The well-known results concerning a dilute Bose gas with the short-range repulsive interaction should be reconsidered due to a thermodynamic inconsistency of the method being basic to much of the present understanding of this subject and nonrelevant behaviour of the pair distribution function at small boson separations. The aim of our paper is to propose a new way of treating the dilute Bose gas with an arbitrary strong interaction. Using the reduced density matrix of the second order and a variational procedure, this way allows us to escape the inconsistency mentioned and operate with singular potentials like the Lennard-Jones one. All the consideration concerns the zero temperature.

I. INTRODUCTION AND BASIC EQUATIONS

It is well-known that to investigate a dilute Bose gas of particles with an arbitrary strong repulsion (the strong-coupling regime), one should go beyond the Bogoliubov approach (the weak-coupling case) and treat the short-range boson correlations in a more accurate way. An ordinary manner of doing so is the use of the goliubov approach (the weak-coupling case) and treating the strong-coupling regime, one should go beyond the Bogoliubov method.

The 2-matrix for the many-body system of spinless bosons can be represented as [3]:

\[ \rho_2(r_1',r_2';r_1,r_2) = \frac{F_2(r_1,r_2;r_1',r_2')}{N(N-1)}, \]

where the pair correlation function is given by

\[ F_2(r_1,r_2;r_1',r_2') = \langle \psi^\dagger(r_1)\psi^\dagger(r_2)\psi(r_2')\psi(r_1') \rangle. \]

Here \( \psi(r) \) and \( \psi^\dagger(r) \) denote the boson field operators. Recently it has been found [4] that for the uniform system with a small depletion of the zero-momentum state and concerns the reduced density matrix of the second order (the 2-matrix) and is based on the variational method.

The 2-matrix for the many-body system of spinless bosons can be represented as [3):

\[ \rho_2(r_1',r_2';r_1,r_2) = \frac{F_2(r_1,r_2;r_1',r_2')}{N(N-1)}, \]

where the pair correlation function is given by

\[ F_2(r_1,r_2;r_1',r_2') = \langle \psi^\dagger(r_1)\psi^\dagger(r_2)\psi(r_2')\psi(r_1') \rangle. \]

Having in our disposal the distribution function \( n_k \) and the set of the pair wave functions \( \varphi(r) \) and \( \varphi_p(r) \), we are able to calculate the main thermodynamic quantities of the system of interest. In particular, the mean energy per particle is expressed in terms of \( n_k \) and \( g(r) \) via the well-known formula:

\[ \varepsilon = \int \frac{d^3k}{(2\pi)^3} \frac{n_k}{n} + \frac{n}{2} \int g(r) \Phi(r) d^3r, \]

where \( T_k = \hbar^2 k^2/2m \) is the one-particle kinetic energy, \( n = N/V \) stands for the boson density and the relation

\[ g(r) = F_2(r_1,r_2;r_1,r_2)/n^2. \]
 II. THE BOGOLIUBOV MODEL

The starting point of our investigation is the weak-coupling regime which implies weak spatial correlations of particles and, thus, is characterized by the set of the inequalities

$$|\psi(r)| \ll 1, \quad |\psi_p(r)| \ll 1.$$  

(9)

Specifically, the Bogoliubov model corresponds to the choice

$$|\psi(r)| \ll 1, \quad \psi_p(r) = 0.$$  

(10)

Besides, owing to a small depletion of the Bose condensate $(n - n_0)/n$ we have for the one-particle density matrix $F_1(r) = \langle \psi^\dagger(r_1)\psi(r_2) \rangle$:

$$\left| F_1(r) \right| = \left| \int \frac{d^3k}{(2\pi)^3} \frac{n_k}{n} \exp(ikr) \right| \leq \frac{n-n_0}{n} \ll 1.$$  

So, investigating the Bose gas within the Bogoliubov scheme, we have two small quantities: $\psi(r)$ and $F_1(r)/n$. This enables us to write Eq. (8) with the help of (3) as follows:

$$g(r) = 1 + 2\psi(r) + \frac{2}{n} \int \frac{d^3k}{(2\pi)^3} n_k \exp(ikr),$$  

(11)

where we restricted ourselves to the terms linear in $\psi(r)$ and $F_1(r)/n$ and put $\psi^* = \psi$ because the pair wave functions can be chosen as real quantities. Equations for $\psi(k)$ and $n_k$ can be found varying the mean energy (7) under the conditions (11) and (12). Inserting Eq. (11) into Eq. (6) and, then, varying the obtained expression, we arrive at

$$\delta \varepsilon = \int \frac{d^3k}{(2\pi)^3} \left\{ \left( T_k + n\Phi(k) \right) \frac{\delta n_k}{n} + n\Phi(k)\delta\bar{\psi}(k) \right\}.$$  

(16)

Relation (12) connecting $\bar{\psi}(k)$ with $n_k$ results in

$$\delta\bar{\psi}(k) = \frac{(2n_k + 1)\delta n_k}{2n_0^2\bar{\psi}(k)} + \frac{\bar{\psi}(k)}{n_0}\int \frac{d^3q}{(2\pi)^3} \delta n_q,$$  

(17)

where the equality

$$n = n_0 + \int \frac{d^3k}{(2\pi)^3} n_k,$$  

(18)

is taken into consideration. Setting $\delta \varepsilon = 0$ and using Eqs. (14) and (13), we derive the following expression:

$$-2T_k\bar{\psi}(k) = \frac{n^2}{n_0^2} \Phi(k)(1 + 2n_k) + 2n_k \bar{\psi}(k)$$

$$\times \left( \Phi(k) + \frac{n}{n_0} \int \frac{d^3q}{(2\pi)^3} \Phi(q)\bar{\psi}(q) \right).$$  

(19)

Here one should realize that Eq. (19) is able to yield results being accurate only to the leading order in $(n - n_0)/n$ because the used expression for $g(r)$ given by Eq. (14) is valid to the next-to-leading order \[\text{[8]}\]. So, Eq. (19) should be rewritten as

$$-2T_k\bar{\psi}(k) = \Phi(k)(1 + 2n_k) + 2n_k \bar{\psi}(k).$$  

(20)

Equation (20) is an equation of the Bethe-Goldstone type or, in other words, the in-medium Schrödinger equation for the pair wave function. As $2\Phi(k)(n_k + n\bar{\psi}(k))$ is the product of the Fourier transforms of $\Phi(r)$ and $n(g(r) - 1)$, we can rewrite Eq. (20) in the more customary form

$$\frac{\hbar^2}{m} \nabla^2 \varphi(r) = \Phi(r) + n \int \Phi(|r - y|) \left( g(y) - 1 \right) d^3y.$$  

(21)

The structure of Eq. (21) is discussed in the papers \[\text{[9]}\]. Here we only remark that the right-hand side (r.h.s.) of Eq. (21) is the in-medium potential of the boson-boson interaction in the weak-coupling approximation. The system of equations (12) and (21) can easily be solved, which leads to the familiar results \[\text{[1]}\]:

$$n_k = v_k^2, \quad \bar{\psi}(k) = u_kv_k/n_0.$$  

(22)

With Eqs. (14) and (13) one can readily obtain Eq. (12). Now, let us show that all the results on the thermodynamics of a weak-coupling Bose gas can be derived for the Bogoliubov scheme with variation of the mean energy (7) under the conditions (11) and (12). Inserting Eq. (11) into Eq. (6) and, then, varying the obtained expression, we arrive at
III. A DILUTE BOSE GAS WITHIN THE
BOGOLIUBOV MODEL

As it was mentioned, the aim of our paper is investi-
gation of the case of a dilute Bose gas with an arbitrary
strong repulsion between bosons. So, considering a di-
lute Bose gas in the weak-coupling approximation can
be a good exercise providing us with useful information. Let
us investigate the thermodynamics of a dilute Bose gas
within the Bogoliubov model. With Eqs. (11), (13) and
5 we derive
\[
\varepsilon = \frac{n}{2} \Phi(0) + \frac{1}{2n} \int \frac{d^3k}{(2\pi)^3} \times \left( \sqrt{T_k^2 + 2nT_k \Phi(k) - T_k - n\Phi(k)} \right).
\]
(23)
The well-known argument of Landau (see the footnote
in Ref. [1] and discussion in Ref. [2]) testifies that the
properties of dilute quantum gases are ruled by the scat-
tering length. Within the Bogoliubov model this length
is usually assumed to be equal to \(m\Phi(0)/4\pi\hbar^2\). If so,
when expanding \(\varepsilon\) in powers of the boson density \(n\), one
could replace \(\Phi(k)\) by \(\Phi(0)\) in Eq. (23), introducing
the low-momentum approximation. However, this leads to
a divergence because at large \(k\) the integral behaves as
\(-n^2\Phi^2(k)/2T_k\). To properly calculate the integral in
Eq. (24), we should rewrite Eq. (24) in the following form:
\[
\varepsilon = \frac{n}{2} \Phi(0) - \int \frac{d^3k}{(2\pi)^3} \frac{\Phi^2(k)}{2T_k} + I,
\]
(24)
where
\[
I = \frac{1}{2n} \int_0^\infty dk \frac{4\pi k^2}{(2\pi)^3} \times \left( \sqrt{T_k^2 + 2nT_k \Phi(k) - T_k - n\Phi(k)} + \frac{n^2\Phi^2(k)}{2T_k} \right).
\]
(25)
Now, substituting \(k = (2mny)^{1/2}/\hbar\) in the integral, we
obtain the expression
\[
I = \frac{\sqrt{2}}{4\pi^2} \left( \frac{mn}{\hbar^2} \right)^{3/2} \int_0^\infty dy \left\{ y \sqrt{y + 2\Phi(\sqrt{2mny}/\hbar)} - y^{3/2} - \Phi(\sqrt{2mny}/\hbar) y^{1/2} + \frac{\Phi^2(\sqrt{2mny}/\hbar)}{2\sqrt{y}} \right\}
\]
(26)
which at sufficiently small \(n\) may be rewritten as
\[
I = \frac{\sqrt{2}}{4\pi^2} \left( \frac{mn}{\hbar^2} \right)^{3/2} \int_0^\infty dy \left\{ y \sqrt{y + 2\Phi(0)} - y^{3/2} - \Phi(0) y^{1/2} + \frac{\Phi^2(0)}{2\sqrt{y}} \right\}.
\]
The derived integral is readily calculated. The result is
given by
\[
I = \frac{8}{15\pi^2} \left( \frac{mn}{\hbar^2} \right)^{3/2} \Phi^{5/2}(0).
\]
(27)
In turn, the first term in the r.h.s. of Eq. (24) can be
represented as
\[
n \frac{1}{2} \Phi(0) - \int \frac{d^3k}{(2\pi)^3} \frac{\Phi^2(k)}{2T_k} = n \int \frac{\varphi^{(0)}(r)\Phi(r)d^3r},
\]
(28)
where \(\varphi^{(0)}\) is the solution of Eq. (21) in the limit \(n \rightarrow 0\).
This is nothing else but the Schrödinger equation in the
Born approximation. According to the relations (25) and
(28) we have to conclude that the scattering length in the
case of interest is expressed in the form
\[
a_B = \frac{m}{4\pi \hbar^2} \int \varphi^{(0)}(r)\Phi(r)d^3r.
\]
(29)
One can easily be convinced that \(\Phi(0)\) cannot be repres-
ted only in terms of \(a_B\) and, hence, the dependence on the shape of the interaction potential appears in the
series expansion for the mean energy in the first correc-
tion to the term \(2\pi\hbar^2a_Bn/m\). To rewrite our result for \(\varepsilon\) in a graphic form, we introduce one more characteristic
length \(b > 0\) which obeys the relation
\[
b = -\frac{m}{4\pi \hbar^2} \int \psi^{(0)}(r)\Phi(r)d^3r = \frac{m}{4\pi \hbar^2} \int \frac{d^3k}{(2\pi)^3} \frac{\Phi^2(k)}{2T_k},
\]
(30)
where \(\psi^{(0)}(r) = \varphi^{(0)}(r) - 1\). Further, with the help of
Eqs. (21), (28), we arrive at
\[
\varepsilon = \frac{2\pi \hbar^2 a_B n}{m} \left\{ 1 + \frac{128}{15\sqrt{\pi}} \frac{n\Phi(0)}{\hbar^2} \left( 1 + \frac{5b}{2a_B} \right) + \cdots \right\},
\]
(31)
here the condition \(b \ll a_B\) is of use. It is not difficult
to see that the expression (25) taken with negative sign
is the next correction to the scattering length calculated
within the Born approximation. As to the Eq. (27), it is
related to the next-to-Born approximation. Stress that in
the Bogoliubov model the energy term \(n\Phi(0)/2\) is treated
as the major one [1], which implies that the condition
\(b \ll a_B\) is fulfilled. This qualitative criterion can be
written as
\[
\Phi(0) \gg \int \frac{d^3k}{(2\pi)^3} \frac{\Phi^2(k)}{2T_k}.
\]
Beyond this inequality the model may be thermodynamically unstable. In particular, the opposite case

$$\Phi(0) < \int \frac{d^3q}{(2\pi)^3} \frac{\tilde{\Phi}^2(k)}{2T_k}$$

leads to the negative scattering length $^{(27)}$ which at sufficiently low densities results in $-\partial^2 E/\partial V^2 = \partial p/\partial V > 0$.

Thus, investigated within the Bogoliubov model, the thermodynamics of a dilute Bose gas is ruled by the scattering length only in the zero-density limit. While the next-to-leading term in the series expansion given by Eq. $(29)$ depends on the shape of the interaction, which is expressed in appearance of the additional characteristic length $b$. This conclusion differs from the results of papers [2] according to which the series expansion for $\varepsilon$ taken to the same order as that of Eq. $(29)$, is fully determined by the scattering length. To clarify the situation concerning this difference, we should go to the strong-coupling regime.

**IV. THE STRONG-COUPLING REGIME**

Now, after the detailed investigations of the Bogoliubov model within the scheme proposed, we are able to demonstrate that the investigation of the strong-coupling case based on the Bogoliubov model with the effective boson-boson interaction, results in a loss of the thermodynamic consistency. Indeed, as it was shown in the previous section, any calculating scheme using the basic relations of the Bogoliubov model $(11), (12)$ conclusively leads to Eqs. $(20)-(22)$ provided this scheme does yield the minimum of the mean energy. In this case Eqs. $(20)-(22)$ certainly includes the quantity $\Phi(r)$ which is the “bare” interaction potential appearing in Eq. $(1)$. The use of the Bogoliubov model with the effective interaction potential substituted for $\Phi(r)$ can in no way disturb the relations given by Eqs. $(11)$ and $(12)$. And Eq. $(9)$ is the same in both the weak- and strong-coupling regimes. Thus, any attempts of replacing $\Phi(r)$ by the effective “dressed” potential without modifications of Eqs. $(11)$ and $(12)$ results in a calculating procedure which does not really provide the minimum of the mean energy. It is nothing else but a loss of the thermodynamic consistency. We remark that we do mean, of course, that the $t$-matrix approach or the pseudopotential method can not be applied in the quantum scattering problem. It is only stated that the usual way of combining the ladder diagrams with the random phase approximation faces the trouble mentioned above. Though our present investigation is limited to the consideration of the many-boson systems, the derived result gives a hint that the similar situation is likely to take place in the Fermi case, too. In this connection it is worth noting the problem associated with the lack of consistency of the standard method of treating the dilute Fermi gas [3].

The strong-coupling regime is characterized by significant spatial correlations. So, Eq. $(10)$ resulting in Eq. $(11)$ is not relevant for an arbitrary strong repulsion between bosons at small separations when we have $\psi(0) = -1, \psi_p(0) = -\sqrt{2}$ (see Refs. $(21)$). Therefore, to investigate the strong-coupling regime, Eq. $(11)$ should be abandoned in favor of Eq. $(3)$. Expression $(3)$ is accurate to the next-to-leading order in $(n_n-n_0)/n$. So, using Eqs. $(3)$ and $(4)$, we can write

$$g(r) = \varphi^2(r) + \frac{2}{n} \int \frac{d^3q}{(2\pi)^3} n_q \left( \varphi_{a/2}^2(r) - \varphi^2(r) \right). \quad (31)$$

Let us now perturb $\tilde{\psi}(k)$ and $n(k)$. Working to the first order in the perturbation and keeping in mind conditions $(22)$ and $(31)$, from Eq. $(5)$ we derive

$$-2T_k\tilde{\psi}(k) = \tilde{U}(k)(1 + 2n_k) + 2n\tilde{\psi}(k)\tilde{U}'(k) \quad (32)$$

with

$$\tilde{U}(k) = \int \varphi(r)\Phi(r)\exp(-ikr)d^3r \quad (33)$$

and

$$\tilde{U}'(k) = \int \left( \varphi_{a/2}^2(r) - \varphi^2(r) \right) \Phi(r) d^3r. \quad (34)$$

Using Eqs. $(33), (34)$ as well as the relation $\psi_k(r) \rightarrow \sqrt{2}\psi(r)$ $(k \rightarrow 0)$ (see the boundary conditions $(3), (4)$), we obtain $\tilde{U}(0) \neq \tilde{U}'(0)$. This implies that the system of Eqs. $(12)$ and $(22)$ is not able to yield the relation $n_k \propto 1/k$ $(k \rightarrow 0)$ following from the $1/k$ theorem of Bogoliubov for the zero temperature $(11)$. Indeed, let us assume $n_k \propto \infty$ for $k \rightarrow 0$. Then, from Eq. $(12)$ at $n = n_0$, we find $n/\psi(k)/n_k \rightarrow 1$ when $k \rightarrow 0$. On the contrary, Eq. $(22)$ gives $n/\psi(k)/n_k \rightarrow U(0)/U'(0) \neq 1$ for $k \rightarrow 0$. So, consideration of the Bose gas based on Eqs. $(3)$ and $(22)$ does not produce satisfactory results. Nevertheless, it is worth noting that Eq. $(22)$ has an important peculiarity which differentiate it from Eq. $(20)$ in an advantageous way. The point is that in both the limits $n \rightarrow 0$ and $k \rightarrow \infty$ Eq. $(22)$ is reduced to

$$-\frac{\hbar^2}{m} \nabla^2 \varphi(r) + \Phi(r)\varphi(r) = 0. \quad (35)$$

As it is seen, this is the exact “bare” (not in-medium) Schrödinger equation, other than its Born approximation following from Eq. $(21)$. Thus, we can expect the line of our investigation to be right.

As it was shown in the previous paragraph, an approach adequate for a dilute Bose gas with an arbitrary strong interaction can not be constructed without modifications of Eq. $(12)$. This is also in agreement with a consequence of the relation

$$|\langle a_k a_{-k} \rangle|^2 \leq \langle a_k a_{k} \rangle \langle a_{-k} a_{-k} \rangle \quad (36)$$
resulting from the inequality of Cauchy-Schwarz-Bogoliubov

\[ |\langle \hat{A}\hat{B} \rangle| \leq \langle \hat{A} \hat{A}^{\dagger} \rangle \langle \hat{B} \hat{B}^{\dagger} \rangle. \]

With Eqs. (38) and (39) one can easily derive \( n_{k} \tilde{\psi}^{2}(k) \leq n_{k}(n_{k}+1) \). Thus, it is reasonable to assume that Eq. (12) takes into account only the condensate-condensate channel and ignores the supracondensate-condensate ones. Now the question arises how to find corrections to the r.h.s. of Eq. (12). At present we have no regular procedure allowing us to do this in any order of \((n-n_{0})/n\). However, there exists an argument which makes it possible to realize the first step in this direction. The matter is that the alterations needed to produce the equation for \( \tilde{\psi}_{0}(k) \) which is reduced to the equation for \( \psi(k) \) in the limit \( p \to 0 \). Though this requirement does not uniquely determine the corrections to Eq. (12), it turns out to be significantly restrictive. In particular, even the simplest variant of correcting Eq. (12) in this way, leads to promising results. Indeed, this variant is specified by the expression

\[ n_{k}(n_{k}+1) = n_{0}^{2} \tilde{\psi}^{2}(k) + 2n_{0} \int \frac{d^{3}q}{(2\pi)^{3}} n_{q} \tilde{\psi}_{q/2}^{2}(k). \]  

Eq. (32) is valid to the next-to-leading order in \((n-n_{0})/n\). So, we may rewrite it as

\[ n_{k}(n_{k}+1) = n_{0}^{2} \tilde{\psi}^{2}(k) + 2n \int \frac{d^{3}q}{(2\pi)^{3}} n_{q} \left( \tilde{\psi}_{q/2}^{2}(k) - \tilde{\psi}^{2}(k) \right). \]  

Eq. (38)

Perturbing \( \tilde{\psi}(k) \) and \( n_{k} \) and bearing in mind conditions (21) and (28), Eq. (1) gives Eq. (32) again. However, now \( U'(k) \) obeys the new relation

\[
U'(k) = \int \left( \varphi_{k/2}^{2}(r) - \varphi^{2}(r) \right) \Phi(r) \, dr
- \int \frac{d^{3}q}{(2\pi)^{3}} \frac{\tilde{U}(q)(\tilde{\psi}_{k/2}^{2}(q) - \tilde{\psi}^{2}(q))}{\psi(q)} \]  

(39)

which significantly differs from Eq. (34). Indeed, the choice of the pair wave functions as real quantities implies that operating with integrands in Eqs. (33) and (34), one can exploit \( \varphi_{k}^{2}(r) - \sqrt{2}\varphi(r) \propto r^{2} \) at small \( p \). For \( k \to 0 \) this provides \( \tilde{U}'(k) - \tilde{U}(k) = t_{k} = c k^{4} + \cdots \). Note that for \( k \to \infty \) we have \( t_{k} \to -\tilde{U}(0) \). Similar to Eq. (20), Eq. (32) can yields results correct only to the leading order in \((n-n_{0})/n\). So, it has to be solved together with Eq. (12) where \( n_{k}^{2} \) should be replaced by \( n^{2} \), rather than with Eq. (32). This leads to the following relations:

\[ n_{k} = \frac{1}{2} \left( \frac{\tilde{T}_{k} + n\tilde{U}(k)}{\sqrt{\tilde{T}_{k}^{2} + 2nT_{k}\tilde{U}(k)}} - 1 \right), \]  

(40)

\[ \tilde{\psi}(k) = -\frac{\tilde{U}(k)}{2\sqrt{\tilde{T}_{k}^{2} + 2nT_{k}\tilde{U}(k)}} \]  

(41)

where \( \tilde{T}_{k} = T_{k} + nt_{k} \), with the limit \( \tilde{T}_{k}/T_{k} \to 1 \) as \( k \to \infty \).

For \( k \to 0 \) Eq. (10) gives \( n_{k} \approx (\sqrt{n}m\tilde{U}(0)/\hbar k - 1)/2 \), which is fully consistent with the “1\( k^{2}\) theorem of Bogoliubov for the zero temperature [10].

As it is seen, the strong-coupling regime is more complicated than the Bogoliubov one because we do not know the quantity \( \tilde{U}(k) \) ab initio. To find it, one should solve Eqs. (12) and (41) in a self-consistent manner. Equations (23) and (41) lead to one more interesting relation

\[ \tilde{U}(k) = \Phi(k) - \frac{1}{2} \int \frac{d^{3}q}{(2\pi)^{3}} \frac{\tilde{U}(\Phi(k) - \Phi(q))}{\sqrt{T_{q}^{2} + 2nT_{q}\tilde{U}(q)}} - I_{1}, \]  

(42)

where for \( I_{1} \) we have

\[ I_{1} = \frac{1}{2} \int \frac{d^{3}q}{(2\pi)^{3}} \left\{ \frac{\tilde{U}(\Phi(k) - \Phi(q))}{\sqrt{T_{q}^{2} + 2nT_{q}\tilde{U}(q)}} - \frac{\tilde{U}(\Phi(k) - \Phi(q))}{T_{q}} \right\}. \]

Operating with \( I_{1} \) in the same manner as we dealt with \( I \) in the section II and taking into account that \( t_{k} = 0 \) at \( k = 0 \), for \( n \to 0 \) we derive

\[ I_{1} = -\alpha \Phi(k), \quad \alpha = \sqrt{\frac{nm}{\pi^{2}h^{4}}} \tilde{U}(3/2)(0). \]  

(43)

From Eqs. (12) and (43) it now follows that

\[ \tilde{U}(k) - \tilde{U}(0)(k) = \alpha \Phi(k) - \int \frac{d^{3}q}{(2\pi)^{3}} \frac{\tilde{U}(\Phi(k) - \Phi(q))}{2T_{q}} \times \left( \tilde{U}(q) - \tilde{U}(0)(q) \right). \]  

(44)

Here \( \tilde{U}(0)(k) = \int \varphi(0)(r)\Phi(0) \exp(-i\mathbf{k}\mathbf{r}) d^{3}r \) but now \( \varphi(0)(r) \) obeys Eq. (13) rather than Eq. (2) taken in the limit \( n \to 0 \) like in the section II. Let us introduce the new quantity \( \xi(q) = -(\tilde{U}(q) - \tilde{U}(0)(q))/2T_{q} \). Then, for its Fourier transform \( \xi(r) \) we obtain

\[ -\frac{m}{n} \nabla^{2} (\alpha + \xi(r)) + \Phi(r) (\alpha + \xi(r)) = 0, \]

(45)

here \( \xi(r) \to 0 \) when \( r \to \infty \). Comparing Eq. (45) with Eq. (55), we find \( \xi(r) = \alpha \psi(0)(r) \). Hence, for \( n \to 0 \) we have
of the grand canonical potential, and relation (see Ref. [14], where $a$ is the scattering length.

Having in our disposal Eq. (40), we are able to calculate the expansion in powers of $n$ for the condensate depletion and energy of a dilute Bose gas with an arbitrary strong interparticle potential. Considering the condensate depletion $(n - n_0)/n = 1/(2\pi^3) \int_0^\infty dk 4\pi k^2 n_k/n$, with the help of Eq. (40) we obtain

$$\frac{n - n_0}{n} = \frac{8}{3\sqrt{\pi}} \sqrt{na^3} + \cdots.$$  

(47)

Notice that according to Eq. (46), one can expect that among the omitted terms in Eq. (47) there is one proportional to $na^3$.

The most simple way of deriving the expansion for the mean energy per particle is based on using the chemical potential which, in the presence of the Bose condensate, is given by

$$\mu = \frac{1}{\sqrt{n_0}} \int d^3 r' \Phi(|r - r'|)(\psi^\dagger(r')\psi(r')).$$  

(48)

This formula follows from the well-known expression $\delta\Omega = (\delta (\hat{H} - \mu \hat{N}))$, where $\delta\Omega$ is an infinitesimal change of the grand canonical potential, and relation (see Ref. [10])

$$\frac{\partial \Omega(N_0, \mu, T)}{\partial N_0} = 0.$$

Using the specific expressions for the scattering parts of the condensate-condensate and supracondensate-condensate pair wave functions [1] given by Eqs. (15) and (24) one can represent Eq. (48) in the following form:

$$\mu = n_0 \bar{U}(0) + \sqrt{2} \int \frac{d^3 q}{(2\pi)^3} n_q \bar{U}_q/2(q/2),$$  

(49)

here

$$\bar{U}_q(k) = \int \varphi_p(r)\Phi(r) \exp(-ikr)d^3 r.$$  

Now, for $n \to 0$ (see the procedure of calculating the integral $I$ in the section II) one can rewrite Eq. (49) as

$$\mu = n \bar{U}(0) \left(1 + \frac{n - n_0}{n} + \cdots\right).$$  

(50)

Inserting Eqs. (46) and (47) into Eq. (50), we arrive at

$$\mu = \frac{4\pi}m \frac{\hbar^2 a n}{3\sqrt{\pi}} \left(1 + \frac{32}{3\sqrt{\pi}} \sqrt{na^3} + \cdots\right).$$  

(51)

This result for the chemical potential implies, due to the basic thermodynamic formula $\mu = \partial (<c_n>/\partial n)$, the following expansion for the mean energy per particle:

$$\varepsilon = \frac{2\hbar^2 a n}{m} \left(1 + \frac{128}{15\sqrt{\pi}} \sqrt{na^3} + \cdots\right).$$  

(52)

As it is seen, the relation (52) coincides with the well-known result of the approach [1] being reduced to the Bogoliubov model with the “dressed” interaction. It is not a surprise because according to the conclusions of the section II, we know that the numerical factor $128/(15\sqrt{\pi})$ appears in the series expansion for the mean energy per particle within the Bogoliubov model (see Eq. (23)). Replacing the bare interaction potential by the “dressed” one results in replacing the scattering length $a_B$ in Eq. (23) by its exact value $a$. The only problem of doing so concerns the parameter $b$. Indeed, it follows from Eq. (25) that substituting the hard-sphere potential $U(0) = 4\pi \hbar^2 a/m$ for $\Phi(k)$ leads to the familiar divergence (see, e.g. Ref. [8] p. 314). This obstacle has been overcome with the help of the well-known argument of Landau (see the footnote in the paper [1]) stating that the thermodynamics of dilute quantum gases is only ruled by the vacuum scattering amplitude. According to this reasoning one can expect that dependence on the shape of the interaction potential should not appear in the first orders of the density series expansion of the thermodynamic quantities. So, various regularizing procedures, more or less speculative, have been worked out in order to exclude this divergence (together with the parameter $b$). On the contrary, there are no problems like this within the approach of the present paper. Here Eq. (52) is derived on the solid theoretical basis rather than with the help of Landau’s argument. In spite of its reasonable character, it needed to be corroborated, and the results of this paper given by Eqs. (47), (48) and (52) have proved the validity of Landau’s argument beyond any inconsistencies and divergencies. In the weak-coupling case when $|\Phi(r)| \ll 1$, the energy per particle calculated within our scheme is expressed by Eq. (52) with $a$ replaced by $a_B$. So, the appearance of the parameter $b$ in the results of the section II is an artifact following from the neglect of scattering in the supracondensate-condensate pair wave channel.

The divergence mentioned in the previous paragraph is not typical of the strong-coupling perturbation theory for the many-boson systems but results from, say, the weak-coupling spirit of the approach of Ref. [1]. A simple way to be convinced of this is to consider the spatial boson correlations. Taken to the lowest-order with respect to the density, the structural factor (see the last paper in Ref. [1]) is of the form

$$S(k) = \frac{T_k}{\sqrt{T_k^2 + 2nT_k\bar{U}(0)}}.$$  

(53)

By definition we have
$$g(r) = 1 + \frac{1}{n} \int \frac{d^3 k}{(2\pi)^3} (S(k) - 1) \exp(i kr).$$

(54)

Using Eqs. (53) and (54), for $n \to 0$ one can readily find

$$g(r) \to 1 + 2\psi^{(0)}(r),$$

(55)

where $\psi^{(0)}(r)$ obeys Eq. (53). This result answers the approximation (11) while $\psi^{(0)}(r)$ is not related to the weak-coupling regime and obeys the exact “bare” Schrödinger equation. In the situation $\Phi(r) \to \infty$ for $r \to 0$ one has $\psi^{(0)}(r = 0) = -1$, which implies, according to Eq. (55),

$$g(r = 0) \to -1$$

for $n \to 0$. It is not consistent with the physical sense of $g(r)$ and has nothing to do with the strong-coupling case corresponding to Eq. (51) when for $n \to 0$

$$g(r) \to \left( 1 + \psi^{(0)}(r) \right)^2.$$  

Notice that the zero-density limits for the thermodynamic quantities of a strongly interacting dilute Bose gas were first found in the Bogoliubov original paper [1]:

$$(n - n_0)/n \to 0, \ g(r) \to (\psi^{(0)}(r))^2, \ z/n \to \tilde{U}^{(0)}(0)/2.$$

At last, we remark that due to the incorrect picture of the spatial boson correlations found in papers [2], one can expect significant alterations for the spectrum of the elementary excitations too. However, to clarify these corrections we should conclusively solve the problem concerning relation between the momentum distribution and scattering parts of the pair wave functions. Indeed, it has been mentioned that there exist various possibilities of generalizing Eq. (12) so as to obtain the equation for $\tilde{\psi}_p(k)$ being reduced to the equation for $\tilde{\psi}(k)$ in the limit $p \to 0$. These possibilities result in the same series expansions for the thermodynamic quantities [7], [1] and [12] but produce different data for the long-range spatial boson correlations. Here we limited ourselves to considering the most simple variant of generalizing Eq. (12), which makes it possible to investigate only the thermodynamics of a strongly interacting Bose gas. The interesting and important problem of the spectrum of the elementary excitations is thus beyond the scope of this paper and will be the subject of the future investigations.

V. CONCLUSION

Concluding let us take notice of the important points of this paper once more. It was demonstrated that thermodynamically consistent calculations based on Eqs. (11) and (12) conclusively result in Eqs. (20)-(22). Therefore, using the Bogoliubov model with the “dressed” interaction does not provide the satisfactory solution of the problem of the strong-coupling Bose gas. As it was shown, when investigating this subject, one should go beyond the Bogoliubov scheme. To do this, we developed the approach reduced to the system of Eqs. (13), (14), (12) and (11). These equations leading to the in-medium Lippmann-Schwinger equation (12), reproduce the familiar results (17), (24) and (22) for the condensate depletion, chemical potential and mean energy but yield completely different picture of the spatial boson correlations. This difference should manifest itself in the next orders of the density series expansions for the thermodynamic quantities and in the excitation spectrum as well.

[9] From the relation $\lim_{p \to 0} \psi_p(r) = \sqrt{2} \psi(r)$ an interesting limit can be derived with the help of Eqs. (10) and (11): $\lim_{p \to 0} \lim_{V \to \infty} \sqrt{V} (a_{2p}^\dagger a_{2p+k} a_{2p-k})/n_{2p} = 2(a_k a_{-k})/\sqrt{n_0}$.

[11] It is not true in the case of complex-value wave functions. However, in this situation integrands in Eqs. (43) and (49) would include the absolute values of $\tilde{\psi}(k)$ and $\psi_p(k)$ for which we have $|\tilde{\psi}_p(k)| - \sqrt{2}|\tilde{\psi}(k)| \times p^2$ at small $p$ in the case of the boundary conditions (10).
