for solving (1) and present pointwise and ergodic iteration-complexity results for it. Our iteration-complexity bounds are obtained by showing that this ADMM variant is a special case of the modified HPE framework of Section 2.2.

Throughout this section, we assume that:

- **A1** the problem (1) has an optimal solution $(x^*, y^*)$ and an associated Lagrange multiplier $\gamma^*$, or equivalently, the inclusion
  
  $$0 \in T(x, y, \gamma) := \begin{bmatrix} \partial f(x) - A^*\gamma \\ \partial g(y) - B^*\gamma \\ Ax + By - b \end{bmatrix}$$

  has a solution $(x^*, y^*, \gamma^*)$.

#### 3.1 The generalized ADMM

In this subsection, we recall the generalized ADMM first proposed by Eckstein and Bertsekas (see [9, 11, 12]) for solving (1).

| Generalized ADMM |
|-------------------|
| (0) Let an initial point $(x_0, y_0, \gamma_0) \in \mathbb{R}^n \times \mathbb{R}^p \times \mathbb{R}^m$, a penalty parameter $\beta > 0$, a relaxation factor $\alpha \in (0, 2]$, and symmetric positive semidefinite matrices $H_1 \in \mathbb{R}^{n \times n}$ and $H_2 \in \mathbb{R}^{p \times p}$ be given, and set $k = 1$; |
| (1) compute an optimal solution $x_k \in \mathbb{R}^n$ of the subproblem |
| $\min_{x \in \mathbb{R}^n} \left\{ f(x) - \langle \gamma_{k-1}, A x \rangle + \frac{\beta}{2} \|A x + B y_{k-1} - b\|^2 + \frac{1}{2} \|x - x_{k-1}\|^2_{H_1} \right\}$ |
| and compute an optimal solution $y_k \in \mathbb{R}^p$ of the subproblem |
| $\min_{y \in \mathbb{R}^p} \left\{ g(y) - \langle \gamma_{k-1}, B y \rangle + \frac{\beta}{2} \|A x_k + B y_{k-1} - b\|^2 + \frac{1}{2} \|y - y_{k-1}\|^2_{H_2} \right\}$; |
| (2) set |
| $\gamma_k = \gamma_{k-1} - \beta[\alpha(A x_k + B y_{k-1} - b) + B(y - y_{k-1})]$ |
| and $k \leftarrow k + 1$, and go to step (1). |

end

The generalized ADMM has different features depending on the choices of the operators $H_1$, $H_2$, and the relaxation factor $\alpha$. For instance, by taking $\alpha = 1$ and $(H_1, H_2) = (0, 0)$, it reduces to the standard ADMM, and $\alpha = 1$ and $(H_1, H_2) = (\tau_1 I_n - \beta A^* A, \tau_2 I_p - \beta B^* B)$ with $\tau_1 > \beta\|A^* A\|$ and $\tau_2 > \beta\|B^* B\|$, it reduces to
the linearized ADMM. The latter method basically consists of canceling the quadratic terms \((\beta/2)\|Ax\|^2\) and \((\beta/2)\|By\|^2\) in (19) and (15), respectively. More specifically, the subproblems (14) and (15) become
\[
\begin{aligned}
\min_{x \in \mathbb{R}^n} & \left\{ f(x) - \langle \gamma_{k-1} - \beta(Ax_{k-1} + By_{k-1} - b), Ax \rangle + \frac{T_1}{2} \|x - x_{k-1}\|^2 \right\}, \\
\min_{y \in \mathbb{R}^p} & \left\{ g(y) - \langle \gamma_{k-1} - \alpha \beta(Ax_k + By_{k-1} - b), By \rangle + \frac{T_2}{2} \|y - y_{k-1}\|^2 \right\}.
\end{aligned}
\]

In many applications, the above subproblems are much easier to solve or even have closed-form solutions (see \([21, 32, 33]\) for more details). We also mention that depending on the structure of problem (1), other choices of \(H_1\) and \(H_2\) may be recommended; see, for instance, \([8]\) (although the latter reference considers \(\alpha = 1\), it is clear that the same discussion regarding the choices of \(H_1\) and \(H_2\) holds for arbitrary \(\alpha \in (0, 2)\)). The generalized ADMM with over-relaxation parameter \((\alpha > 1)\) may present computational advantages over the standard ADMM (see, for example, \([4]\)).

### 3.2 The generalized ADMM as an instance of the modified HPE framework

Our aim in this subsection is to show that the generalized ADMM is an instance of the modified HPE framework for solving the inclusion problem (13) and, as a by-product, pointwise and ergodic iteration-complexity bounds results for the generalized ADMM will be presented in Subsection 3.3.

Let us first introduce the elements required by the setting of Subsection 2.2. Consider the vector space \(Z := \mathbb{R}^n \times \mathbb{R}^p \times \mathbb{R}^m\), the linear operator
\[
M := \begin{bmatrix}
H_1 & 0 & 0 \\
0 & (H_2 + \frac{\beta}{\alpha} B^* B) & \frac{0}{\alpha} B^* \\
0 & \frac{(1-\alpha)}{\alpha} B & \frac{1}{\alpha \beta} I_m
\end{bmatrix},
\]
and the quantity
\[
d_0 := \inf_{(x,y,\gamma) \in T^{-1}(0)} \left\{ \| (x - x_0, y - y_0, \gamma - \gamma_0) \|_M^2 \right\}.
\]
(18)

It is easy to verify that \(M\) is a symmetric positive semidefinite matrix for every \(\beta > 0\) and \(\alpha \in (0, 2]\). Let \((x_k, y_k, \gamma_k)\) be the sequence generated by the generalized ADMM. In order to simplify some relations in the results below, define the sequence \((\Delta x_k, \Delta y_k, \Delta \gamma_k, \tilde{\gamma}_k)\) as
\[
\Delta x_k = x_k - x_{k-1}, \quad \Delta y_k = y_k - y_{k-1}, \quad \Delta \gamma_k = \gamma_k - \gamma_{k-1}, \quad \tilde{\gamma}_k = \gamma_{k-1} - \beta(Ax_k + By_{k-1} - b)
\]
(19)
for every \(k \geq 1\).

We next present two technical results on the generalized ADMM.

**Lemma 3.1.** Let \((x_k, y_k, \gamma_k)\) be generated by the generalized ADMM and consider \((\Delta x_k, \Delta y_k, \Delta \gamma_k, \tilde{\gamma}_k)\) as in (19). Then, for every \(k \geq 1\),
\[
\tilde{\gamma}_k - \gamma_{k-1} = \frac{1}{\alpha} [\Delta \gamma_k + \beta B \Delta y_k],
\]
(20)
\[
0 \in H_1 \Delta x_k + [\partial f(x_k) - A^* \tilde{\gamma}_k],
\]
(21)
\[
0 \in (H_2 + \frac{\beta}{\alpha} B^* B) \Delta y_k + \frac{(1-\alpha)}{\alpha} B^* \Delta \gamma_k + [\partial g(y_k) - B^* \tilde{\gamma}_k],
\]
(22)
\[
0 = \frac{(1-\alpha)}{\alpha} B \Delta y_k + \frac{1}{\alpha \beta} \Delta \gamma_k + [Ax_k + By_k - b].
\]
(23)
As a consequence, \(z_k := (x_k, y_k, \gamma_k)\) and \(\tilde{z}_k := (x_k, y_k, \tilde{\gamma}_k)\) satisfy the inclusion (7) with \(T\) and \(M\) as in (13) and (17), respectively.
Proof. It follows from definitions of \(\gamma_k\) and \(\check{\gamma}_k\) in (16) and (19), respectively, that
\[
\frac{1}{\alpha} (\gamma_k - \gamma_{k-1}) + \frac{\beta}{\alpha} B(y_k - y_{k-1}) = -\beta (Ax_k + By_{k-1} - b) = \check{\gamma}_k - \gamma_{k-1},
\]
which, combined with definitions of \(\Delta y_k\) and \(\Delta \gamma_k\) in (19), proves (20). From the optimality condition for (14), we have
\[
0 \in \partial f(x_k) - A^*(\gamma_{k-1} - \beta (Ax_k + By_{k-1} - b)) + H_1(x_k - x_{k-1}),
\]
which, combined with definitions of \(\check{\gamma}_k\) and \(\Delta x_k\) in (19), yields (21). Similarly, from the optimality condition for (14) and definitions of \(\gamma_k\) and \(\Delta y_k\) in (16) and (21), respectively, we obtain
\[
0 \in \partial g(y_k) - B^* [\gamma_{k-1} - \beta \alpha (Ax_k + By_{k-1} - b) + \beta B(y_k - y_{k-1})] + H_2(y_k - y_{k-1}) = \partial g(y_k) - B^* \gamma_k + H_2 \Delta y_k.
\]
On the other hand, note that (20) implies that
\[
\gamma_k = \check{\gamma}_k + (\gamma_k - \gamma_{k-1}) - (\check{\gamma}_k - \gamma_{k-1}) = \check{\gamma}_k - \frac{(1 - \alpha)}{\alpha} \Delta \gamma_k - \frac{\beta}{\alpha} B \Delta y_k,
\]
which in turn, combined with (24), gives (22). The relation (23) follows immediately from (16).

Now, the last statement of the lemma follows directly by (21)–(23) and definitions of \(T\) and \(M\) given in (18) and (17), respectively.

**Lemma 3.2.** The sequences \(\{\Delta y_k\}\) and \(\{\Delta \gamma_k\}\) defined in (19) satisfy
\[
2(B \Delta y_1, \Delta \gamma_1) \geq \|\Delta y_1\|^2_{H_2} - 4d_0, \quad 2(B \Delta y_k, \Delta \gamma_k) \geq \|\Delta y_{k-1}\|^2_{H_2} - \|\Delta y_k\|^2_{H_2} \forall k \geq 2,
\]
where \(d_0\) is as in (15).

*Proof.* Let a point \(z^* := (x^*, y^*, \gamma^*)\) be such that \(0 \in T(x^*, y^*, \gamma^*)\) (see assumption A1) and consider \(z_i := (x_i, y_i, \gamma_i), i = 0, 1, \) First, note that
\[
0 \leq \frac{\beta}{\alpha} \|B \Delta y_1\|^2 + \frac{2}{\alpha} (B \Delta y_1, \Delta \gamma_1) + \frac{1}{\alpha \beta} \|\Delta \gamma_1\|^2,
\]
where \(\Delta y_1\) and \(\Delta \gamma_1\) are as in (19). Hence, by adding \(\|\Delta y_1\|^2_{H_2} - 2(B \Delta y_1, \Delta \gamma_1)\) to both sides of the above inequality, we obtain
\[
\|\Delta y_1\|^2_{H_2} - 2(B \Delta y_1, \Delta \gamma_1) \leq \|\Delta y_1\|^2_{H_2} + \frac{\beta}{\alpha} \|B \Delta y_1\|^2 + 2 \frac{(1 - \alpha)}{\alpha} (B \Delta y_1, \Delta \gamma_1) + \frac{1}{\alpha \beta} \|\Delta \gamma_1\|^2
\]
\[
\leq \|z_1 - z_0\|^2_M \leq 2 \left( \|z^* - z_1\|^2_M + \|z^* - z_0\|^2_M \right),
\]
where \(M\) is as in (17) and the last inequality is a consequence of (14) with \(Q = M\). On the other hand, taking \(\tilde{z}_1 = (x_1, y_1, \check{\gamma}_1)\), Lemma 3.1 implies that \((z_0, z_1, \tilde{z}_1)\) satisfies (7) with \(T\) and \(M\) as in (13) and (17), respectively; namely, \(M(z_0 - z_1) \in T(\tilde{z}_1)\). Hence, since \(0 \in T(z^*)\) and \(T\) is monotone, we obtain \((M(z_0 - z_1), \tilde{z}_1 - z^*) \geq 0\). Thus, it follows that
\[
\|z^* - z_1\|^2_M - \|z^* - z_0\|^2_M = \|(z^* - \tilde{z}_1) + (\tilde{z}_1 - z_1)\|^2_M - \|(z^* - \tilde{z}_1) + (\tilde{z}_1 - z_0)\|^2_M
\]
\[
= \|\tilde{z}_1 - z_1\|^2_M + 2(M(z_0 - z_1), z^* - \tilde{z}_1) - \|\tilde{z}_1 - z_0\|^2_M
\]
\[
\leq \|\tilde{z}_1 - z_1\|^2_M - \|\tilde{z}_1 - z_0\|^2_M.
\]
Combining (19) and (20), we have \(\check{\gamma}_1 - \gamma_1 = [(1 - \alpha) \Delta \gamma_1 + \beta B \Delta y_1]/\alpha\). Hence, using the definitions of \(M, z_1\) and \(\tilde{z}_1\), we obtain
\[
\|\tilde{z}_1 - z_1\|^2_M = \frac{1}{\alpha \beta} \|\check{\gamma}_1 - \gamma_1\|^2 = \frac{\beta}{\alpha^2} \|B \Delta y_1\|^2 + 2 \frac{(1 - \alpha)}{\alpha^2} (B \Delta y_1, \Delta \gamma_1) + \frac{(1 - \alpha)^2}{\alpha^2 \beta} \|\Delta \gamma_1\|^2.
\]
Thus, it follows from (27) that
\[ \frac{\beta}{\alpha} \|B(y_1 - y_0)\|^2 + \frac{2(1 - \alpha)}{\alpha} (B(y_1 - y_0), \gamma_1 - \gamma_0) + \frac{1}{\alpha \beta} \|\gamma_1 - \gamma_0\|^2 \]
\[ = \left( \frac{\beta}{\alpha} + \frac{2(1 - \alpha)\beta}{\alpha^2} + \frac{\beta}{\alpha^3} \right) \|B\Delta y_1\|^2 + 2 \left( \frac{(1 - \alpha)}{\alpha^2} + \frac{1}{\alpha^3} \right) (B\Delta y_1, \Delta \gamma_1) + \frac{1}{\alpha^3 \beta} \|\Delta \gamma_1\|^2, \]
where the last equality is due to (11) and (20). Hence, it is easy to see that
\[ \|\tilde{z}_1 - z_1\|^2_M - \|\tilde{z}_1 - z_0\|^2_M \leq \frac{(\alpha - 2)}{\alpha^2} \left( \sqrt{\beta} B\Delta y_1 + \frac{1}{\sqrt{\beta}} \Delta \gamma_1 \right)^2 \leq 0. \]
Thus, it follows from (28) that
\[ \|z^* - z_1\|^2_M \leq \|z^* - z_0\|^2_M, \]
which, combined with (20), yields
\[ \|\Delta y_1\|^2_{H_2} - 2\langle B\Delta y_1, \Delta \gamma_1 \rangle \leq 4\|z^* - z_0\|^2_M. \]
Therefore, the first inequality in (25) follows from definition of $d_0$ (see (18)) and the fact that $z^* \in T^{-1}(0)$ is arbitrary.

Let us now prove the second inequality in (25). First, from the optimality condition of (15) and (16), we obtain
\[ B^*\gamma_j - H_2(y_j - y_{j-1}) \in \partial g(y_j) \quad \forall j \geq 1.\]
For every $k \geq 2$, using the previous inclusion for $j = k - 1$ and $j = k$, it follows from the monotonicity of the subdifferential of $g$ that
\[ \langle B^* (\gamma_k - \gamma_{k-1}) - H_2(y_k - y_{k-1}) + H_2(y_{k-1} - y_{k-2}), y_k - y_{k-1} \rangle \geq 0, \]
which, combined with (19), yields
\[ \langle B\Delta y_k, \Delta \gamma_k \rangle \geq \|\Delta y_k\|^2_{H_2} - \langle H_2\Delta y_{k-1}, \Delta y_k \rangle \quad \forall k \geq 2. \]
To conclude the proof, use the relation (21) with $Q = H_2$. \hfill \square

The following theorem shows that the generalized ADMM is an instance of the modified HPE framework. Let us consider the following quantity:
\[ \sigma_\alpha = \frac{1}{1 + \alpha(2 - \alpha)} \quad \text{(28)} \]
Note that $\sigma_2 = 1$, and for any $\alpha \in (0, 2)$ we have $\sigma_\alpha \in (0, 1)$.

**Theorem 3.3.** Let $\{(x_k, y_k, \gamma_k)\}$ be generated by the generalized ADMM and consider $\{ (\Delta y_k, \gamma_k) \}$ and $\sigma_\alpha$ as in (19) and (28), respectively. Define
\[ z_{k-1} = (x_{k-1}, y_{k-1}, \gamma_{k-1}) \quad \tilde{z}_k = (x_k, y_k, \gamma_k), \quad \forall k \geq 1, \quad \text{(29)} \]
and
\[ \eta_0 = \frac{4(2 - \alpha)\sigma_\alpha}{\alpha} d_0, \quad \eta_k = \frac{(2 - \alpha)\sigma_\alpha}{\alpha} \|\Delta y_k\|^2_{H_2}, \quad \forall k \geq 1, \quad \text{(30)} \]
where $d_0$ is as in (18). Then, the sequence $\{(z_k, \tilde{z}_k, \eta_k)\}$ is an instance of the modified HPE framework applied for solving (13), where $\sigma := \sigma_\alpha$ and $M$ is as in (17).
every generalized ADMM with \( \alpha \).

Theorem 3.4. (Pointwise convergence of the generalized ADMM) Let us now show that (8) holds. Using (19), (20) and (29), we obtain

\[
\frac{1}{\alpha^3 \beta} \| \tilde{y}_k - y_k \|^2 = \frac{1}{\alpha \beta} \| \gamma_k - \gamma_{k-1} \|^2 = \frac{1}{\alpha \beta} \left( (1 - \alpha) \Delta \gamma_k + \beta \Delta y_k \right)
\]

Also, (19) and (20) imply that

\[
\| \tilde{z}_k - z_{k-1} \|^2 = \| \Delta x_k \|^2 + \| \Delta y_k \|^2 + \frac{\beta}{\alpha} \| \Delta y_k \|^2 + 2 \frac{(1 - \alpha)}{\alpha} \langle B \Delta y_k, \Delta \gamma_k \rangle + \frac{1}{\alpha^2} \| y_k - y_{k-1} \|^2.
\]

It follows from (20) that

\[
\frac{1}{\alpha \beta} \| \tilde{y}_k - y_k \|^2 = \frac{1}{\alpha \beta} \left( \| \Delta \gamma_k \|^2 + 2 \beta \langle B \Delta y_k, \Delta \gamma_k \rangle + \beta^2 \| B \Delta y_k \|^2 \right),
\]

which, combined with (32), yields

\[
\| \tilde{z}_k - z_{k-1} \|^2 = \| \Delta x_k \|^2 + \| \Delta y_k \|^2 + \left( \frac{\beta}{\alpha} + 2 \frac{(1 - \alpha) \beta}{\alpha^2} + \beta \right) \| B \Delta y_k \|^2
\]

\[
+ 2 \left( \frac{(1 - \alpha)}{\alpha^2} + \frac{1}{\alpha} \right) \| B \Delta y_k, \Delta \gamma_k \| + \frac{1}{\alpha^3 \beta} \| B \Delta y_k \|^2.
\]

Therefore, combining (31) and (33), it is easy to verify that

\[
\sigma \| \tilde{z}_k - z_{k-1} \|^2 - \| \tilde{z}_k - z_k \|^2 = \sigma \| \Delta x_k \|^2 + \sigma \| \Delta y_k \|^2 + \frac{2 (1 - \alpha) \sigma}{\alpha} \| B \Delta y_k, \Delta \gamma_k \| + \frac{(1 - \alpha) \sigma}{\alpha^3} \| B \Delta y_k \|^2
\]

\[
\geq 2 \frac{(1 - \alpha) \sigma}{\alpha} \| B \Delta y_k, \Delta \gamma_k \| \geq \eta_k - \eta_{k-1} \quad \forall k \geq 1,
\]

where \( \sigma \) is as in (28), and the last inequality is due to (25) and (30). Therefore, (5) holds, and then we conclude that the sequence \( \{ (z_k, \tilde{z}_k, \eta_k) \} \) is an instance of the modified HPE framework.

3.3 Iteration-complexity bounds for the generalized ADMM

In this subsection, we study pointwise and ergodic iteration-complexity bounds for the generalized ADMM. We start by presenting a pointwise bound under the assumption that the relaxation parameter \( \alpha \) belongs to \( (0, 2) \). Then, we consider an auxiliary result which is used to show that the sequence \( \{ \rho_k \} \), as defined in Theorem 2.3 with \( \{ z_k \} \) and \( \{ \tilde{z}_k \} \) as in (29), is bounded even in the extreme case in which \( \alpha = 2 \). This latter result is then used to present the ergodic bounds of the generalized ADMM for any \( \alpha \in (0, 2) \).

Theorem 3.4. (Pointwise convergence of the generalized ADMM) Let \( \{ (x_k, y_k, \gamma_k) \} \) be generated by the generalized ADMM with \( \alpha \in (0, 2) \) and consider the sequence \( \{ (\Delta x_k, \Delta y_k, \Delta \gamma_k) \} \) as in (19). Then, for every \( k \geq 1 \),

\[
0 \in M \begin{pmatrix} \Delta x_k \\ \Delta y_k \\ \Delta \gamma_k \end{pmatrix} + \begin{pmatrix} \partial f(x_k) - A^* \tilde{\gamma}_k \\ \partial g(y_k) - B^* \tilde{\gamma}_k \\ A x_k + B y_k - b \end{pmatrix}
\]
and there exists $i \leq k$ such that

$$
\|(\Delta x_i, \Delta y_i, \Delta \gamma_i)\| \leq \frac{1}{\sqrt{k}} \sqrt{\frac{2|\alpha(1 + \sigma_\alpha) + 8(2 - \alpha)\sigma_\alpha|d_0}{\alpha(1 - \sigma_\alpha)}},
$$

where $M$, $d_0$, and $\sigma_\alpha$ are as (14), (18) and (28), respectively.

**Proof.** Since $\sigma_\alpha \in (0, 1)$ for any $\alpha \in (0, 2)$ (see (28)), we obtain by combining Theorems 2.2 and 3.3 that (34) holds and there exists $i \leq k$ such that

$$
\|(\Delta x_i, \Delta y_i, \Delta \gamma_i)\| \leq \frac{1}{\sqrt{k}} \sqrt{\frac{2(1 + \sigma_\alpha)d_0 + 4\eta_0}{1 - \sigma_\alpha}}.
$$

Hence, to conclude the proof use the definition of $\eta_0$ given in (30). \qed

For a given tolerance $\varepsilon > 0$, Theorem 3.4 implies that in at most $O(1/\varepsilon^2)$ iterations, the G-ADMM obtains an “$\varepsilon$-approximate” solution $(x, y, \gamma)$ and a residual $v$ of (3) satisfying

$$
Mv \in T(x, y, \gamma), \quad \|v\| \leq \varepsilon,
$$

where $T$ and $M$ are as (13) and (17), respectively.

Next we consider an auxiliary result which will be used to obtain ergodic iteration-complexity bounds for the generalized ADMM.

**Lemma 3.5.** Let $\{(x_k, y_k, \gamma_k)\}$ be generated by the generalized ADMM and consider $\{((\Delta x_k, \Delta y_k, \Delta \gamma_k), \tilde{v}_k)\}$ as in (19). Then, the sequence $\{\rho_k\}$ given in (11) with $M$ and $\{(z_k, \tilde{z}_k)\}$ as in (17) and (29), respectively, satisfies

$$
\rho_k \leq \frac{4(1 + 2\alpha)|\alpha + 4(2 - \alpha)\sigma_\alpha|d_0}{\alpha^3} \quad \forall k \geq 1,
$$

where $d_0$ is as in (13).

**Proof.** The same argument used to prove (32) and (33) yields, for every $k \geq 1$,

$$
\|\tilde{z}_k - z_{k-1}\|_M^2 = \|\Delta x_k\|_{H_1}^2 + \|\Delta y_k\|_{H_2}^2 + \xi_k,
$$

where

$$
\xi_k := \frac{\beta}{\alpha^3} \|B\Delta y_k\|^2 + \frac{2(1 - \alpha)}{\alpha^3} B\Delta y_k, \Delta \gamma_k + \frac{1}{\alpha^3 \beta} \|\Delta \gamma_k\|^2 + \frac{2 - \alpha}{\alpha^3} \left[\frac{\beta}{\alpha} \|B\Delta y_k\|^2 + \frac{2}{\alpha} (B\Delta y_k, \Delta \gamma_k)\right].
$$

Using the definitions of $M$ and $z_k$ given in (17) and (29), respectively, it follow that

$$
\xi_k \leq \frac{1}{\alpha^2} \|z_k - z_{k-1}\|_M^2 + \frac{2 - \alpha}{\alpha^2} \left[\frac{\beta}{\alpha} \|B\Delta y_k\|^2 + \frac{2}{\alpha} (B\Delta y_k, \Delta \gamma_k)\right]
$$

$$
= \frac{1}{\alpha^2} \|z_k - z_{k-1}\|_M^2 + \frac{2 - \alpha}{\alpha^2} \left[\frac{\beta}{\alpha} \|B\Delta y_k\|^2 + \frac{2(1 - \alpha)}{\alpha} (B\Delta y_k, \Delta \gamma_k)\right] + \frac{2(2 - \alpha)}{\alpha} (B\Delta y_k, \Delta \gamma_k)
$$

$$
\leq \frac{1}{\alpha^2} \|z_k - z_{k-1}\|_M^2 + \frac{2 - \alpha}{\alpha^2} \|z_k - z_{k-1}\|_M^2 + \frac{2(1 - \alpha)}{\alpha} (B\Delta y_k, \Delta \gamma_k) + \frac{2}{\alpha} (B\Delta y_k, \Delta \gamma_k)
$$

$$
\leq \frac{1 + 2\alpha - \alpha^2}{\alpha^2} \|z_k - z_{k-1}\|_M^2 + \frac{2(1 - \alpha)}{\alpha} (B\Delta y_k, \Delta \gamma_k) + \frac{\beta}{\alpha} \|B\Delta y_k\|^2 + \frac{1}{\alpha \beta} \|\Delta \gamma_k\|^2,
$$

where in the last two inequalities we used the fact that $\alpha \in (0, 2]$ and (4) with $Q = I_m$, respectively. Combining (35), (36) and definitions of $M$ and $z_k$, we obtain, for every $k \geq 1$,

$$
\|\tilde{z}_k - z_{k-1}\|_M^2 \leq \frac{1 + 2\alpha - \alpha^2}{\alpha^2} \|z_k - z_{k-1}\|_M^2 + \|z_k - z_{k-1}\|_M^2 = \frac{1 + 2\alpha}{\alpha^2} \|z_k - z_{k-1}\|_M^2.
$$
Now, letting $z^* := (x^*, y^*, \gamma^*)$ be an arbitrary solution of (13), we obtain from the last inequality and (1) with $Q = M$ that
\[
\|\tilde{z}_k - z_{k-1}\|^2_M \leq \frac{2(1 + 2\alpha)}{\alpha^2} \left[ \|z^* - z_k\|^2_M + \|z^* - z_{k-1}\|^2_M \right] \quad \forall k \geq 1.
\]
Since the generalized ADMM is an instance of the modified HPE framework with $\sigma := \sigma_\alpha$ (see Theorem 3.3 and (28)), it follows from the last inequality and Lemma A.1(b) that
\[
\|\tilde{z}_k - z_{k-1}\|^2_M \leq \frac{4(1 + 2\alpha)}{\alpha^2} \left[ \|z^* - z_0\|^2_M + \eta_0 \right] \quad \forall k \geq 1.
\]
Since $z^*$ is an arbitrary solution of (13), the result follows from the definition of $\rho_k$, $d_0$, and $\eta_0$ given in (11), (13), and (30), respectively.

Next result presents $O(1/k)$ convergence rate for the ergodic sequence associated to the generalized ADMM.

**Theorem 3.6. (Ergodic convergence of the generalized ADMM)** Let $\{(x_k, y_k, \gamma_k)\}$ be the sequence generated by the generalized ADMM and consider $\{\Delta x_k, \Delta y_k, \Delta \gamma_k\}$ as in (19). Define the ergodic sequences as
\[
(x_k^a, y_k^a, \gamma_k^a, \tilde{z}_k^a) := \frac{1}{k} \sum_{i=1}^{k} (x_i, y_i, \gamma_i, \tilde{z}_i), \quad (r_{k,x}^a, r_{k,y}^a, r_{k,\gamma}^a) := \frac{1}{k} \sum_{i=1}^{k} (\Delta x_i, \Delta y_i, \Delta \gamma_i),
\]
\[
\varepsilon_{k,x}^a = \frac{1}{k} \sum_{i=1}^{k} (H_1 \Delta x_i - A^* \tilde{z}_i, x_k^a - x_i),
\]
\[
\varepsilon_{k,y}^a = \frac{1}{k} \sum_{i=1}^{k} \left( H_2 + \frac{\beta}{\alpha} B^* B \right) \Delta y_i + \left( \frac{1 - \alpha}{\alpha} B^* \Delta \gamma_i - B^* \tilde{z}_i, y_k^a - y_i \right).
\]
Then, for every $k \geq 1$, there hold $\varepsilon_{k,x}^a \geq 0$, $\varepsilon_{k,y}^a \geq 0$, and
\[
0 \in M \left( \begin{array}{c} r_{k,x}^a \\ r_{k,y}^a \\ r_{k,\gamma}^a \end{array} \right) + \left( \begin{array}{ccc} \partial f_{x_{k,x}}(x_k^a) - A^* \tilde{z}_k^a \\ \partial g_{x_{k,y}}(y_k^a) - B^* \tilde{z}_k^a \\ A x_k^a + B y_k^a - b \end{array} \right),
\]
\[
\|(r_{k,x}^a, r_{k,y}^a, r_{k,\gamma}^a)\|_M \leq \frac{2\sqrt{c_a d_0}}{k}, \quad \varepsilon_{k,x}^a + \varepsilon_{k,y}^a \leq \tilde{c}_a \frac{d_0}{k},
\]
where
\[
c_a := \frac{\alpha + 4(2 - \alpha)\sigma_\alpha}{\alpha}, \quad \tilde{c}_a := \frac{3[3\alpha^2 + 4(1 + 2\alpha)\sigma_\alpha][\alpha + 4(2 - \alpha)\sigma_\alpha]}{2\alpha^3},
\]
and $M$, $d_0$, and $\sigma_\alpha$ are as in (17), (13), and (28), respectively.

**Proof.** It follows from Theorem 3.3 that the generalized ADMM is an instance of the modified HPE where $\{(z_k, \tilde{z}_k)\}$ is given by (29). Moreover, it is easy to see that the quantities $r_k^a$ and $\varepsilon_k^a$ given in (10) satisfy
\[
r_k^a = (r_{k,x}^a, r_{k,y}^a, r_{k,\gamma}^a), \quad \varepsilon_k^a = \frac{1}{k} \sum_{i=1}^{k} \left( \begin{array}{c} \Delta x_i \\ \Delta y_i \\ \Delta \gamma_i \end{array} \right),
\]
\[
\|r_k^a\|_M \leq \frac{2\sqrt{(\alpha + 4(2 - \alpha)\sigma_\alpha)d_0}}{k\sqrt{\alpha}}, \quad \varepsilon_k^a \leq \frac{3[3\alpha^2 + 4(1 + 2\alpha)\sigma_\alpha][\alpha + 4(2 - \alpha)\sigma_\alpha]d_0}{2\alpha^3 k},
\]
Hence, from Theorems 2.3 and definition of $\eta_0$ in (30), we have
\[
|\varepsilon_k^a| \leq \frac{3[3\alpha^2 + 4(1 + 2\alpha)\sigma_\alpha][\alpha + 4(2 - \alpha)\sigma_\alpha]d_0}{2\alpha^3 k},
\]
where in the last inequality we also used Lemma 3.3. Now, we claim that $\varepsilon_k^a = \varepsilon_k^{a,x} + \varepsilon_k^{a,y}$. Using this claim, (11) follows immediately from (12) and (14). Hence, to conclude the proof of the theorem, it just remains to prove the above claim. To this end, note that (35) and (39) yield

$$
\begin{align*}
\varepsilon_k^{a,x} + \varepsilon_k^{a,y} &= \frac{1}{k} \sum_{i=1}^{k} \left( \langle H_1 \Delta x_i, x_k^a - x_i \rangle + \left( H_2 + \frac{\beta}{\alpha} B^* B \right) \Delta y_i + \left( \frac{1-\alpha}{\alpha} B^* \Delta \gamma_i, y_k^a - y_i \right) \right) \\
&\quad + \frac{1}{k} \sum_{i=1}^{k} \langle A (x_k^a - x_i) + B (y_k^a - y_i), -\gamma_i \rangle.
\end{align*}
$$

(45)

On the other hand, from (37), we obtain

$$
\frac{1}{k} \sum_{i=1}^{k} \langle A (x_k^a - x_i) + B (y_k^a - y_i), -\gamma_i \rangle = \frac{1}{k} \sum_{i=1}^{k} \langle A x_k^a + B y_k^a - b - (A x_i + B y_i - b), \hat{\gamma}_k^a - \hat{\gamma}_i \rangle
$$

$$
= \frac{1}{k} \sum_{i=1}^{k} \langle -(A x_i + B y_i - b), \hat{\gamma}_k^a - \hat{\gamma}_i \rangle
$$

$$
= \frac{1}{k} \sum_{i=1}^{k} \left( \frac{1-\alpha}{\alpha} B \Delta y_i + \frac{1}{\alpha \beta} \Delta \gamma_i, \hat{\gamma}_k^a - \hat{\gamma}_i \right)
$$

where the last equality is due to (23). Hence, the claim follows by combining (45), and the definitions of $M$ and $\varepsilon_k^a$ in (17) and (33), respectively.

For a given tolerance $\varepsilon > 0$, Theorem 3.6 implies that in at most $O(1/\varepsilon)$ iterations of the G-ADMM, we obtain an "approximate" solution $(\hat{x}, \hat{y}, \hat{\gamma})$ and a residual $\hat{v} = (\hat{v}_1, \hat{v}_2, \hat{v}_3)$ of (3) satisfying

$$
\hat{v}_1 \in \partial_{\varepsilon_1} f(\hat{x}) - A^* \hat{\gamma}, \quad \hat{v}_2 \in \partial_{\varepsilon_2} g(\hat{y}) - B^* \hat{\gamma}, \quad \hat{v}_3 = A \hat{x} + B \hat{y} - b, \quad \|\hat{\gamma}\|_M^* \leq \varepsilon, \quad \varepsilon_1 + \varepsilon_2 \leq \varepsilon,
$$

where $\|\cdot\|_M^*$ is a dual norm (seminorm) associated to $M$.

## A Appendix (Proofs of Theorems 2.2 and 2.3)

The main goal in this section is to present the proofs of Theorems 2.2 and 2.3. Toward this goal, we first consider a technical lemma.

**Lemma A.1.** Let $\{(z_k, \tilde{z}_k, \eta_k)\}$ be the sequence generated by the modified HPE framework. For every $k \geq 1$, the following statements hold:

(a) for every $z \in Z$, we have

$$
\|z - z_k\|^2_M + \eta_k \leq (\sigma - 1)\|\tilde{z}_k - z_k\|^2_M + \|z - z_k\|^2_M + 2\langle M(z_k - z), z - \tilde{z}_k \rangle + \eta_{k-1};
$$

(b) for every $z^* \in T^{-1}(0)$, we have

$$
\|z^* - z_k\|^2_M + \eta_k \leq (\sigma - 1)\|\tilde{z}_k - z_k\|^2_M + \|z^* - z_k\|^2_M + \eta_{k-1} \leq \|z^* - z_k\|^2_M + \eta_{k-1}.
$$

**Proof.** (a) Note that, for every $z \in Z$,

$$
\|z - z_k\|^2_M - \|z - z_{k-1}\|^2_M = \|z - \tilde{z}_k\|^2_M - \|\tilde{z}_k - z_k\|^2_M = \|\tilde{z}_k - z_k\|^2_M - \|z - \tilde{z}_k\|^2_M + 2\langle M(z_k - z), z - \tilde{z}_k \rangle,
$$

which, combined with (35), proves the desired inequality.

(b) Since $M(z_{k-1} - z_k) \in T(\tilde{z}_k)$ and $0 \in T(z^*)$, we have $\langle M(z_k - z), z - z_k \rangle \geq 0$. Hence, the first inequality in (b) follows from (a) with $z = z^*$. Now, the second inequality in (b) follows from the fact that $\sigma \leq 1$. 

Proof of Theorem 2.2. The inclusion $0 \in M(z_k - z_{k-1}) + T(\tilde{z}_k)$ holds due to (7). It follows from (4) with $Q = M$ that, for every $j \geq 1$,

$$
\|z_j - z_{j-1}\|_M^2 \leq 2(\|\tilde{z}_j - z_{j-1}\|_M^2 + \|\tilde{z}_j - z_j\|_M^2) \leq 2(1 + \sigma)(\|\tilde{z}_j - z_{j-1}\|_M^2 + \eta_j - \eta_j)
$$

where the last inequality is due to (8). Now, if $z^* \in T^{-1}(0)$, we obtain from Lemma A.1(b)

$$(1 - \sigma)\|\tilde{z}_j - z_{j-1}\|_M^2 \leq \|z^* - z_{j-1}\|_M^2 - \|z^* - z_j\|_M^2 + \eta_j - \eta_j, \quad \forall j \geq 1.$$

Combining the last two inequality, we get

$$
(1 - \sigma)\sum_{j=1}^{k} \|z_j - z_{j-1}\|_M^2 \leq 2(1 + \sigma)\left(\|z^* - z_0\|_M^2 - \|z^* - z_k\|_M^2 + \eta_0 - \eta_k\right) + 2(1 - \sigma)(\eta_0 - \eta_k)
$$

\[ \leq 2(1 + \sigma)\|z^* - z_0\|_M^2 + 4\eta_0. \]

Hence, as $\sigma < 1$, we obtain

$$
\min_{i=1, \ldots, k} \|z_i - z_{i-1}\|_M^2 \leq \frac{1}{k(1 - \sigma)} (2(1 + \sigma)\|z^* - z_0\|_M^2 + 4\eta_0).
$$

Therefore, the desired inequality follows from the latter inequality and the definition of $d_0$ in (9). \hfill \Box

Proof of Theorem 2.3. The inclusion $0 \in Mr_k^a + T^{[\varepsilon_k^a]}(\tilde{z}_k)$ follows from (7), (10), and Theorems 2.1(a). Using (10), it is easy see that for any $z^* \in T^{-1}(0)$

$$
k r_k^a = z_k - z_0 = (z^* - z_0) + (z_k - z^*).$$

Hence, from inequality (4) with $Q = M$ and Lemma A.1(b), we have

$$
k^2\|r_k^a\|_M^2 \leq 2(\|z^* - z_0\|_M^2 + \|z^* - z_k\|_M^2) \leq 4(\|z^* - z_0\|_M^2 + \eta_0).
$$

Combining the above inequality with definition of $d_0$, we obtain the bound on $\|r_k^a\|_M$. Let us now to prove the bound on $\varepsilon_k^a$. From Lemma A.1(a), we have

$$
2 \sum_{i=1}^{k} \langle M(z_i - z_{i-1}), z - \tilde{z}_i \rangle \leq \|z - z_0\|_M^2 - \|z - z_k\|_M^2 + \eta_0 - \eta_k \leq \|z - z_0\|_M^2 + \eta_0,
$$

for every $z \in Z$. Letting $z = \tilde{z}_k^a$ and using (10), we get

$$
2k\varepsilon_k^a \leq \|\tilde{z}_k^a - z_0\|_M^2 + \eta_0 \leq \frac{1}{k} \sum_{i=1}^{k} \|\tilde{z}_i - z_0\|_M^2 + \eta_0 \leq \max_{i=1, \ldots, k} \|\tilde{z}_i - z_0\|_M^2 + \eta_0
$$

(46)

where the second inequality is due to convexity of the function $\|\cdot\|_M^2$, which also implies that, for every $i \geq 1$ and $z^* \in T^{-1}(0)$,

$$
\|\tilde{z}_i - z_0\|_M^2 \leq 3(\|\tilde{z}_i - z_i\|_M^2 + \|z^* - z_i\|_M^2 + \|z^* - z_0\|_M^2).
$$

Hence, using (8) and twice Lemma A.1(b), it follows, for every $i \geq 1$ and $z^* \in T^{-1}(0)$, that

$$
\|\tilde{z}_i - z_0\|_M^2 \leq 3(\|\tilde{z}_i - z_{i-1}\|_M^2 + \eta_{i-1} + \|z^* - z_{i-1}\|_M^2 + \eta_{i-1} + \|z^* - z_0\|_M^2) 
$$

\[ \leq 3(\sigma(\|\tilde{z}_i - z_{i-1}\|_M^2 + 2(\|z^* - z_{i-1}\|_M^2 + \eta_{i-1}) + \|z^* - z_0\|_M^2) 
$$

\[ \leq 3(\sigma(\|\tilde{z}_i - z_{i-1}\|_M^2 + 2\|z^* - z_0\|_M^2 + 2\eta_0),
$$
which, combined with (46) and definitions of $\rho_k$ in (11), yields
\[
2k\varepsilon_k^i \leq 3\left[3\|z^* - z_0\|^2_M + \sigma \rho_k\right] + 7\eta_0 \leq 3\left[3\|z^* - z_0\|^2_M + \eta_0 + \sigma \rho_k\right].
\]
Thus, the bound on $\varepsilon_k^i$ now follows from the definition of the $d_0$ in (3).

It remains to prove the second part of the theorem.
(a) if $\sigma < 1$, then it follows from Lemma A.1(b), for every $i \geq 1$ and $z^* \in T^{-1}(0)$, that
\[
(1 - \sigma)\|\tilde{z}_i - z_{i-1}\|^2_M \leq \|z^* - z_{i-1}\|^2_M + \eta_{i-1} \leq \|z^* - z_0\|^2_M + \eta_0.
\]
Hence, in view of definitions of $\rho_k$ and $d_0$, we obtain (12).
(b) If $\text{Dom} T$ is bounded, then it follows from inequality (41) with $Q = M$, and Lemma A.1(b), for every $i \geq 1$ and $z^* \in T^{-1}(0)$, that
\[
\|\tilde{z}_i - z_{i-1}\|^2_M \leq 2\left[\|z^* - z_{i-1}\|^2_M + \|\tilde{z}_i - z^*\|^2_M\right] \leq 2\left[\|z^* - z_0\|^2_M + \eta_0 + D\right]
\]
which, combined with definitions of $\rho_k$ and $d_0$, proves the desired result. □
