VARIATIONS OF RATIONAL HIGHER TANGENTIAL STRUCTURES

HISHAM SATI AND MATTHEW WHEELER

Abstract. The study of higher tangential structures, arising from higher connected covers of Lie groups (String, Fivebrane, Ninebrane structures), require considerable machinery for a full description, especially for connections to geometry and applications. With utility in mind, in this paper we study these structures at the rational level and by considering Lie groups as a starting point for defining each of the higher structures, making close connection to $p_i$-structures. We indicatively call these (rational) Spin-Fivebrane and Spin-Ninebrane structures. We study the space of such structures and characterize their variations, which reveal interesting effects whereby variations of higher structures are arranged to systematically involve lower ones. We also study the homotopy type of the gauge group corresponding to bundles equipped with the higher rational structures that we define.

1. Introduction

Manifolds have been classically studied through structures associated with their tangent bundles leading to characterizations via obstruction theory and characteristic classes [St99][MS74][Hu94]. We examine the rationalization of tangential structures, with an emphasis on structures arising from higher connected covers of Lie groups. That is, we consider rationalizing the higher structure groups and their classifying spaces, namely String [Ki88][ST04], Fivebrane [SSS09][SSS12], and Ninebrane structures [Sa14]. This has a simplifying feature in that tangential structures from obstruction theory [St99][Hu94] are algebraically placed in the setting of rational homotopy theory [FHT01][FHT15][FOT08][GM13][BG76]. This setting allows us to filter out the torsion in our spaces thereby enabling us to have a much better handle on some aspects of these otherwise formidable structures. However, on the flip side, a complication arises when wishing to describe the rationalizations as spaces, since localization in general give rise to topological spaces which are not always nice [Fa96][Ne95][HMR75][BK72]. Our discussion will strike a balance between the two competing aspects and our goal in this paper is to highlight those features that have transparent descriptions.
Another aim of this paper is to investigate to which extent one can make use of the more familiar Lie group structures in describing the higher ones. In the standard Whitehead tower construction [Wh52], a structure at a given level is built from the structure at the preceding level. However, as we go up in levels, the difficulty in describing the structures in an explicit manner which is amenable to (higher) geometry and to applications seems to grow considerably. Therefore, it would be desirable to explore how much of the bundles of higher connected covers can be described using the Spin group (being a Lie group) rather than having, for instance, to go through String to describe Fivebrane and through Fivebrane to describe Ninebrane structures and so on. Of course one can deal with these structures directly (see [SSS12] [FSS12] [FSS14] [FSS15] [Sa14]), but that requires considerable machinery. Here we instead take a step back and aim to explore to which extent more classical techniques can be used to probe these structures.

It turns out that the two features, namely rationalizing and utilization of Lie groups in describing the higher connected covers, go hand in hand. The purpose of this paper is to provide a straightforward such description. One of the useful results which makes this possible is that of Neisendorfer [Ne95] (see also [MM97]) which states that every finite 2-connected complex can be rationally recovered from its $n$-connected cover for any $n$. This is much stronger than saying that these spaces must have nontrivial homotopy in infinite dimensions. As explained in [Fa96] it says that this ‘infinite tail’ has all the information needed to reconstruct the ‘lower-dimensional information’. This then allows us to appropriately introduce (in Sec. 3.2 and Sec. 3.3) the notions of rational Spin-Fivebrane and Spin-Ninebrane structures as the desired structures arising from starting with Spin rather than with String and Fivebrane, respectively.

In general, we would like to start with a Lie group $G$ and then rationalize, via the rationalization or localization at $\mathbb{Q}$ functor $L_\mathbb{Q}$, as well as take connected covers simultaneously. A natural question then is whether these operations are compatible, in the sense of the existence of a diagram of the form

$$
\begin{array}{ccc}
X & \xrightarrow{\langle n \rangle} & X \langle n \rangle \\
L_\mathbb{Q} \downarrow & & \downarrow L_\mathbb{Q} \\
X_\mathbb{Q} & \xrightarrow{?} & X_\mathbb{Q} \langle n \rangle.
\end{array}
$$

One of the simplifying features of the process of rationalization is that for group-like spaces it has the effect of killing off any nonabelian structure that exists. Schematically,

Rationalization $\sim$ Homotopy abelianization.

This then gives that all connected cover groups will not only have rational models, but that these will be homotopy abelian. Corresponding statements about the classifying spaces are deduced similarly. Our main focus will be on the secondary structures arising from the groups in the Whitehead tower of the orthogonal group $O(n)$ and, in particular, we will focus on the rationalizations of these groups. Given an $O(n)\langle k \rangle$-bundle $P \to M$, the obstruction to lifting the structure group to the $k$-connected cover $O(n)\langle k \rangle$ is given by a cohomology class on $M$ obtained by pulling back the generator $\theta_{k+1} \in H^{k+1}(B(O(n)\langle k \rangle); \pi_k(O(n)))$ along the classifying map $f : M \to B(O(n)\langle k \rangle)$.

Note that for Lie groups, maps between their classifying spaces can be determined via Lie theory, with an intimate connection to rational cohomology [AM76]. In fact, homomorphisms $H^*(BG; \mathbb{Q}) \to H^*(BG'; \mathbb{Q})$ determine corresponding homomorphism with coefficients in $\mathbb{Z}_p$, the ring of integers localized at a prime $p$, and in $\mathbb{Z}/p$ the field of integers modulo $p$, except for a finite number of primes [AM76]. This indicates that rational cohomology knows quite a bit about the structure of the classifying spaces. We hope that our investigation on rational cohomology of classifying spaces of the connected covers will eventually carry some of the similar features.
From a third point of view, we are interested in considering classes in degrees 3, 7, and 11 arising from the fibers of the bundles, rather than directly from classifying spaces. These secondary classes emerge when trivializing the topological obstructions that occur in degrees 4, 8 and 12. We are interested in the variation of the structures, i.e. in the space of such structures. Given that we are considering higher structures in a way which builds on all the lower levels that precede it, we ask how the variation of that top structure depends on the lower ones all the way down to the bottom-most level, which is a Spin structure.

The rational structures we consider will be characterized by trivializations of (fractions of) the rational Pontrjagin classes $p_i$. Indeed, we can alternatively view the above structures as variants of $p_i$-structures, so that we have lifting diagrams

$$\xymatrix{ X \ar[r]^f \ar[dr]^\tau & BO\langle p_i \rangle \ar[d] \ar[r] & \text{BSO} = BO\langle w_1 \rangle, }$$

where $w_1$ is the first Stiefel-Whitney class. Note that we have the obstructions as $\frac{1}{m}p^n_i$, whose vanishing is equivalent to the vanishing of the rational Pontrjagin class $p^n_i$ itself, due to the absence of any torsion. The notion of $p_i$-structures plays an important role in quantum field theories on extended surfaces and 3-manifolds [BHMOV95][Sa04][BN14][FSV16]. Extension to Fivebrane and Ninebrane structures has been considered in [Sa14], and the corresponding twisted versions come up in [Sa13]. We will be interested also in the finite rank case as well as the indefinite signature case, where our main objects will be covers of $SO(n)$ and $SO(q, n-q)$ discussed in Sec. 2.4.

The rational cohomology of $BSO(n)$ splits into cases according to whether $n$ is even or odd

$$H^*(BSO(2n + 1); \mathbb{Q}) = \mathbb{Q}[p_1, \ldots, p_n], \quad H^*(BSO(2n); \mathbb{Q}) = \mathbb{Q}[p_1, \ldots, p_n, e]/(e^2 - p_n),$$

where $e \in H^{2n}(BSO(2n); \mathbb{Q})$ is the Euler class and $p_i \in H^{4i}(BSO(2n); \mathbb{Q})$ are the rational Pontrjagin classes. Unlike the integral versions, the rational Pontrjagin classes are topological invariants [No65][RW10], which makes them reliable under homeomorphisms. A vanishing criterion for $p^n_i$ is given in [Mo93]. It is a classic result (see [We15]) that restrictions of the classes $p_i$ to the classifying space of finite-dimensional vector bundles satisfy the vanishing relations $p_{n+k} = 0 \in H^{4n+4k}(BO(2n); \mathbb{Q})$ for $k > 0$.

The rational Pontrjagin classes have been used in [ERW15] in the context of cobordism spectra. A version of the Witten genus can be described by requiring the rational first Pontrjagin class to vanish; see e.g. [De99][CHZ11] (and references therein), where a similar definition of a rational structure is used. There, a Spin manifold $M$ is a rational $BO(8)$ manifold if and only if $p_1(M)$ is a torsion class. Furthermore, the rational Pontrjagin classes are used in classifying bundles in [KR91], where it is shown that rank $4n$ vector bundles over the $4n$-sphere $S^{4n}$ are classified by their Euler class and the rational $n$th Pontrjagin class $p^n_i$ for $n = 1, 2$. Such bundles classically arise in determining obstructions to lifting to higher connected covers (see [SSS09]). We, therefore, consider the question of the relation of the connectivity to the rank in Section 2.4.

The rational cohomology of the String group has been considered in [SSS09][BS09]. Also in specific ranks in relation to connectivity degree, $BO(2n)/n$ appear in the context of cobordism categories [ERW15], where the isomorphism $H^*(BO(2n)/n; \mathbb{Q})[-2n] \cong H^*(M\theta^n; \mathbb{Q})$ of graded vector spaces is established. Here $M\theta^n$ is the Madsen-Tillman cobordism spectrum with a tangential structure $\theta^n$, i.e. a structure on a space associated to an $n$-connected cover. For $n = 4, 8$ and 12, this corresponds in our terminology to rational String, Fivebrane, and Ninebrane structures, respectively.
We consider minimal models (see [FHT01] [FHT15] [FO10] [GM13] [BG76]) for our rational connected covers straightforwardly in Sec. 2.3. The main idea of Sullivan’s approach to rational homotopy theory is to create a functor from the category of 1-connected topological spaces to the category of differential graded commutative algebras (DGCAs) over $\mathbb{Q}$. Such a DGA is of the form $(\wedge V, d)$ where the underlying algebra is free commutative and such that there is a basis which admits an ordering so that $d(x_\alpha) \in \wedge \langle x_\beta \rangle_{\beta < \alpha}$. Furthermore, $(A, d)$ is minimal if the image of the differential $d$ is contained in the set of decomposable elements, and a minimal model is a quasi-isomorphism $\varphi : (\wedge V, d) \to (A, d)$ where $(\wedge V, d)$ is a minimal Sullivan DGA. In fact every DGA has a minimal model, and this model is unique up to isomorphism.

Then in the following sections we consider variations on rational String and Fivebrane structures. We use the word variation to mean two things at the same time: First, that we consider variations on the notion of Fivebrane and Ninebrane structures. Second, we consider variations of the actual structures (in their ‘parameter space’) and consider how these are given in terms of structures stemming from lower levels in the Whitehead tower. Theorem 17 demonstrates the degree to which the underlying Spin bundle can be used to classify lifts of the String bundles rationally. By defining these classes via their restriction on each fiber, we have many nice parallels between the integral and rational cases, as well as between those classes defined on the Spin bundle and those on the String bundle. In some sense, we find that rationally all the information for Fivebrane and Ninebrane structures is encoded in the underlying Spin bundles. Similar arguments and results hold for the Spin-Ninebrane case, except now variations of these involve both String and Fivebrane structure classes.

In Sec. 3.4 we consider automorphisms of the rational structures that we introduced. Rational automorphisms of fiber bundles are considered generally in [Sm01]. Since our higher groups are rationally abelianized, the description will be more straightforward, making use of classic results on mapping spaces to Eilenberg-MacLane spaces [Ha82] [Ha81] [Th57]. We also study the connected covers of the gauge group $G$ itself and study when a variant of String, Fivebrane, and Ninebrane lifts of $G$ are possible in relation to corresponding lifts of the structure group $G$. This turns out to impose strong constraints on both on the underlying space $X$ as well as on $G$ in a correlated manner. We make use of the results on rational homotopy of mapping spaces in [FO09], which generalize those of [Wo07].

Some of the calculations in this note are based on the second author’s PhD thesis [Wh16]. The point of view and constructions developed here naturally lead to connections to geometry, which we will leave for a separate more thorough treatment to be developed elsewhere. For describing manifolds in rational homotopy theory, one transitions from using $\mathbb{Q}$-coefficients to $\mathbb{R}$-coefficients. However, if one considers geometry then there would be important and subtle differences, as witnessed explicitly for instance in differential cohomology [GS17]. Consequently, this would lead to action functionals in physics taking values in $\mathbb{R}/\mathbb{Q}$, which would require separate treatment. This together with applications, along the lines of [Sa13] [Sa11], will be discussed elsewhere. Note also that the description of rational higher connected covers in this paper should be related to the description of their Morava K-theory in [SY17], as Morava K-theory at chromatic level zero is essentially rational cohomology. So some of the complementary torsion information not considered here is supplied in [SY17].

**Notation.** We will use the notation $O(n)$ to denote the $(n - 1)$-connected cover of the stable orthogonal group $O$. We use $BO(n + 1)$ to mean $B(O(n))$, so that for our cases of interest $BO(4) = B(O(3)) = B\text{Spin}$, $BO(8) = B(O(7)) = B\text{String}$, $BO(12) = B(O(11)) = B\text{Fivebrane}$, and $BO(16) = B(O(15)) = B\text{Ninebrane}$.
2. Rationalization of spaces and their approximations

2.1. The rational Postnikov and Whitehead towers. We start by briefly reviewing some relevant concepts in rational homotopy theory; see [He07] [FHT01] [FOT08] [GM13] [HMR75].

Definition 1. A rational space $Y$ is a space for which the homotopy groups $\pi_\ast(Y)$, or the homology groups $\tilde{H}_\ast(Y;\mathbb{Z})$, or $\tilde{H}_\ast(\Omega Y;\mathbb{Z})$ is (equivalently) a vector space over $\mathbb{Q}$, where $\Omega Y$ is the based loop space of $Y$.

Definition 2. A rationalization of a space $X$ prescribes a map $\ell_X : X \to X_\mathbb{Q}$ to a rational space $X_\mathbb{Q}$ such that $\ell_{X\ast} : \pi_\ast(X) \otimes \mathbb{Q} \to \pi_\ast(X_\mathbb{Q})$ is an isomorphism, and for every map $f : X \to Y$ where $Y$ is a rational space, there is a factorization

$$
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow \ell_X & & \downarrow h \\
X_\mathbb{Q} & & \\
\end{array}
$$

which is unique up to homotopy.

The second property in Definition 2 tells us that the space $X_\mathbb{Q}$ is unique up to homotopy. Suppose $X'_\mathbb{Q}$ is another rational space and we have a map $\ell'_X : X \to X'_\mathbb{Q}$ satisfying the second property. Then there is a homotopy equivalence $h : X_\mathbb{Q} \to X'_\mathbb{Q}$, unique up to homotopy, such that

$$
\begin{array}{ccc}
X & \xrightarrow{\ell_X} & X_\mathbb{Q} \\
\downarrow f & & \downarrow h \\
X' & \xrightarrow{\ell'_{X}} & X'_\mathbb{Q} \\
\end{array}
$$

is a homotopy commutative diagram. Note that an abelian group $G$ is said to be $\mathbb{Q}$-local if the map $G \otimes \mathbb{Z} \mathbb{Q} \to G \otimes \mathbb{Z} \mathbb{Q}$ induced by the inclusion $\mathbb{Z} \to \mathbb{Q}$ is an isomorphism. Then Definition 1 can be restated as saying that the following holds [Su74]

$$
X \text{ is a rational space } \iff \pi_n(X) \text{ is } \mathbb{Q}-\text{local } \iff \tilde{H}_n(X;\mathbb{Z}) \text{ is } \mathbb{Q}-\text{local},
$$

for $X$ nilpotent, i.e. if its fundamental group $\pi_1$ is a nilpotent group and if $\pi_1$ acts nilpotently on the higher homotopy groups. In particular, any simply connected space is trivially nilpotent. Note, however, that an extension to path connected spaces with general (not necessarily nilpotent) $\pi_1$ is possible (see [FHT15]). This allows us, for instance, to start our Whitehead tower (Example 3 below) with $\text{SO}(n)$ or $\text{BO}(n)$, as in [SS15].

Example 1 (Eilenberg-MacLane spaces). Consider the integral Eilenberg-MacLane space $K(\mathbb{Z},n)$. Then the map $\iota_{\mathbb{Q}} : K(\mathbb{Z},n) \to K(\mathbb{Q},n)$ corresponding to the generator $[\iota_{\mathbb{Q}}] \in H^n(K(\mathbb{Z},n);\mathbb{Q})$ is a rationalization of $K(\mathbb{Z},n)$. In general, an Eilenberg-MacLane space $K(\pi,n)$ can be rationalized to $K(\pi \otimes \mathbb{Q},n)$, as induced by the natural homomorphism $\pi \to \pi \otimes \mathbb{Q}$. By induction and use of the Serre spectral sequence one can show that $H^\ast(K(\mathbb{Q},2n);\mathbb{Q})$ is a $\mathbb{Q}$-polynomial algebra on one generator of degree $2n$, while $H^\ast(K(\mathbb{Q},2n+1);\mathbb{Q})$ is a $\mathbb{Q}$-exterior algebra on one generator of degree $2n+1$. Furthermore, $K(\mathbb{Z},n) \to K(\mathbb{Q},n)$ induces an isomorphism on rational cohomology. That is, there are isomorphisms (see [GM13] [Mo01])

$$
H^\ast(K(\mathbb{Z},2n);\mathbb{Q}) \cong H^\ast(K(\mathbb{Q},2n);\mathbb{Q}) \cong \mathbb{Q}[\iota],
$$

$$
H^\ast(K(\mathbb{Z},2n+1);\mathbb{Q}) \cong H^\ast(K(\mathbb{Q},2n+1);\mathbb{Q}) \cong \wedge_{\mathbb{Q}}[\iota],
$$

where $\iota \in H^n(K(\mathbb{Q},n);\mathbb{Q})$ is the fundamental cohomology class.

To construct a rationalization for a simply connected space $X$, one can use the Postnikov tower decomposition of $X$ and localize at each step of the tower. Note that one of the main properties of the rational
Similarly, one may construct the Whitehead tower over the rationalization cohomology group \[ H_\ell \]
Given that \( p \)-groups, then the homotopy pullback \( X \rightarrow X \)
where each space \( \phi \) where the map \( \rightarrow \rightarrow \)
spaces and maps \( \rightarrow \rightarrow \)
Example 2 (Postnikov tower). Recall that the Postnikov tower of \( X \) (see e.g. [Ha02]) is a sequence of spaces and maps
\[
X \longrightarrow \cdots \longrightarrow X_{(n)} \xrightarrow{\varphi_n} \cdots \xrightarrow{\varphi_2} X_{(1)} \xrightarrow{\varphi_1} X_{(0)} ,
\]
where the map \( \varphi_n \) is a fibration for every \( n \), for each space \( X_{(n)} \) one has \( \pi_i(X_{(n)}) = 0 \) for \( i > n \), and the induced map \( \varphi_n : \pi_i(X_{(n)}) \rightarrow \pi_i(X_{(n-1)}) \) is an isomorphism for \( i < n \). Now assume that we have a localization \( \ell_{(n-1)} : X_{(n-1)} \rightarrow X_{(n-1)Q} \). The principal fibration \( X_{(n)} \rightarrow X_{(n-1)} \) is the pullback of the path fibration \( PK(\pi_n(X), n+1) \rightarrow K(\pi_n(X), n+1) \) by the Postnikov invariant \( k^{n+1} \in H^{n+1}(X_{(n-1)}, \pi_n(X)) \). Now define \( X_{(n)Q} \) to be the pullback of the fibration \( PK(\pi_n(X) \otimes \mathbb{Q}, n+1) \rightarrow K(\pi_n(X) \otimes \mathbb{Q}, n+1) \) by the rationalized Postnikov invariant
\[
k^{n+1} \otimes \mathbb{Q} \in H^{n+1}(X_{(n-1)Q}, \pi_n(X) \otimes \mathbb{Q}) .
\]
This then gives the localization map \( \ell_{(n)} : X_{(n)} \rightarrow X_{(n)Q} \), completing the induction, as the base case of the induction holds because \( X \) is simply connected. Defining \( X_Q \) as the inverse limit \( X_Q := \lim \rightarrow X_{(n)Q} \), the rationalization of \( X \) is then the induced map \( \ell : X \rightarrow X_Q \).

We now consider the dual notion of the Whitehead tower [Wh52] and its rationalization.

Example 3 (Whitehead tower). The Whitehead tower is a sequence of spaces
\[
\cdots \longrightarrow X\langle n \rangle \longrightarrow X\langle n-1 \rangle \longrightarrow \cdots \longrightarrow X\langle 1 \rangle \longrightarrow X ,
\]
where each space \( X\langle n \rangle \) is \((n-1)\)-connected, and the map \( X\langle n \rangle \rightarrow X \) induces isomorphisms on the homotopy groups \( \pi_i \) for each \( i \geq n \). As with the Postnikov tower, the Whitehead tower may be constructed by induction. Given an \((n-1)\)-connected cover \( X\langle n \rangle \) of \( X \), there is a map \( w_n : X\langle n \rangle \rightarrow K(\pi_n(X), n) \) corresponding to the generator of \( H^n(X\langle n \rangle; \pi_n(X)) \). Then the space \( X\langle n+1 \rangle \) is constructed as the homotopy fiber of \( w_n \). Similarly, one may construct the Whitehead tower over the rationalization \( X_Q \) of \( X \) (see e.g. Ch. 2 in [Kr02]). By choosing \( w_n \otimes \mathbb{Q} : X\langle n \rangle \rightarrow K(\pi_n(X) \otimes \mathbb{Q}, n) \) as the classifying map for the generator of the cohomology group
\[
H^n(X\langle n \rangle \otimes \mathbb{Q}; \pi_n(X_Q)) \cong H^n(X\langle n \rangle; \pi_n(X) \otimes \mathbb{Q}) ,
\]
then the homotopy pullback \( X\langle n+1 \rangle_Q \) is the rationalization of \( X\langle n+1 \rangle \). This also follows by induction. Given that \( \ell_n : X\langle n \rangle \rightarrow X\langle n \rangle_Q \) is a localization of \( X\langle n \rangle \), we can consider the following commutative diagram
\[
\begin{array}{ccc}
X\langle n+1 \rangle & \xrightarrow{\ell_{n+1}} & PK(\pi_n(X), n) \\
\downarrow & \downarrow & \downarrow \\
X\langle n+1 \rangle_Q & \rightarrow & PK(\pi_n(X_Q), n) \\
\downarrow & \downarrow & \downarrow \\
X\langle n \rangle & \xrightarrow{\ell_n} & K(\pi_n(X), n) \\
\downarrow & \downarrow & \downarrow \\
X\langle n \rangle_Q & \rightarrow & K(\pi_n(X_Q), n) .
\end{array}
\]
The map \( \ell_{n+1} : X\langle n \rangle \rightarrow X\langle n \rangle_Q \) exists by the universal property of pullbacks and, by the commutativity of the diagram, this map is a rational homotopy equivalence.

Remark 1. In the following sections we will be concerned with the rational Whitehead tower of \( BO \). In light of this, we briefly describe one important quality of the rational Whitehead tower. The general construction of each stage of the Whitehead tower is as the homotopy fiber of a map representing a generator of cohomology. Consider a map \( f : X \rightarrow K(A, n) \) and suppose that \( f \) represents a generator of \( H^n(X; A) \). Composing
the rational homotopy groups are given as
degree $j$ $\pi^r_j(K(A, n) \to K(A \otimes \mathbb{Q}, n)$ gives a generator $f^*i \in H^n(A; \mathbb{Q})$. Then for any $r \in \mathbb{Q}$, the class $r \cdot f^*i$ is also a generator. Now by the universal property of rationalization, there is a map $f_Q : X_Q \to K(A \otimes \mathbb{Q}, n)$ as well as a map $r \cdot f_Q : X_Q \to K(A \otimes \mathbb{Q}, n)$. Denote the homotopy fibers of each of these maps as $F(f_Q)$ and $F(r f_Q)$. The key point here is to note that these spaces are homotopy equivalent. This follows from the fact the map $r : K(\mathbb{Q}, n) \to K(\mathbb{Q}, n)$ representing $r$ times the identity induces an isomorphism on the rational cohomology of rational spaces and thus is a homotopy equivalence combined with the fact that $r \cdot f^*i = f^*i \circ r$. This is in contrast to the case where we compare $\text{hofib}(f)$ and $\text{hofib}(r f)$ for some integer $r \neq \pm 1$. These are not homotopy equivalent spaces for the reason that $r$ is not a unit in $\mathbb{Z}$.

2.2. Rationalizing higher connected covers. The groups we consider will be rationally built out of spheres. Since the homotopy groups $\pi_j(S^{2m+1})$ of an odd-dimensional sphere $S^{2m+1}$ are finite except in top degree $j = 2m + 1$, the rationalization is $\ell_Q : S^{2m+1} \to K(\mathbb{Q}, 2m + 1)$ corresponding to a nontrivial class in $H^{2m+1}(S^{2m+1}, \mathbb{Q})$. Note that we have rational equivalences $S^{2m+1} \simeq \mathbb{Q} K(\mathbb{Z}, 2m + 1) \simeq \mathbb{Q} K(\mathbb{Q}, 2m + 1)$, i.e., the rational homotopy groups are given as

$$
\pi_i(S^{2n+1}) \otimes \mathbb{Q} \cong \begin{cases} 
\mathbb{Q}, & \text{if } i = 2n + 1 \\
0, & \text{otherwise}.
\end{cases}
$$

As a result, odd-dimensional spheres have the rational homotopy type of an abelian topological group, obtained by iteratively applying the classifying space functor.

The spaces we will consider are all H-spaces, and in particular H-spaces are formal. This means that the rational homotopy type of these spaces is completely determined by their cohomology ring. For a finite-dimensional Lie group $G$, its rational cohomology is the same as that of a product of odd-dimensional spheres

$$
H^*(G; \mathbb{Q}) \cong H^*(\prod S^{2i-1}; \mathbb{Q}) ,
$$

which implies that $G$ has the same rational homotopy type as that product. For our main example,

$$
\text{Spin}(2n) \simeq \mathbb{Q} S^{2n-1} \times S^3 \\
\text{Spin}(2n + 1) \simeq \mathbb{Q} S^{3} \times S^7 \times \cdots \times S^{4n-1}.
$$

We can consider the question of rationalization of higher topological groups in some generality. Suppose $G$ is a topological group having the homotopy type of a CW complex. Rationalization commutes with products only up to homotopy. This implies that the rationalization of the product structure gives a map $\mu_Q : G_Q \times G_Q \to G_Q$, which may fail to be a multiplication. However, it is a group-like H-space. The map $\ell_Q : G \to G_Q$ is a homomorphism of H-spaces, i.e. the diagram

$$
\begin{array}{ccc}
G \times G & \xrightarrow{\mu} & G \\
\ell_Q \times \ell_Q \downarrow & & \ell_Q \\
G_Q \times G_Q & \xrightarrow{\mu_Q} & G_Q
\end{array}
$$

commutes up to homotopy, and the homomorphism is compatible with homotopy associativity. When $G$ is connected, the commutator map $\mu_Q : G_Q \times G_Q \to G_Q$ is null homotopic [KSS09].

Note that the resulting rationalizations of the connected cover groups and their classifying spaces in this section end up having nice models. Explicitly, they end up being products of rational Eilenberg-MacLane spaces. Spaces are in general twisted products of Eilenberg-MacLane spaces arranged by their Postnikov decompositions. So in this case rationalization trivializes the Postnikov $k$-invariants, thereby untwisting the product of Eilenberg-MacLane spaces into a straight product. This can also be discussed on general grounds. Note that rationalization does not take a space outside the convenient category of CW complexes: If $X$ is a topological space which is a CW-complex then the rationalization $X_Q$ is also a CW-complex.
When $G$ is a connected topological group having the homotopy type of a finite CW complex, then we have that $G\mathbb{Q}$ is a homotopy commutative H-space. It is homotopy equivalent as an H-space to a product of Eilenberg-MacLane spaces with standard loop multiplication \[\text{KSS09}\]. A priori, a product of Eilenberg-MacLane spaces in general may admit many non-H-equivalent H-structures and thus the standard loop multiplication is not necessarily unique, even up to homotopy (see \[\text{Cu68}\]). However in the rational case, as we are considering here, this multiplication is unique up to homotopy \[\text{LPSS09}\].

For relatively low $k$ the connected covers $O(n)_k$ are defined as the based loop spaces of the corresponding classifying spaces in \[\text{SSS12}\] \[\text{FSS12}\] \[\text{Sa14}\]. It follows from the works of Kan and Milnor that every based loop space has the homotopy type of a topological group. In the homotopy category of connected CW complexes, there is an equivalence between loop spaces, topological groups, and associative H-spaces (see \[\text{Ka88 Ch. 4}\]).

**Proposition 3.** In the Whitehead tower of the orthogonal group, each element in the sequence of connected covering spaces \{$\text{String}(n)_\mathbb{Q}, \text{Fivebrane}(n)_\mathbb{Q}, \text{Ninebrane}(n)_\mathbb{Q}, \cdots$\} is an abelian topological group, and this group structure is unique up to rational H-equivalence.

**Proof.** (Outline) In the context of Lie groups, one can form a product on the rational homotopy groups called the Samelson product. Without defining this product, we have the following properties. From \[\text{Wo07}\], if $G$ is a (possibly infinite-dimensional) connected Lie group, then the rational Samelson product vanishes. From \[\text{LPSS09}\], for $(G, \mu)$ a connected CW homotopy-associative H-space, the following are equivalent:

1. $(G, \mu)$ has the rational H-type of an abelian topological group.
2. $(G, \mu)$ is rationally homotopy-abelian.
3. The Samelson bracket vanishes.
4. There is a rational H-equivalence \[e : G \to \prod_{j \geq 1} K(\pi_j(G) \otimes \mathbb{Q}, j)\]

where the product of Eilenberg-MacLane spaces has the standard multiplication.

So, given a Lie group $G$, its Samelson product vanishes and thus $G$ is rationally homotopy-abelian. Moreover, for the orthogonal group as well as its connected covers, these groups are rationally equivalent to products of $K(\mathbb{Q}, n)$ spaces. Considering $\mathbb{Q}$ as an abelian group, it follows that $K(\mathbb{Q}, n) \simeq B^n\mathbb{Q}$ is also an abelian group. Thus for groups involved in the Whitehead tower of $O(n)$, each space admits a rationalization by an abelian group. Moreover, for our types of groups $G$ this rational equivalence will be multiplicative and will correspond to the unique abelian multiplication coming from the standard multiplication on Eilenberg-MacLane spaces (see \[\text{LPSS09 Corollary 4.26 and 4.27}\]).

We now consider compatibility of rationalization with taking connected covers. Indeed, such a problem can be studied systematically, building on classical results. Consider localization $L_f$ at every prime, i.e. with respect to a map $f : \sqrt{p} B\mathbb{Z}/p \to \ast$ with domain the infinite bouquet. Let $E$ be defined by the homotopy pullback diagram

\[\begin{array}{ccc}
E & \longrightarrow & X(n)_\mathbb{Q} \\
\downarrow & & \downarrow \\
X & \longrightarrow & X_\mathbb{Q},
\end{array}\]

where $X$ is a simply connected finite complex with $\pi_2(X)$ finite. Then $L_fX\langle n\rangle$ has the homotopy type of $E$ \[\text{Ne95}\]. We now connect this to the Whitehead tower of the rationalized orthogonal group. Since every
level of that Whitehead tower is a rationalization [Fa96, Theorem A.1] this implies that at every level we will have a space which is at least an $H$-space. These will include all connected covers. Let us apply the above localization (2.1) to $X = \text{Spin}(n)$, which is 2-connected.

**Example 4** (Rationalization of the 3-connected cover of Spin$(n)$). Let Spin$_r$ be the homotopy fiber of the rationalization Spin $\to$ Spin$_Q$. Starting with the fiber sequence $K(Z, 2) \to \text{String}(n) = \text{Spin}(n)(7) \to \text{Spin}(n)$, we have $K(Z, 2) \otimes \mathbb{Q} \cong K(\mathbb{Q}, 2)$ as the homotopy fiber of $E \to \text{Spin}(n)$ and $K(Z, 2)_r$ as the homotopy fiber of String$(n) \to E$. The hypotheses imply that $E$ has the same rational homology as Spin$(n)$, so that $E$ is $f$-local and that $K(Z, 2)_r$ is connected. The homotopy groups of the latter are locally finite. Now the main point (see [Ne95]) is that if $Y$ is an $f$-local space, then by studying the Postnikov factorization, every map String$(n) \to Y$ has up to homotopy a unique extension to a map $E \to Y$. This identifies $L_f\text{String}(n)$ as $E$.

We now consider the rationalization of the classifying spaces of Lie groups and their higher connected covers. For classifying spaces, the Borel-Hopf theorem implies that the map $(BG)_Q \to B(G_Q)$ induced by the homomorphism $\ell_Q : G \to G_Q$ is a homotopy equivalence, and for connected $G$ we have

$$H^*(BG; \mathbb{Q}) \cong \mathbb{Q}[y_1, \cdots, y_k],$$

where each generator $y_i$ is of even degree. Note that for the classifying spaces in terms of even generators, one cannot deduce a similar relation to spheres as above, since the rational model for even-dimensional spheres is not free. It is known that the minimal model (see Sec. 2.3) of $BG$ is evenly generated and has zero differential, i.e., $BG$ is rationally a product of even-dimensional Eilenberg-MacLane spaces. The above argument also applies if we have infinitely many $y_i$'s in even degrees, as in the case for $B\text{String}$, $B\text{Fivebrane}$ and $B\text{Ninebrane}$, as long as there are only finitely many $y_i$ in each even degree. This follows from the fact that two nilpotent spaces with finite Betti numbers are rationally homotopy equivalent if and only if they have isomorphic minimal models. When $G$ is connected, the classifying space $BG$ has the rational homotopy type of a generalized Eilenberg-MacLane space (see [FO09] for another explicit description) and, in particular, it is rationally homotopy equivalent to a loop space $K\mathbb{Q}$. This implies that we can deloop as much as we desire.

Note that the behavior of the rationalization of a Lie group $G$ is intimately linked to that of its classifying space $BG$. Two compact Lie groups $G$ and $H$ are isomorphic if and only if their classifying spaces $BG$ and $BH$ are homotopy equivalent [Mo02, Os92, No95]. The equivalences at the rational level are established in [Mo02]. Since, rationally, taking the classifying functor only shifts the degree of the generators, then in this case we have that, rationally, $BG$ is a product of even-dimensional Eilenberg-MacLane spaces. Similarly in this case, taking connected covers gives the rational models for the higher connected covers of the classifying spaces. Indeed, for the case of String this can be found explicitly for instance via the Serre spectral sequence (see [SSS09, BS09]). The higher cases work similarly. Therefore, we have

**Proposition 4.** Given that the rational cohomology of $BG_Q = \mathbb{Q}[x_{2i}]$ (where $i$ can be odd or even), the rational cohomology of the connected cover $BG<n>Q = \mathbb{Q}[x_{2j}]$, where $j$ runs over the subset of values of $i$ such that $2i \geq n$. The same holds for the rational homotopy of the space.

Another way to relate $G<n>Q$ to $BG<n>_Q = BG<n+1>_Q$ is as follows. Rationalization is a weak rational equivalence $X \to L_Q(X)$, where $L_Q$ is the $Q$-localization functor. Suspension and looping preserve the rationality of the spaces involved. More precisely, for any simply connected space $X$, the loop space of its rationalization is $\Omega X_Q \cong \prod_a K(Q, m_a)$ for various values of $m_a$ [St13]. Note that in one approach to the String group, it is taken to be the loop space of its classifying space, with the latter constructed first (see [SSS12]). Indeed, for $Y = BG<n> a pointed topological space, the assignment $X \mapsto [X, \Omega BG<n>_Q]$ :=
Proposition 5. The following standard result from rational homotopy theory provides a recipe for constructing a minimal model of a fibration is given by 

\[ A \] defined to be a minimal model for \( X \), then taking the loop space leads to

\[ \text{String}_Q \simeq \Omega(B\text{String})_Q \simeq \prod K(Q, m_\alpha). \]

The values of \( m_\alpha \) can be deduced from another approach, namely starting with the Spin group, taking connected covers and then rationalizing, as we did earlier. A similar treatment for Fivebrane and Ninebrane can be established in parallel. Overall, we can arrive at the result that the rational models for \( \text{Spin}(n) \langle k \rangle_Q \) and \( \text{BSpin}(n) \langle k \rangle_Q \) are indeed given as products of rational Eilenberg-MacLane spaces.

We next consider another way of obtaining the rational homotopy type from the rational cohomology ring and vice versa.

2.3. Minimal Models. Now we present minimal models (see \([FHT01],[FHT15],[FOT08],[GM13],[BG76]\)) for our connected covers in a straightforward manner. Given a space \( X \), one can assign the complex of piecewise linear differential forms, \( A^*_PL(X) \) (see \([GM13]\) for a definition). This assignment defines a functor from the category of topological spaces to the category of CDGAs over the rationals. A minimal model for a CDGA \( (A, d) \) is given by a quasi-isomorphism \( \varphi : (\wedge V, d_V) \to (A, d_A) \) where \( \wedge V \) is freely generated and the image of \( d_V \) is contained in the set of decomposable elements of \( \wedge V \). For a space \( X \), a minimal model for \( X \) is defined to be a minimal model for \( A^*_PL(X) \).

Let \( E \xrightarrow{p} B \) be a quasi-nilpotent fibration with fiber \( F \), let \( f : B' \to B \) be a map of base spaces, and let \( E' \xrightarrow{\varphi} B' \) denote the pullback of \( p \) along \( f \). Letting \( (\wedge V, d_V) \to A^*_PL(B) \) be a minimal model for \( B \) then the relative minimal model for the fibration \( p \) is given by \( (\wedge V, d_V) \to (\wedge V \otimes \wedge W, d) \) where \( (\wedge V, d_V) \to (\wedge V \otimes \wedge W, d) \) is the relative minimal model for \( p \) as a map and \( (\wedge W, \bar{d}) \) is formed as the quotient \( (\wedge V \otimes \wedge W) / (\wedge V \otimes \wedge W) \). Let \( \phi : (\wedge V, d) \to (\wedge V', d') \) denote the relative minimal model for \( f \). The following standard result from rational homotopy theory provides a recipe for constructing a minimal model of a pullback (see \([FHT01],[FOT08]\)). The relative minimal model

\[
(\wedge V', d') \xrightarrow{\phi} (\wedge V' \otimes \wedge W, D) \xrightarrow{p} (\wedge W, D)
\]

is the relative minimal model for the pullback fibration \( p' \). The CDGA \( (\wedge V' \otimes \wedge W, D) \) is defined as \( (\wedge V', d') \otimes_\wedge (\wedge V \otimes \wedge W, D) \). Here \( D \) is defined by \( D(w) = (\phi \otimes 1)(d'w) \) where \( \phi \otimes 1 : \wedge V \otimes \wedge W \to \wedge V' \otimes \wedge W \), and \( (\wedge W, D) \) is obtained by a quotient.

Consider the rational Whitehead tower of \( BO(n) \). Recall (Example 3) that this tower can be constructed as a system of pullbacks where at each step of the tower, the space \( B(O(n)\langle 4k + 3 \rangle) \) is formed via the pullback of the pathspace fibration \( PK(Q, 4k) \to K(Q, 4k) \) along a map \( p_k : B(O(n)\langle 4k - 1 \rangle) \to K(Q, 4k) \) which can be thought of as a rationalization of the \( k \)-th Pontrjagin class.

The relative minimal model for the pathspace fibration of a space \( X \) is given by \( (\wedge V, d) \to (\wedge V \otimes \wedge sV, d) \to (\wedge sV, d) \) where an element \( sv \in \wedge sV \) has degree \( |sv| = |v| - 1 \). As the minimal model for the Eilenberg-MacLane space \( K(Q, 4k) \) is given by \( (\wedge (y_{4k}), 0) \), then it follows that the minimal model for the pathspace fibration is given by \( (\wedge (y_{4k}), 0) \to (\wedge (y_{4k}, sy_{4k}), d) \to (\wedge (sy_{4k}), d) \) where the differential \( d \) is given by \( d(y_{4k}) = 0 \) and \( d(sy_{4k}) = y_{4k} \). Then we immediately have the following.

**Proposition 5.** A relative minimal model for the fibration \( B(O(n)\langle 4p + 3 \rangle) \to B(O(n)\langle 4p - 1 \rangle) \), i.e. of the fibration \( BO(n)\langle 4p + 4 \rangle \to BO(n)\langle 4p \rangle \), is given by
Spin pulled back from $\Delta$. Nevertheless, we believe that it is interesting to explicitly present the minimal models as above.

\[ \text{Proposition 6.} \quad \text{The spaces and thus rationally trivial, we can state a sharper result.} \]

\[ \text{Example 6.} \]

In the case of the fibration $\text{BFivebrane}(n) \to \text{BString}(n)$, it follows that for $n$ odd the minimal model is

\[ (\wedge(x_{2p}, x_{2p+4}, \ldots, x_{4k}, \chi_{2k}), 0) \longrightarrow (\wedge(x_{2p}, \ldots, x_{4k}, \chi_{2k}, s_{4p}), d) \longrightarrow (\wedge(s_{4p}), 0), \]

where $d(s_{4p}) = x_{4p}$ and 0 otherwise.

(b) For $n = 2k + 1$:

\[ (\wedge(x_{2p}, x_{2p+4}, \ldots, x_{4k}), 0) \longrightarrow (\wedge(x_{2p}, \ldots, x_{4k}, s_{4p}), d) \longrightarrow (\wedge(s_{4p}), 0), \]

where $d(s_{4p}) = x_{4p}$ and 0 otherwise.

Note that the element $\chi_{2k}$ corresponds to the Euler class for even $n$. We now consider explicitly the cases $\text{BFivebrane}(n) := BO(n)\langle 9 \rangle$ and $\text{BNinebrane}(n) := BO(n)\langle 13 \rangle$.

\[ \text{Example 5.} \]

(i) In the case of the fibration $\text{BFivebrane}(n) \to \text{BString}(n)$, it follows that for $n$ odd the minimal model is

\[ (\wedge(x_8, x_{12}, \ldots, x_{4k}), 0) \longrightarrow (\wedge(x_8, \ldots, x_{4k}, s_{8}), d) \longrightarrow (\wedge(s_{8}), 0), \]

where $x_8$ is the element corresponding to the second Pontrjagin class.

(ii) In the case of the fibration $\text{BNinebrane}(n) \to \text{BFivebrane}(n)$ and $n$ odd, the minimal model is

\[ (\wedge(x_{12}, \ldots, x_{4n+4}), 0) \longrightarrow (\wedge(x_{12}, \ldots, x_{4n+4}, s_{12}), d) \longrightarrow (\wedge(s_{12}), 0), \]

where $x_{12}$ is the element corresponding to the third Pontrjagin class. These can be modified appropriately by adding the Euler class in the case when $n$ is even.

Note that, as was mentioned in Sec. 2.2, all the spaces we consider are $H$-spaces and thus formal. Nevertheless, we believe that it is interesting to explicitly present the minimal models as above.

2.4. Rank vs. connectivity degree. In this section we will highlight how the rank $n$ of the Spin group $\text{Spin}(n)$ will have an effect on the corresponding $k$-connected cover. We start with identifying the minimal rank so that the resulting rationalizations are not trivial, after which we consider the indefinite case $\text{Spin}(p, q)$.

\[ \text{Example 6 (The unstable case: String}(3)) \]

The case $n = 3$ is special. From the point of view of classifying spaces, the generator $Q_1 = \frac{1}{3}p_1$ in $H^4(\text{BSpin}(3); \mathbb{Z})$ is further divisible by 2, or the first Pontrjagin class pulled back from $\text{BSO}(3)$ via the covering map $\text{Spin}(3) \to \text{O}(3)$ is divisible by 4. This has interesting consequences that we will not pursue here (see [Re11, Sa10]). From the rational point of view, however, the story is different. Consider the identification $\text{Spin}(3) \cong S^3$. Now forming $\text{String}(3)$ is equivalent to forming the 3-connected cover $S^3\langle 4 \rangle$ of the 3-sphere. This latter space is known to be torsion. This is essentially due to Serre’s result that $\pi_j(S^3)$ is finite for $j > 3$. Indeed forming the fibration $\text{String}(3) \to \text{Spin}(3) \to K(\mathbb{Z}, 3)$ and rationalizing, we consider the fibration $\text{Spin}(3) \to \text{Spin}(3) \to \text{Spin}(3)\mathbb{Q}$, where the leftmost term is the homotopy fiber to be determined. This is homotopy equivalent to the fibration $S^3_{\text{un}} \to S^3 \to S^3_{\text{t}}$, where $S^3_{\text{t}} \cong K(\mathbb{Q}, 3) \cong M(\mathbb{Q}, 3)$ and the homotopy fiber $S^3_{\text{t}} \cong M(\mathbb{Q}/\mathbb{Z}, 2)$ is the Moore space for the quotient $\mathbb{Q}/\mathbb{Z}$.

In order to generalize to higher connected covers, we note that in the case of $n = 3$, we have $\dim(\text{Spin}(n)) = 3$, and the generator of $\pi_3(\text{Spin}(3))$ corresponds to the fundamental class in $H^3(\text{Spin}(3); \mathbb{Z})$. In the general case the dimension of $\text{Spin}(n)$ is $d = \frac{1}{2}n(n - 1)$. Now, while it is true that $\text{Spin}(n)\langle \frac{1}{2}n(n - 1) \rangle$ are torsion spaces and thus rationally trivial, we can state a sharper result.

\[ \text{Proposition 6.} \quad \text{The} (k-1)\text{-connected cover of rank} n \geq 2, \text{Spin}(n)\langle k \rangle_{\mathbb{Q}}, \text{is homotopy trivial for} k \geq 4 \left\lfloor \frac{n - 1}{2} \right\rfloor. \]
This rationalization is trivial, i.e. the resulting spaces are torsion spaces, when pure torsion.

\[ \text{classifying spaces, } B\rho \]

Fivebrane and Ninebrane not immediately possible. In \[\text{indfinite case}\] where the various torsion groups arising notoriously in the indefinite case made the extension to Fivebrane and Ninebrane \[Q\text{-bundle}\] such that \[\rho \text{ is a torsion space for } n\] and, upon killing this homotopy class in the Whitehead tower, the resulting space is pure torsion.

Thus, for example, we have that Fivebrane(\(n\)) := Spin(\(n\))(8) is a torsion space for \(n \leq 6\), and Ninebrane(\(n\)) := Spin(\(n\))(12) is a torsion space for \(n \leq 8\).

\textbf{The indefinite case} Spin(\(p,q\))(\(k\)). Note that we can consider rationalization of higher structures in the indefinite signature, i.e. by taking connected covers of the semi-orthogonal \(SO(p, q)\), prominent in semi-Riemannian geometry. For degree 3, i.e. for String(\(p,q\)), these are characterized in [SSL2]. The homotopy groups encountered there are complicated, but upon rationalizing the problem becomes much more tractable: For \(p, q < 3\) then the problem is trivial. If we have \(p = q = 3\) then we have two copies of the trivialization of the 3-connected cover of \(S^3\), which is pure torsion (as in Example 6). For \(p = q = 4\), we have four copies of \(S^3(4)\). So far the rationalization of all these cases is trivial. Once we reach \(p, q \geq 5\) then we have two copies of the nontrivial problem, i.e., a rationalization of String(\(p\)) and of String(\(q\)). The cases when \(p \neq q\) can be dealt with similarly.

Given the discussions in previous sections, the descriptions of the higher connected covers Fivebrane(\(p,q\)) and Ninebrane(\(p,q\)) rationally will follow analogously. Note that this is in stark contrast with the calculations in [SSL2] where the various torsion groups arising notoriously in the indefinite case made the extension to Fivebrane and Ninebrane not immediately possible.

**Proposition 7.** Let Spin(\(p,q\))(\(k\)) denote the \((k - 1)\)-connected cover of the indefinite Spin group Spin(\(p,q\)).

(i) The rationalization takes the form

\[ \text{Spin}(p,q)(k)_Q \approx \text{Spin}(p)(k)_Q \times \text{Spin}(q)(k)_Q \quad \text{if } k < 4 \cdot \frac{\min(p,q)-1}{2}. \]

(ii) This rationalization is trivial, i.e. the resulting spaces are torsion spaces, when

- \(p = q\) such that \(k \geq 4 \cdot \frac{p-1}{2} = 4 \cdot \frac{q-1}{2}\), or
- \(p \neq q\) such that \(k \geq 4(p-1), k \geq [q-1]\).

Intermediate cases can arise. For example, for Fivebrane(7,\(q\)) the first factor Fivebrane(7) is a torsion space, while the second factor Fivebrane(\(q\)) has a nontrivial rationalization for \(q > 7\).

3. **Higher tangential structures**

3.1. **Rational Structures.** Let \(G\) be a simply connected topological group. For a principal \(G\)-bundle \(P \to M\) and a homomorphism \(\rho : H \to G\) of topological groups, one says that the structure group of \(P\) lifts from \(G\) to \(H\) if there is a principal \(H\)-bundle \(Q \to M\) and a bundle isomorphism \(Q \times \rho G \cong P\) over \(M\), and any principal \(H\)-bundle satisfying this property is an \(H\)-structure for \(P\). Two \(H\)-structures are isomorphic if there is a bundle isomorphism between them. From a homotopy theoretic perspective, we can associate to any \(G\)-bundle \(P \to M\) a classifying map \(f : M \to BG\). The homomorphism \(\rho : H \to G\) induces a map of classifying spaces, \(BP : BH \to BG\) and the associated \(G\)-bundle, \(EH \times \rho G \to BH\), is classified by the map
Thus a lifting of the classifying map along \(B\rho\)

\[
\begin{array}{ccc}
M & \xrightarrow{f} & BH \\
\downarrow{\tilde{f}} & & \downarrow{B\rho} \\
BG & \xrightarrow{\tilde{f}} & BG.
\end{array}
\]

corresponds to a lifting of the structure group from \(G\) to \(H\) as \((\tilde{f}^*EH) \times_{\rho} G \cong \tilde{f}^*B\rho\times EG \cong f^*EG\). In fact given a principal \(G\)-bundle \(P \to M\) and fixing a choice of classifying map, then there is a one-to-one correspondence between homotopy classes of lifts of the classifying map along \(B\rho\) and isomorphism classes of principal \(H\)-bundles which represent lifts of the structure group from \(G\) to \(H\). We will take the homotopy theoretic perspective in understanding lifts of the structure group and use the following definition.

**Definition 8.** Let \(P \to M\) be a principal \(G\)-bundle.

1. An \(H\) structure on \(P\) is a lift of the classifying map from \(BG\) to \(BH\).
2. Two \(H\) structures \(\tilde{f}, \tilde{f}'\) are isomorphic if there exists a homotopy \(H : [0,1] \times M \to BH\) such that
   \[
   H(0,x) = \tilde{f}(x), \quad H(1,x) = \tilde{f}'(x), \quad \text{and} \quad B\rho \circ H(t,x) = f(x), \quad \forall t \in [0,1].
   \]

In [Re11], Redden studies the general case for liftings of the structure group where \(BH\) is the homotopy fiber of a map \(\lambda : BG \to K(A, k)\) for an abelian group \(A\) and such that the group \(G\) is \((k-2)\)-connected. For the purposes of this paper, we focus on topological groups arising in the Whitehead tower for \(O(n)\) and thus the cases where \(G = O(n)/\langle k-1 \rangle\) and \(H = O(n)/\langle k \rangle\). We further remark that unless otherwise stated, we assume that \(O(n)/\langle k-1 \rangle\) is in the stable range for \(n\) and will thus drop the index \((n)\) from here on out. Exploiting the connectivity of \(O(k-1)\) we have \(H^k(BO(k); \pi_{k-1}(O)) \cong \pi_{k-1}(O)\). For example, when \(k = 4\) we have \(BO(4) = BSpin\) and \(H^4(BSpin; \pi_0(O)) \cong Z\). Combining this isomorphism with Brown’s representability theorem, the generator \(\theta_k \in \pi_{k-1}(O)\) corresponds to a map \(\theta_k : BO(k) \to K(\pi_{k-1}(O), k)\). For a principal \(O(k-1)\)-bundle, we denote \(\theta_k(P) := f^*\theta_k\) and this class represents the obstruction for \(P\) to admit an \(O(k)\)-structure.

Using the loop space functor, there is a morphism \([X, K(A, k)] \to [\Omega X, \Omega K(A, k)]\) which corresponds to a morphism \(H^*(X; A) \to H^{*-1}(\Omega X; A)\). Setting \(X = BG\) and identifying \(\Omega BG \simeq G\), we obtain the transgression map \(\tau : H^*(BG; A) \to H^{*-1}(G; A)\) for any group \(G\). In fact, if the group \(G\) is \((k-2)\)-connected, then \(\tau\) is the right inverse for \(d_k\), i.e. \(d_k(\tau) = \text{Id}\), where \(d_k\) is the cohomological transgression arising from the \(k\)th page of the Serre spectral sequence of a fibration. Specializing to our case, we combine several results from Section 2 of [Re11] into the following.

**Proposition 9.** Let \(P \to M\) be an \(O(k-1)\)-bundle. Then

1. \(P\) admits an \(O(k)\)-structure if and only if \(f^*\theta_k = 0\).
2. There is a one-to-one correspondence between homotopy classes of \(O(k)\)-structures and cohomology classes \(\gamma \in H^{k-1}(P; \pi_{k-1}(O))\) such that \(i^*\gamma = \tau\theta_k(P)\).
3. The set of \(O(k)\)-structures up to homotopy is an \(H^{k-1}(M; \pi_{k-1}(O))\)-torsor.

We provide a sketch of the proof here. A full and much more detailed proof of this proposition can be found in [Re11]. We note that the first statement follows from the fact that \(BO(k+1)\) can be realized as the homotopy fiber of \(\theta_k : BO(k) \to K(\pi_{k-1}(O), k)\) and thus a lift of the classifying map \(f\) exists if and only if \(\theta_k \circ f \simeq *\). The second statement requires somewhat more detail. However we note that the map from the homotopy classes of \(O(k)\)-structures to cohomology on the total space \(P\) is given by using the contractibility of \(BO(k)\). A lift of the classifying map \(f\) to \(BO(k+1)\) induces a map on \(P\) to a fiber of \(B\rho\times EO(k)\), which by construction has the homotopy type of \(K(\pi_{k-1}(O), k-1)\), and thus defines a cohomology class in
$H^{k-1}(P; \pi_{k-1}(O))$. For the third statement, we can consider the Serre spectral sequence corresponding to the principal bundle $P \to M$. Utilizing the connectivity of the fiber, there is an exact sequence

$$0 \longrightarrow H^{k-1}(M; \pi_{k-1}(O)) \xrightarrow{\pi^*} H^{k-1}(P; \pi_{k-1}(O)) \xrightarrow{\iota_*^P} H^{k-1}(P_{x}; \pi_{k-1}(O)) \xrightarrow{d_k} H^k(M; \pi_{k-1}(O)),$$

where $\iota_*^x$ denotes the pullback along the inclusion of the fiber over $x$ and $d_k$ is the differential arising from the $k$th page of the Serre spectral sequence.

The result of this proposition is that one can classify $O\langle k\rangle$-structures by certain cohomology classes in the total space. This leads us to the following definition.

**Definition 10.** For an $O\langle k-1\rangle$-bundle $P \to M$, an $O\langle k\rangle$ class is a cohomology class $\gamma \in H^{k-1}(P; \pi_{k-1}(O))$ such that $\iota_*^x \gamma = \pi \theta_k(P)$ for each fiber inclusion $\iota_x : O\langle k-1\rangle \to P$.

Considering the process of rationalization and our discussion surrounding the rational Whitehead tower in Sec. 2.1, we can construct a nice parallel to this story of $O\langle k\rangle$ the notation of $O$. The period of the real Bott periodicity, the two homotopy groups of $O$, the rationalization of $\rho$, $\iota$ Definition 10.

For an $O\langle k-1\rangle$-bundle $P \to M$, an $O\langle k\rangle$-class is a cohomology class $\gamma \in H^{k-1}(P; \pi_{k-1}(O))$ such that $\iota_*^x \gamma = \pi \theta_k(P)$ for each fiber inclusion $\iota_x : O\langle k-1\rangle \to P$.

Considering the process of rationalization and our discussion surrounding the rational Whitehead tower in Sec. 2.1, we can construct a nice parallel to this story of $O\langle k\rangle$-structures by considering the rational Whitehead tower over $BO$. Given a homomorphism of groups $\rho : H \to G$, let $\rho_Q : H_Q \to G_Q$ represent the rationalization of $\rho$. This in turn induces a morphism of classifying spaces $B\rho_Q : BH_Q \to BG_Q$. Note that, as we have seen in Sec. 2.2 we can think about $BG_Q$ equally via either delooping of $H$-spaces or via classifying spaces of groups. On the other hand, if we have a principal $G$-bundle, then the composition of the classifying map $f : M \to BG$ with the rationalization of $BG$, $\ell_{BG} : BG \to BG_Q$, gives a map $f_Q : M \to BG_Q$. Note that as $B(G_Q) \simeq (BG)_Q$ then, in the context of classifying spaces, there is no ambiguity in using the notation $BG_Q$. In order to pursue the analogy with $G$-structures as above, we begin with the following definition.

**Definition 11.** Given a principal $G$-bundle $P \to M$, a rational $H$-structure on $P$ is given by a lift of the classifying map $f_Q : M \to BG_Q$ along the map $B\rho_Q : BH_Q \to BG_Q$.

For our purposes, we specialize this to the case of $O\langle k\rangle$-structures.

**Example 7** (Rational Whitehead tower of $O$). Consider the rational Whitehead tower corresponding to the classifying space $BO$. As the rationalization induces an isomorphism on homotopy groups tensored with $\mathbb{Q}$ and, since the only non-torsion homotopy groups $\pi_i(O)$ occur when $i = 4k - 1$, the rational Whitehead tower looks as follows

$$\cdots \to K(\mathbb{Q}, 11) \longrightarrow BO\langle 16 \rangle\mathbb{Q} = B\text{Ninebrane}_\mathbb{Q} \longrightarrow K(\mathbb{Q}, 7) \longrightarrow BO\langle 12 \rangle\mathbb{Q} = B\text{Fivebrane}_\mathbb{Q} \longrightarrow K(\mathbb{Q}, 3) \longrightarrow BO\langle 8 \rangle\mathbb{Q} = B\text{String}_\mathbb{Q} \longrightarrow K(\mathbb{Q}, 4) \longrightarrow BO\langle 4 \rangle\mathbb{Q} = B\text{Spin}_\mathbb{Q} \longrightarrow K(\mathbb{Q}, 1)$$

The first two homotopy groups of $O$ are torsion, so that $BO\langle 4 \rangle \simeq BSO\langle 4 \rangle \simeq B\text{Spin}_\mathbb{Q}$. Similarly, in the next period of the real Bott periodicity, the two homotopy groups of $O$ in degrees 9 and 10 are torsion, so that (in the notation of [Sa14], see also Sec. 3.3) $B2\text{Orient}_\mathbb{Q} \simeq B2\text{Spin}_\mathbb{Q} \simeq B\text{Ninebrane}_\mathbb{Q}$. Note that the obstructions are given a priori by fractions of the indicated Pontrjagin classes. However, since we are working rationally, these are equivalent to the bare classes.

Once we rationalize, our structures connect to classical constructions.
Example 8. (i) (Rational String structures). Let $G$ be a compact Lie group and $H$ a closed subgroup. Then
the coset space $G/H$ has vanishing $p_1^Q$ provided the Killing form of $\mathfrak{g} = \text{Lie}(G)$ restricts to a multiple of the
Killing form of $\mathfrak{h} = \text{Lie}(H)$ [Ba81]. Consequently, the same holds if the subgroup $H$ is simple [Ba81, Si82].
(ii) (Rational Fivebrane structures). Manifolds admitting differentiable action of the groups $G = SU(n)$, $SO(n)$, or $Sp(n)$ with vanishing $p_1^Q$ and $p_2^Q$ are studied in [HH67, Gr74].
(iii) (Rational Ninebrane structures). In fact, in [Si82] Prop. 3.2 a criterion for constructing quotients $G/H$
with $p_1^Q = p_2^Q = p_3^Q$ is given in terms of the positive roots $\{\beta_i\}_{i=1}^r$ of $H$. This is the requirement that the sum
$\sum_{i=1}^r \beta_i^{2m}$ is contained in the ideal $I$ of the ring $H^*(BH; \mathbb{Q})$ generated by $q^*(H^*(BG; \mathbb{Q}))$ for $1 \leq m \leq 3$.
(iv) (Rational Ninebrane structures). Requiring $p_1^Q = p_2^Q = p_3^Q = 0$ for manifolds of dimension at most
twelve is equivalent to these being rationally parallelizable. This happens for $G/H$ with $H$ locally isomorphic
to $SU(2)$ (see [Si82, Cor 3.3]).

3.2. Variations on rational Fivebrane classes. We start by discussing in detail the $k = 8$ case, i.e. when
we have a principal String-bundle and wish to investigate when it admits a rational Fivebrane structure. As
the space String is 6-connected with $\pi_7(\text{String}) \cong \pi_7(O) \cong \mathbb{Z}$, it follows from the Hurewicz and Universal
Coefficients Theorem that $H^7(\text{String}; \mathbb{Q}) \cong \mathbb{Q}$. Tracing what it means for a manifold $M$ to have a Fivebrane
structure, we make the following definitions.

Definition 12. A rational Fivebrane structure is a lift of the String-principal bundle $\pi_{\text{String}} : P \to M$ to the
homotopy fiber $\text{hofib}(\frac{1}{6}p_2^Q)$ of the rationalized classifying map $f : M \to \text{BString}_Q$.

Note here that we have chosen to study the homotopy fiber of a representative of $\frac{1}{6}p_2^Q$. As above (see
Example 7), we could have chosen to study the homotopy fiber of $p_2^Q$ or even $rp_2^Q$ for any $r \in \mathbb{Q}$, as the
resulting classifying spaces are all homotopy equivalent. The only discrepancy here will be that the rational
Fivebrane structures will differ by an homotopy equivalence. Thus, up to isomorphism, these structures are
the same.

We now refer to the discussion just before Prop. 9. Setting $a_7 \in H^7(\text{String}; \mathbb{Q})$ to be the generator given
by $a_7 := \tau(\frac{1}{6}p_2^Q)$, we make the following definition.

Definition 13. A rational Fivebrane structure class is a cohomology class $F \in H^7(P; \mathbb{Q})$ such that $i^*F = a_7 \in H^7(\text{String}; \mathbb{Q})$ for each fiber inclusion $i_x : \text{String} \to P$.

As with the integral case [SSS09], it follows that these rational Fivebrane structure classes form a torsor for
$H^7(M; \mathbb{Q})$. Furthermore, the case of finite rank can be treated similarly, taking into account the discussions
in Sec. 2.4.

At this stage, our goal is to describe higher structures (beyond Spin) using Spin structures to the extent
of which it is possible. We will do this here for Fivebrane and in the next section for Ninebrane structures.
Given a principal String-bundle $\pi_{\text{String}} : P \to M$, there is an underlying principal Spin-bundle $\pi_{\text{Spin}} : Q \to M$
which fits into the following commutative diagram

\[
\begin{array}{ccc}
\text{String} & \longrightarrow & P \\
\mu_0 & \downarrow & \pi_{\text{String}} \\
\text{Spin} & \longrightarrow & M \\
\mu & \downarrow & \pi_{\text{Spin}} \\
& Q & \mu_0
\end{array}
\]

where the homomorphism $\mu_0 : \text{String} \to \text{Spin}$ has fiber a $K(\mathbb{Z}, 2)$ and the bundle map $\mu$ is $\mu_0$ equivariant.
For the homomorphism $\mu_0$, we have the following useful fact when considering rational cohomology.

Lemma 14. The map $\mu_0 : \text{String} \to \text{Spin}$ induces an isomorphism $\mu_0^* : H^7(\text{Spin}; \mathbb{Q}) \xrightarrow{\cong} H^7(\text{String}; \mathbb{Q})$. 

15
We have defined rational Fivebrane classes solely as any class in $H^7(P; \mathbb{Q})$ which restricts to a certain generator in $H^7(\text{String}; \mathbb{Q})$. We make two notes regarding this. The first is that the transgression map is invariant under rationalization. Thus if we have a generator $\frac{1}{7}p_2 \in H^8(B\text{String}; \mathbb{Z})$, then $(\frac{1}{7}p_2)^\mathbb{Q}$ is a generator for $H^8(B\text{String}; \mathbb{Q})$. More importantly, we have $\tau((\frac{1}{7}p_2)^\mathbb{Q}) = (\tau(\frac{1}{7}p_2))^\mathbb{Q}$. The consequence of this is the following.

**Lemma 15.** The rationalization of any Fivebrane class is a rational Fivebrane class.

**Proof.** Every Fivebrane class $F \in H^7(P; \mathbb{Z})$ satisfies $\iota^*_x F = \tau(\frac{1}{7}p_2)$. Then, by naturality of rationalization and what we noted above, the rational class $F_\mathbb{Q}$ satisfies

$$
\iota^*_x F_\mathbb{Q} = (\iota^*_x F)_\mathbb{Q} = (\tau(\frac{1}{7}p_2))_\mathbb{Q} = a_7.
$$

Hence $F_\mathbb{Q}$ is a rational Fivebrane class.

Thus for any ordinary Fivebrane class, there is a corresponding rational Fivebrane class. The second thing we note is that with the isomorphism from Lemma 14 we can define a generator of $H^7(\text{Spin}; \mathbb{Q})$ as $(\rho^*)^{-1}(\tau(\frac{1}{7}p_2))$. For simplicity we will denote this class as $\tilde{a}_7$. We will also set $a_3 := \tau((\frac{1}{7}p_1)^\mathbb{Q}) \in H^3(\text{Spin}; \mathbb{Q})$. Consequently, by considering the underlying Spin bundle for our String bundle, we can define classes here similar to how Fivebrane classes are defined cohomologically.

To that end, let $\pi_{\text{Spin}} : Q \rightarrow M$ denote the underlying Spin bundle.

**Definition 16.** A rational Spin-Fivebrane class is a cohomology class $F_\mathbb{Q}$ in $H^7(Q; \mathbb{Q})$ such that $\iota^*_x F_\mathbb{Q} = \tilde{a}_7 \in H^7(\text{Spin}; \mathbb{Q})$ for each $x \in M$.

The main question we pursue now is how the two definitions, Def. 13 and Def. 16, are related. It is not too difficult to show that every rational Spin-Fivebrane class gets mapped by $\mu^*$ to a rational Fivebrane class; however we can say more, still for String bundles.

**Theorem 17.** Let $\pi_{\text{String}} : P \rightarrow M$ be a principal String-bundle and let $\pi_{\text{Spin}} : Q \rightarrow M$ be its underlying principal Spin-bundle. (i) For every rational Spin-Fivebrane class $F \in H^7(Q; \mathbb{Q})$, the pullback $\rho^* F$ is a rational Fivebrane class.

(ii) For any rational Fivebrane class $F \in H^7(P; \mathbb{Q})$ there is a Spin-Fivebrane class $\tilde{F} \in H^7(Q; \mathbb{Q})$ such that $\mu^* \tilde{F} = F$.

(iii) Two classes $F, F' \in H^7(Q; \mathbb{Q})$ will give the same rational Fivebrane class if $F - F' = S \cdot \tau^* \phi_4$ where $S \in H^3(Q; \mathbb{Q})$ is the String structure class and $\phi_4 \in H^4(M; \mathbb{Q})$ is a rational cohomology class.

**Proof.** The main ingredient that will be used in the proof is the corresponding Serre spectral sequences for the bundles $Q$ and $P$ along with the spectral sequences for the universal bundles over the classifying spaces $B\text{Spin}$ and $B\text{String}$. Let $f_{\text{Spin}}$ and $f_{\text{String}}$ be the classifying map of $Q$ and $P$ respectively. The second page of the spectral sequence for $Q$ is as follows.
As the spectral sequence converges to the cohomology of the total space and as are coefficients are \( \mathbb{Q} \), it follows that we have a non-canonical splitting

\[
H^7(Q; \mathbb{Q}) \cong E_{\infty}^{7,0} \oplus E_{\infty}^{4,3} \oplus E_{\infty}^{0,7}.
\]

Thus we want to calculate each of these terms. On \( E_{\infty}^{7,0} \), we have that the differentials \( d_r \) are all zero since \( E_{r}^{p,q} = 0 \) for \( q < 0 \). Thus the only differential of interest is \( d_4 : E_4^{3,3} \to E_4^{7,0} \). Let us determine how the differential acts on generators of \( E_4^{3,3} \). Using that \( E_4^{3,3} \cong E_2^{3,3} \cong \mathbb{Q}[a_3] \otimes H^3(M) \), then a typical generator is of the form \( a_3 u_3 \) where \( u_3 \in H^3(M; \mathbb{Q}) \). We also know that \( d_4(a_3) = \frac{1}{2} p_1 \) where \( p_1 \) is the first Pontrjagin class of \( M \), and since \( M \) admits a String structure, then \( p_1 = 0 \). Thus, since \( d_r \) are derivations, \( d_4(a_3 u_3) = d(a_3) u_3 + a_3 d(u_3) = 0 \) for any generator of \( E_4^{3,3} \) and thus \( E_{\infty}^{7,0} = H^7(M; \mathbb{Q}) \).

For \( E_{\infty}^{0,7} \), the only relevant differentials are \( d_3 : E_3^{0,7} \to E_3^{5,3} \) and \( d_8 : E_8^{0,7} \to E_8^{8,0} \). Since \( d_r \) is zero for \( r \leq 4 \) and \( 6 \leq r \leq 8 \), then it follows that \( E_{\infty}^{0,7} = \mathbb{Q}[a_7] \). To see what \( d_5 \) and \( d_8 \) map \( \mathbb{R}[a_7] \) to, we will use the spectral sequence for the universal bundle \( \text{Spin}(n) \to E\text{Spin} \to B\text{Spin} \) along with naturality of the bundle map coming from the classifying map \( f : M \to B\text{Spin} \). Let \( F_{r}^{p,q} \) represent the spectral sequence for the universal bundle. Then the map \( f : M \to B\text{Spin} \) induces maps \( f^* : F_{r}^{p,q} \to F_{r}^{p,q} \) such that \( f^* \) is the identity when \( p = 0 \). Thus \( d_5(a_7) = d_5(f^* a_7) = f^* d_5(a_7) = 0 \) since \( H^5(B\text{Spin}; \mathbb{Q}) = 0 \) which means \( E_{\infty}^{5,3} = 0 \). By the same reasoning, since \( d_8 \) maps \( a_7 \) to the generator of \( H^8(B\text{Spin}; \mathbb{Q}) \) then for \( Q \), \( d_8(a_7) = \frac{1}{2} p_2 \) where \( p_2 \) is the second Pontrjagin class. Since \( Q \) has a Fivebrane structure, then \( d_8(a_7) = 0 \) and thus \( E_{\infty}^{0,7} = E_2^{0,7} = \mathbb{R}[a_7] \).

It follows that

\[
H^7(Q; \mathbb{Q}) \cong \mathbb{Q}[a_7] \oplus E_{\infty}^{4,3} \oplus H^7(M; \mathbb{Q}).
\]

Through a similar argument, we find that \( H^7(P; \mathbb{Q}) \cong \mathbb{Q}[a_7] \oplus H^7(M; \mathbb{Q}) \) where we now have \( E_{\infty}^{4,3} = 0 \) since \( H^3(\text{String}; \mathbb{Q}) = 0 \). The bundle morphism \( \mu : P \to Q \) induces a homomorphism \( \mu^* : H^7(Q; \mathbb{Q}) \to H^7(P; \mathbb{Q}) \) and thus a homomorphism between each page of the spectral sequences. It follows that \( \mu^* \) is surjective, and that \( \text{Ker}(\mu^*) = E_{\infty}^{4,3} \). To finish the proof, it only remains for us to show that \( E_{\infty}^{4,3} = \mathbb{Q}[a_3] \otimes H^4(M; \mathbb{Q}) \). Indeed, the only nontrivial differential is \( d_4 : E_4^{4,3} \to E_4^{8,0} \) and since we have already shown that \( d_4(a_3) = 0 \) then it follows that \( d_4 \) is also trivial.

\[\Box\]

Remark 2. (i) Theorem 13 demonstrates the degree to which the underlying Spin bundle can be used to classify lifts of the String bundles rationally. The difference between the integral and rational case is torsion and the Bockstein sequence corresponding to the short exact sequence \( 1 \to \mathbb{Z} \to \mathbb{Q} \to \mathbb{Q}/\mathbb{Z} \to 1 \) prescribes to what degree that they differ. Thus two Fivebrane structures are identified rationally if their difference corresponds to a torsion class in \( H^7(M; \mathbb{Z}) \).

(ii) Furthermore, gives us a similar understanding of what happens when going from Spin-Fivebrane to Fivebrane classes rationally. Part (i) tells us that every rational Spin-Fivebrane class gives rise
to a rational Fivebrane class. Part (iii) identifies when any two rational Spin-Fivebrane classes correspond to the same rational Fivebrane class.

This says that rationally all the information on Fivebrane structures is essentially encoded in the underlying Spin bundles. In fact, it follows immediately that we have

**Corollary 18.** If $H^4(M; \mathbb{Z})$ is torsion, then the set of rational Fivebrane classes and rational Spin-Fivebrane classes are in bijective correspondence.

Settings where this occurs include the following.

**Example 9.** (i) The Witten manifolds $M_{k,\ell}$, which are $S^1$ bundles over the product of complex projective spaces $CP^2 \times CP^1$, are classified in [KSS88] according to two integers $k$ and $\ell$. They have $H^4(M_{k,\ell}; \mathbb{Z}) = \mathbb{Z}/\ell^2$.

(ii) Generalized Witten manifolds $N_{k\ell}$ are defined as the total spaces of fiber bundles with fiber the lens space $L_k(\ell_2, \ell_2)$ and structure group $S^1$. They have $H^4(N_{k\ell}; \mathbb{Z}) \cong \mathbb{Z}[\ell_1, \ell_2]$ [Es05].

(iii) Quaternionic line bundles $E$ over closed Spin manifolds of dimension $4k - 1$ with $c_2(E) \in H^4(M; \mathbb{Z})$ being torsion are considered in [CG13] via generalizations of the Kreck-Stolz invariants.

The above structures are also somewhat related to $p_1$-structures, as defined (and highlighted) in [Sa14, Def. 6.1]. In the absence of a rational String structure or, more precisely, if the obstruction $p_1^Q$ for rational String structures does not vanish, then the concept of a rational Spin-Fivebrane structure is equivalent to a rational $p_2$-structure. A $p_2$-structure is a lift of $BO$ to $BO\langle p_2 \rangle$ and a rational $p_2$-structure, i.e., a $p_2^Q$-structure, is a lift of the corresponding rationalizations.

### 3.3. Variations on rational Ninebrane classes

We now extend the results from the last section to the next higher connected cover of the orthogonal group $O$. Following [Sa14], let 2Spin and Ninebrane denote the groups $O(11)$ and $O(15)$ respectively. Notice that in our Whitehead tower $BO\langle k \rangle$ for $k = 10, 12$ is obtained by killing homotopy groups that are completely torsion. Hence rationally, $H^*(BO\langle k \rangle; \mathbb{Q}) \cong H^*(BFivebrane; \mathbb{Q})$ for $k = 10, 12$. So to follow along the lines of rational Fivebrane structures, we may define rational Ninebrane structures, and so on, for all the $k$-connected covers of $O$ which correspond to the killing of integral homotopy groups.

**Definition 19.** A rational Ninebrane structure is a lift of the 2Spin-principal bundle $\pi_{2\text{Spin}} : T \to M$ to the homotopy fiber $F(\frac{1}{2\pi^3} p_3)^Q$ of the rational classifying map $f : M \to B2\text{Spin}_Q$.

**Definition 20.** A rational Ninebrane class is a cohomology class $N_Q \in H^{11}(T; \mathbb{Q})$ such that $\iota^*_x N = a_{11} = \tau(\frac{1}{2\pi^3} p_3)^Q \in H^{11}(2\text{Spin}; \mathbb{Q})$ for each inclusion $\iota_x : 2\text{Spin} \to T$.

Now, just as we did in the case of Fivebrane structures, we will relate these classes to ones on the underlying Spin bundle. In order to do this, as we compared degree 7 rational cohomology between Spin and String we need to compare the degree 11 rational cohomology of Spin and 2Spin. Letting $\rho_0$ denote the homomorphism $\rho_0 : 2\text{Spin} \to \text{Spin}$, we consider here a principal 2Spin-bundle $T$ and let $Q$ again denote the induced principal Spin-bundle with a bundle map $\rho : T \to Q$ which is $\rho_0$-equivariant.

**Lemma 21.** The map $\rho_0 : 2\text{Spin} \to \text{Spin}$ induces an isomorphism $\rho^*_0 : H^{11}(\text{Spin}; \mathbb{Q}) \cong H^{11}(2\text{Spin}; \mathbb{Q})$.

**Proof.** We recall from Sec. 2.4 that the rational cohomology of Spin is given by the exterior algebra $\wedge \mathbb{Q}(x_3, x_7, x_{11}, \ldots)$. This gives a minimal model for Spin, and from the process of killing homotopy classes in the Whitehead tower, the CDGA $(\wedge \mathbb{Q}(x_{11}, x_{15}, \ldots), 0)$ provides a minimal model for 2Spin. Moreover, the map $\rho : 2\text{Spin} \to \text{Spin}$ induces a map $\rho^* : (\wedge \mathbb{Q}(x_3, x_7, x_{11}, \ldots), 0) \to (\wedge \mathbb{Q}(x_{11}, x_{15}, \ldots), 0)$ under which $\rho^*(x_k) = 0$ for $k = 3, 7$ and $\rho^*(x_{11}) = x_{11}$. Thus it follows that on the level of cohomology, $\rho^* : H^{11}(\text{Spin}; \mathbb{Q}) \to$
$H^{11}(2\text{Spin}; \mathbb{Q})$ is an isomorphism. Note that, for degree reasons, $x_{11}$ generates both degree 11 cohomology groups.

\[ \square \]

Now we can use Lemma 21 to relate rational Ninebrane classes to classes on the underlying Spin bundle.

**Definition 22.** A rational Spin-Ninebrane class is a cohomology class $\mathcal{N}_Q$ in $H^{11}(\mathbb{Q}; \mathbb{Q})$ such that $i_x^* \mathcal{N}_Q = \tilde{a}_{11} \in H^{11}(\text{Spin}; \mathbb{Q})$ for each $x \in M$.

We characterize these new classes as follows.

**Theorem 23.** Let $\pi_{2\text{Spin}} : P \to M$ be a principal 2Spin-bundle with $M$ simply connected and let $\pi_{\text{Spin}} : Q \to M$ be its underlying principal Spin-bundle. (i) For every rational Spin-Ninebrane class $\mathcal{N}_Q \in H^{11}(\mathbb{Q}; \mathbb{Q})$, the pullback $\rho^* \mathcal{N}_Q$ is a rational Ninebrane class.

(ii) Any rational Ninebrane structure $\mathcal{M}_Q \in H^{11}(T; \mathbb{Q})$ is the image $\mathcal{M}_Q = \rho^* \mathcal{N}_Q$ of a rational Spin-Ninebrane class $\mathcal{N}_Q \in H^{11}(\mathbb{Q}; \mathbb{Q})$.

(iii) Two classes $\mathcal{N}_Q, \mathcal{N}_Q' \in H^{11}(\mathbb{Q}; \mathbb{Q})$ will give the same rational Ninebrane structure if

\[ \mathcal{N}_Q - \mathcal{N}_Q' = S \cdot \pi_{\text{Spin}}^* \psi_8 + F \cdot \pi_{\text{Spin}}^* \phi_4, \]

where $S \in H^3(\mathbb{Q}; \mathbb{Q})$ is the String structure class, $F \in H^7(\mathbb{Q}; \mathbb{Q})$ is the Fivebrane structure class, $\psi_8 \in H^8(M; \mathbb{Q})$, and $\phi_4 \in H^4(M; \mathbb{Q})$ are rational cohomology classes.

Proof. The proof follows along similar lines as the proof of Theorem 17. Given a 2Spin-bundle $T$ over a manifold $M$, we have an induced Spin-bundle over $M$, by Lemma 21 induced by the fibration $\rho : 2\text{Spin} \to \text{Spin}$. By Lemma 21, we also know that this fibration induces an isomorphism on rational cohomology of degree 11. In keeping with our notation, we will denote this induced Spin bundle as $Q$. Now as before, we will compare the Serre spectral sequences corresponding to the rational cohomology for both bundles. As $H^k(2\text{Spin}; \mathbb{Q}) = 0$ for $0 < k < 11$, it follows easily that $H^{11}(T; \mathbb{Q}) = \mathbb{Q}[a_{11}] \oplus H^{11}(M; \mathbb{Q})$. Now for the bundle $Q$, the second page of the Serre spectral sequence is provided below.

We would like to calculate the entries $E^{p,q}_2$ such that $p + q = 11$. It follows immediately that $E^{2,9}_2 = E^{3,8}_2 = E^{5,6}_2 = E^{6,5}_2 = E^{7,4}_2 = E^{9,2}_2 = E^{10,1}_2 = 0$, and $E^{11,0}_2 = 0$ as $M$ is simply connected. Thus

\[ H^{11}(T; \mathbb{Q}) \cong E^{0,11}_2 \oplus E^{4,7}_2 \oplus E^{5,3}_2 \oplus E^{11,0}_2. \]

On inspection of the universal Spin bundle, we find that $d_4(a_3) = b_4$, $d_6(a_7) = b_8$, and $d_{12}(\tilde{a}_{11}) = b_{12}$, where $b_i \in H^i(B\text{Spin}; \mathbb{Q})$ and $\tilde{a}_i \in H^i(B\text{Spin}; \mathbb{Q})$ are generators. We also find that for all other possible differentials, $d_r(a_i) = 0$. Using functoriality of the differential maps and using the classifying map of $Q$ to compare with the universal Spin bundle, it follows that $d_r(a_3) = 0$ for $r \neq 4$, $d_r(a_7) = 0$ for $r \neq 8$, and $d_r(a_{11}) = 0$ for $r \neq 12$. 

19
Then we may proceed along the same lines as in Theorem \ref{thm:main} to identify the following pages

\[
\begin{align*}
E_{0,11}^0 & \cong \mathbb{Q}[a_{11}], & E_{4,7}^4 & \cong \mathbb{Q}[a_7] \otimes H^4(M; \mathbb{Q}), \\
E_{11,0}^{11} & \cong H^{11}(M; \mathbb{Q}), & E_{8,3}^{8,3} & \cong \mathbb{Q}[a_3] \otimes H^8(M; \mathbb{Q}),
\end{align*}
\]

from which the theorem follows. \hfill \Box

Remark 3. This theorem shows again that for Ninebrane structures most of the information is rationally encoded in the underlying Spin bundle. While the kernel of the map which assigns rational Spin-Ninebrane classes to rational Ninebrane classes is larger, we still have a surjection. In fact, this process should extend further to higher structures. The reason is that we are making use of the fact that, rationally, there is an isomorphism

\[
H^{12}(BSpin; \mathbb{Q})/(p_1^0, p_2^0) \cong H^{12}(B2Spin; \mathbb{Q})
\]

Through minimal models (see Sec. 2.3), it becomes clear that isomorphisms such as these continue to occur for higher connected covers of Spin. The difficulty in extending this definition then becomes more of a problem with determining the kernel of these maps.

Again, we have the following.

Corollary 24. If \( H^4(M; \mathbb{Z}) \) and \( H^8(M; \mathbb{Z}) \) are pure torsion, then the set of rational Ninebrane classes and rational Spin-Ninebrane classes are in bijective correspondence.

Example 10. We can give a nontrivial example of a manifold \( X \) which has torsion \( H^4(X; \mathbb{Z}) \), vanishing \( H^8(X; \mathbb{Z}) \) and non-torsion \( H^{12}(X; \mathbb{Z}) \). Let SU(2) be the subgroup of SU(4) consisting of all block diagonal matrices \( \text{diag}(A, A) \) where \( A \in \text{SU}(2) \). Then the 12-dimensional quotient \( X = \text{SU}(4)/\text{SU}(2) \), viewed as the base of an \( S^3 \) bundle, is stably parallelizable with \( H^4(X; \mathbb{Z}) = \mathbb{Z}_2 \), \( H^8(X; \mathbb{Z}) = 0 \) and \( H^{12}(X; \mathbb{Z}) = \mathbb{Z} \) [Si82, Lemma 6.5].

3.4. Gauge transformations. We now consider automorphisms of bundles equipped with the structures that we have just defined above. Let \( G \) be a topological group and \( G \to P \rightarrow X \) be a continuous \( G \)-principal bundle. Let \( G(P) \) be the gauge group of \( P \), i.e. the group of bundle automorphisms of \( P \). An
element \( \eta \in \mathcal{G}(P) \) is a bundle isomorphism of \( P \) that fits into the diagram (see e.g. [Co98])

\[
\begin{array}{ccc}
P & \xrightarrow{\eta} & P \\
\downarrow & & \downarrow \\
X & \rightarrow & X
\end{array}
\]

Equivalently, \( \mathcal{G}(P) \) is the group \( \mathcal{P} = \text{Aut}_G(P) \) of \( G \)-equivariant homeomorphisms of \( P \) covering the identity. If \( P \) is the trivial bundle \( X \times G \rightarrow X \) then \( \mathcal{G}(P) \) is given by the function space from \( X \) to \( G \), i.e. \( \mathcal{G}(P) \cong \text{Map}(X, G) \). When \( X \) has a basepoint \( x_0 \in X \), one can also consider the based gauge group \( \mathcal{G}_0(P) \), which is the subgroup of \( \mathcal{G}(P) \) whose elements fix the fiber \( P_{x_0} \), i.e.,

\[
\mathcal{G}_0(P) = \{ \eta \in \mathcal{G}(P) \mid \text{if } p \in P_{x_0} \text{ then } \eta(p) = p \}.
\]

In relation to Fivebrane and Spin-Fivebrane classes, we consider in general a principal \( O(k-1) \)-bundle. In the case where the structure group of this bundle lifts to \( O(k) \) then, as noted above in Sec. 3.2, these lifts are classified up to homotopy by classes in \( H^{k-1}(P; \pi_{k-1}(O)) \) which pull back under the fiber inclusion map \( \iota_x : P_x \rightarrow P \), for every \( x \in X \), to the class corresponding to a chosen generator of \( H^{k-1}(O(k-1); \pi_{k-1}(O)) \).

As gauge transformations describe homotopy equivalences (or even homeomorphisms) of the total space, the induced morphisms on cohomology are isomorphisms. Gauge transformations in the based gauge group fix the fiber over the basepoint of \( X \). Thus for \( \eta \in \mathcal{G}_0(P) \), we have \( \eta^* \iota_{x_0}^* = \iota_x^* \). Fixing an element in \( H^*(P; \pi_{k-1}(O)) \) and using that there is a canonical isomorphism between the cohomology of each fiber and the cohomology of \( O(k-1) \), we can view the pullback \( \iota_x^* \) as an assignment of a cohomology class in \( H^*(O(k-1), \pi_{k-1}(O)) \) to each element \( x \in X \).

**Proposition 25.** The unbased and based gauge groups of a Spin\((n/k)\)\(Q\) bundle over \( X \) are given by the mapping spaces

\[
\mathcal{G} \cong \text{Map}(X, \Pi_\alpha K(Q, m)) \quad \text{and} \quad \mathcal{G}_0 \cong \text{Map}_\alpha(X, \Pi_\alpha K(Q, m))
\]

**Proof.** This follows from various classical results in the literature as well as our earlier discussion in Sec. 2.2. Since all of our connected cover groups are rationally abelian, this means that the gauge groups, which are \( G \)-equivariant maps, become simply just maps, i.e. \( \mathcal{G} = \text{Map}(X, G) \). More precisely, the gauge transformations are \( G \)-equivariant homeomorphisms, which are equivalent to equivariant maps \( P \rightarrow G \) (where \( G \) acts on itself by conjugation), and since \( G \) is abelian, the map is constant on each fiber. Alternatively, the same holds, by [FO09 Cor 2.2], since all components of \( \text{Map}(X, BG) \) have the same homotopy type. Now we use the fact that \( G \cong \Pi K(Q, m_i) \) (see Prop. 3). A similar discussion holds for the based case. Note that this does not require any finiteness conditions on \( X \). \( \square \)

Note that the gauge groups arise as full spaces of maps rather than homotopy classes of maps, in which case the gauge group would have been some combination of cohomology classes. We will unpack some of these mapping spaces in order to appreciate the rich structure. We will first consider the more familiar Spin\(Q\) gauge transformations and ask whether they lift to String\(Q\) gauge transformations. To that end, consider the fibration \( K(Q, 2) \rightarrow \text{String}_Q \overset{p}{\twoheadrightarrow} \text{Spin}_Q \) and the corresponding lift

\[
\begin{array}{ccc}
X & \xrightarrow{u} & \\
\downarrow & \downarrow & \\
\text{String}_Q & \overset{p}{\twoheadrightarrow} & \text{Spin}_Q
\end{array}
\]
Hence we would like to consider the decomposition of the mapping space $\text{Map}(X, \text{String}_\mathbb{Q})$. Given a map $u : X \rightarrow \text{String}_\mathbb{Q}$, we define the mapping space $\text{Map}_u(X; \text{String}_\mathbb{Q}, \text{Spin}_\mathbb{Q})$ to be the space of all maps $f : X \rightarrow \text{String}_\mathbb{Q}$ such that $p \circ f = p \circ u = u_1$. The fibration $u^*_1(p)$ is a fiber homotopically trivial fibration $[\text{Th}57]$. Then $\text{Map}_u(X; \text{String}_\mathbb{Q}, \text{Spin}_\mathbb{Q}) \simeq \text{Map}_u(X, K(\mathbb{Q}, 2))$ for some map $u' : X \rightarrow K(\mathbb{Q}, 2)$, as $\text{Map}_u(X; \text{String}_\mathbb{Q}, \text{Spin}_\mathbb{Q})$ can be interpreted as a space of sections of $u^*_1(p)$, as in $[\text{Ma}87]$. Then, it follows from $[\text{Ha}82][\text{Ha}81][\text{Th}57]$ that the function space takes the form $\text{Map}_u(X; Y, B) = \prod_{i=0}^{n} K(H^{n-i}(X; G), i)$ when $Y \rightarrow B$ is a $K(G, n)$ fibration. Specializing to our case where we have $Y = \text{String}_\mathbb{Q}$, $B = \text{Spin}_\mathbb{Q}$, and the map $u$ corresponds to some rational String gauge transformation, we get the equivalence

$$
\text{Map}_u(X; \text{String}_\mathbb{Q}, \text{Spin}_\mathbb{Q}) \simeq \prod_{i=0}^{2} K(H^{2-i}(X; \mathbb{Q}), i).
$$

This then implies the following characterization of those gauge transformations that lift.

**Proposition 26.** If $X$ is 1-connected then $\text{Map}_u(X; \text{String}_\mathbb{Q}, \text{Spin}_\mathbb{Q}) \simeq H^2(X; \mathbb{Q}) \times K(\mathbb{Q}, 2)$.

**Example 11.** For $S^2$ we have $\text{Map}_u(S^2; \text{String}_\mathbb{Q}, \text{Spin}_\mathbb{Q}) \simeq K(\mathbb{Q}, 0) \times K(\mathbb{Q}, 2)$, while for $S^m$, $m > 2$ we have $\text{Map}_u(S^m; \text{String}_\mathbb{Q}, \text{Spin}_\mathbb{Q}) \simeq K(\mathbb{Q}, 2)$.

We can similarly consider the next two fibrations $K(\mathbb{Q}, 6) \rightarrow \text{Fivebrane}_\mathbb{Q} \rightarrow \text{String}_\mathbb{Q}$ and $K(\mathbb{Q}, 10) \rightarrow \text{Ninebrane}_\mathbb{Q} \rightarrow \text{Fivebrane}_\mathbb{Q}$. In these cases, the results in $[\text{Ha}82][\text{Ha}81][\text{Th}57]$ lead us to

$$
\text{Map}_u(X; \text{Fivebrane}_\mathbb{Q}, \text{String}_\mathbb{Q}) \simeq \prod_{i=0}^{6} K(H^{6-i}(X; \mathbb{Q}), i),
$$

$$
\text{Map}_u(X; \text{Ninebrane}_\mathbb{Q}, \text{Fivebrane}_\mathbb{Q}) \simeq \prod_{i=0}^{10} K(H^{10-i}(X; \mathbb{Q}), i).
$$

These are considerable spaces to deal with in practice and in applications. Nevertheless, we can get something tractable upon imposing some conditions.

**Proposition 27.** (i) If $X$ is 6-connected or if $H^i(X; \mathbb{Z})$ is pure torsion for $i \leq 6$, then given a rational String gauge transformation $u$, the space of lifts of $u$ to rational Fivebrane gauge transformations is given by $\text{Map}_u(X, \text{Fivebrane}_\mathbb{Q}, \text{String}_\mathbb{Q}) \simeq H^6(X; \mathbb{Q})$.

(ii) If $X$ is 10-connected or if $H^i(X; \mathbb{Z})$, $i \leq 10$ is pure torsion, then given a rational Fivebrane gauge transformation $u$, the space of lifts of $u$ to rational Ninebrane gauge transformations is given by $\text{Map}_u(X, \text{Ninebrane}_\mathbb{Q}, \text{Fivebrane}_\mathbb{Q}) \simeq H^{10}(X; \mathbb{Q})$.

**Example 12.** The String to Fivebrane gauge transformations for the case of $S^m$ for $m \geq 7$ are given as $K(\mathbb{Q}, 6)$, while for $S^6$ they are $K(\mathbb{Q}, 0) \times K(\mathbb{Q}, 6)$. Similarly, the Fivebrane to Ninebrane gauge transformations for the case of $S^m$ for $m \geq 11$ are given as $K(\mathbb{Q}, 10)$, while for $S^{10}$ they are $K(\mathbb{Q}, 0) \times K(\mathbb{Q}, 10)$.

In terms of classifying spaces, we can consider the fibration $K(\mathbb{Q}, 3) \rightarrow B\text{String}_\mathbb{Q} \xrightarrow{Bp} B\text{Spin}_\mathbb{Q}$. Given a principal String$_\mathbb{Q}$-bundle, we can consider its classifying map $f : X \rightarrow B\text{String}_\mathbb{Q}$. Then the mapping space $\text{Map}_f(X; B\text{String}_\mathbb{Q}, B\text{Spin}_\mathbb{Q})$ describes the space of all maps from $X$ to $B\text{String}_\mathbb{Q}$ which lift the map $Bp \circ f : X \rightarrow B\text{Spin}_\mathbb{Q}$, and we have

$$
\text{Map}_f(X; B\text{String}_\mathbb{Q}, B\text{Spin}_\mathbb{Q}) \simeq \prod_{i=0}^{3} K(H^{3-i}(X; \mathbb{Q}), i).
$$
Similarly, we can again consider the fibrations related to Fivebrane$_Q$ and Ninebrane$_Q$ (with the appropriate $f$) as above to obtain

\[
\text{Map}_f(X; B\text{Fivebrane}_Q, B\text{String}_Q) \simeq \prod_{i=0}^{7} K(H^{7-i}(X; Q), i) .
\]

\[
\text{Map}_f(X; B\text{Ninebrane}_Q, B\text{Fivebrane}_Q) \simeq \prod_{i=0}^{11} K(H^{11-i}(X; Q), i) .
\]

In general, as the rational homotopy groups $\pi_k(O)$ are $Q$ for $k \equiv 3 \mod 4$, and $0$ otherwise, then we can consider the set of lifts for a principal $O(4k-1)_Q$-bundle to a principal $O(4k+3)_Q$-bundle. We have fibrations $K(Q, 4k-1) \to BO(4k+4)_Q \overset{\xi_{4k+4}}{\to} BO(4k)_Q$. Then, using the fact that the fibrations associated with gauge transformations can be extended to classifying spaces [FO09], which we call “the space of $O(4k + 3)_Q$ structures”, we have the following.

**Proposition 28.** Let $f : X \to BO_Q(4k + 4)$ be a classifying map for an $O(4k + 3)_Q$-bundle over $X$. Then the space of $O(4k + 3)_Q$-structures on the underlying $O(4k - 1)_Q$-bundle is given by the space

\[
\text{Map}_f(X; BO(4k + 4)_Q, BO(4k)_Q) \simeq \prod_{i=0}^{4k-1} K(H^{4k-1-i}(X; Q), i) .
\]

Recall Proposition 9 which established that the set of isomorphism classes of $O(4k)$-structures is a torsor for $H^{4k-1}(X; \pi_{4k-1}(O))$. For rational structures, this proposition still holds where now the set of isomorphisms classes of $O(4k + 3)_Q$-structures is a torsor for $H^{4k-1}(X; Q)$. Now as isomorphic bundles have homotopic classifying maps, then we can equivalently interpret the set of isomorphism classes of $O(4k + 3)_Q$-structures lifting an $O(4k - 1)$ bundle as the connected components $\pi_0$ of $\text{Map}_f(X; BO(4k + 4)_Q, BO(4k)_Q)$. Using the homotopy equivalence of Prop. 28 we can explicitly calculate to find

\[
\pi_0(\text{Map}_f(X; BO(4k + 4)_Q, BO(4k)_Q)) \simeq \pi_0 \left( \prod_{i=0}^{4k-1} K(H^{4k-1-i}(X; Q), i) \right) \simeq H^{4k-1}(X; Q) .
\]

This agrees with Proposition 9.

**Remark 4.** (i) In relation to our previous discussion on rational Spin-Fivebrane structures in Sec. 3.2 we considered the problem of classifying Fivebrane structures on a principal String-bundle by classes on the underlying Spin-bundle. Following along this theme, we again consider a principal String$_Q$-bundle and its underlying Spin$_Q$-bundle, and we consider the maps $p' : \text{Fivebrane}_Q \to \text{String}_Q$ and $p : \text{String}_Q \to \text{Spin}_Q$. Then we have the classifying map $f : X \to B\text{String}_Q$ and composition with $Bp$ gives the classifying map for the principal Spin$_Q$-bundle. Suppose further that the classifying map $f$ lifts along $Bp'$ to a map $\tilde{f} : X \to B\text{Fivebrane}_Q$. Then the space $\text{Map}_f(X; B\text{Fivebrane}_Q, B\text{Spin}_Q)$ represents liftings of the underlying Spin$_Q$-bundle to a Fivebrane$_Q$ structure. It follows from [Mo87] that there is a fibration

\[
\text{Map}_f(X; B\text{Fivebrane}_Q, B\text{String}_Q) \to \text{Map}_f(X; B\text{Fivebrane}_Q, B\text{Spin}_Q) \to \text{Map}_f(X; B\text{String}_Q, B\text{Spin}_Q)
\]

(ii) Similarly, we consider what happens with gauge transformations. Let $u : X \to \text{Fivebrane}_Q$ be rational Fivebrane gauge transformation. Then there is a fibration

\[
\text{Map}_u(X; \text{Fivebrane}_Q, \text{String}_Q) \to \text{Map}_u(X; \text{Fivebrane}_Q, \text{Spin}_Q) \to \text{Map}_{pu}(X; \text{String}_Q, \text{Spin}_Q) .
\]

We now consider the rational homotopy groups of the gauge group $G$. In particular, we will consider instances when $G$ itself admits a (variant of) rational String, Fivebrane or Ninebrane cover. The following
results and examples can be generalized in straightforward ways; however, we pick the dimensions indicated as these seem to be most relevant for applications. The following few results are really corollaries of a slight generalization of one of the main results in [FO09] Theorem 3.1: If $X$ has the homotopy type of a CW complex then the homotopy groups of the gauge group are given as
\begin{equation}
\pi^Q_q(G(P)) \cong \sum_{r \geq 0} H^r(X; \mathbb{Q}) \otimes \pi^Q_{r+q}(G).
\end{equation}

(3.2)
\begin{equation}
\pi^Q_q(G_0(P)) \cong \sum_{r \geq 0} H^r(X; \mathbb{Q}) \otimes \pi^Q_{r+q}(G).
\end{equation}

The statement and proof given in [FO09] are for $G$ a Lie group. However, we observe that the proof goes through for our kind of abelian topological groups; in fact, it can also be deduced directly from Proposition 25. In our case, the relevant homotopy groups are $\pi^Q_4i-1(G)$ for $i \geq 1$. This then admits an interplay with $H^{4k}(X; \mathbb{Q})$, somewhat similar to the kind of relations we encountered in the variations of the Spin-Fivebrane and Spin-Ninebrane structures in Sec. 3.2 and Sec. 3.3.

**Proposition 29.** Let $P \to X$ be a principal $G$ bundle on an $n$-dimensional manifold $X$ where the group $G$ is $k$-connected. Then the gauge group $G(P)$ is $q$-connected where $q = k - n$.

Proof. This follows directly from the formula for the homotopy groups of the gauge group. For the values $q \leq k - n$, we have $\pi^Q_{q+r}(G) = 0$ by assumption and thus $\pi^Q_{r+q}(G) = 0$ for $r \leq n$. □

Specializing to the case where the group $G$ is a connected cover of $O(n)$, we notice that as a feature of Bott periodicity, the homotopy groups of the gauge group are periodic. As we noted above, Bott periodicity says that $\pi_i(O) = \pi_{i+4}(O)$ for all $i \geq 0$, and $\pi_i(O) = \mathbb{Q}$ for $i = 4k + 3$ and 0 everywhere else. This translates to gauge groups as follows.

**Proposition 30.** Consider a principal $G$-bundle $P \to X$ where $G = O(k)\mathbb{Q}$. The homotopy groups of the gauge group $G(P)$ satisfy the following periodicity conditions
\begin{equation}
\pi_q(G(P)) = \pi_{q+4}(G(P)) \quad \text{and} \quad \pi_q(G_0(P)) = \pi_{q+4}(G_0(P))
\end{equation}
for every $q \geq k$.

Proof. For the case of $G = \text{Spin}_\mathbb{Q}$, following equation (3.1) we calculate the first four homotopy groups
\begin{align*}
\pi^Q_1(G(P)) &\cong \sum_{r \geq 0} H^{4r+2}(X; \mathbb{Q}) \otimes \pi^Q_{4r+3}(G), \\
\pi^Q_2(G(P)) &\cong \sum_{r \geq 0} H^{4r+1}(X; \mathbb{Q}) \otimes \pi^Q_{4r+3}(G), \\
\pi^Q_3(G(P)) &\cong \sum_{r \geq 0} H^{4r}(X; \mathbb{Q}) \otimes \pi^Q_{4r+3}(G), \\
\pi^Q_4(G(P)) &\cong \sum_{r \geq 0} H^{4r-1}(X; \mathbb{Q}) \otimes \pi^Q_{4r+3}(G),
\end{align*}
and use Bott periodicity. In calculating $\pi_5$, noting that $\pi_5(G) = \pi_1(G) = \mathbb{Q}$, we get $\pi_5(G(P)) = \pi_1(G(P))$.

In general, if $L = q \mod(4)$, then $\pi_{r+q}(G)$ is non zero for $r = 4i + 3 - L \geq 0$. We further note that as $H^r(X; \mathbb{Q})$ is a $\mathbb{Q}$-vector space then tensoring by $\mathbb{Q}$ induces an isomorphism. Thus for general $q$ we have
\begin{equation}
\pi^Q_q(G(P)) \cong \sum_{r \geq 0} H^{4r+3-L}(X; \mathbb{Q}) \otimes \pi_{4r+3-L+q}(G) \cong \sum_{r \geq 0} H^{4r+3-L}(X; \mathbb{Q}),
\end{equation}
and as $q-L = 0 \mod(4)$, then this equation only depends on $q$ modulo 4 and the periodicity result follows.

Now we consider the case where $G = \text{Spin}(k)\mathbb{Q}$. Thus $\pi_i(G) = 0$ for $i < k$. Equation (3.3) still holds as long as $3-L+q \geq k$. Since $3-L \geq 0$, it follows that $q \geq k$. The proof for the based gauge group is identical. □
We observe that requiring the gauge group to be higher connected places conditions both on the underlying space $X$ as well as on lifting the structure group $G$, taken here to be a priori the Spin group, in the following sense.

**Corollary 31** (String cover of the gauge group). The gauge group $G$ for Spin bundles over $X$ is rationally 3-connected in the following cases:

(i) If $\dim X \leq 3$ and $G$ is the rational String group.

(ii) If $\dim X \leq 7$ and $G$ is the rational Fivebrane group.

(iii) If $\dim X \leq 11$ and $G$ is the rational Ninebrane group.

Proof. The homotopy groups through degree three of the rational gauge group from $\mathbf{F} \circ \mathbf{O}$ takes the form

$$
\sum_{i=0}^{3} \pi_{i}^{Q}(G(P)) \cong \sum_{i=0}^{3} H^i(X;\mathbb{Q}) \otimes \pi_{i}^{Q}(G) \oplus \sum_{i=0}^{3} H^{i+1}(X;\mathbb{Q}) \otimes \pi_{i}^{Q}(G) \oplus \sum_{i=0}^{3} H^{8+i}(X;\mathbb{Q}) \otimes \pi_{i}^{Q}(G) \oplus \cdots .
$$

The statements then follow from imposing the condition on $\pi_{i}(G)$. The condition on $X$ ensures that higher terms do not contribute. \( \square \)

Note that one cannot dispose of all conditions on $G$ in favor of conditions only on $X$ because of the presence of $H^0(X;\mathbb{Q})$ in the formula. The situation is a little improved when considering exceptional groups.

**Example 13.** Consider an $E_8$ bundle $E$ on a manifold $X$ of dimension $n \leq 12$. Since the first non-torsion homotopy group after $\pi_3(E_8)$ is $\pi_{15}(E_8)$ then if $X$ is 3-connected, the based gauge group $\mathcal{G}(E)$ is $(15-n)$-connected. It is interesting to note that, in particular, for $M$-theory extended to twelve dimensions, the based gauge group is lifted to its 3-connected, i.e. String, cover.

For certain nice spaces $X$ the description is more pleasant. Consider for example the $m$-sphere $S^m$.

**Example 14** (Gauge groups of bundles over spheres). Consider a $G$-principal bundle $G \to P \to S^m$ over the $m$-sphere. Then the homotopy groups are shown in $\mathbf{W} \circ \mathbf{O}$ to be related as $\pi_{n}^{Q}(G(P)) \cong \pi_{n+m}^{Q}(G) \oplus \pi_{n}^{Q}(G)$.

(i) For $S^4$, the gauge group $\mathcal{G}(P)$ is rationally 3-connected if $G$ is rationally 7-connected.

(ii) For $S^8$, the gauge group $\mathcal{G}(P)$ is rationally 3-connected if $G$ is rationally 11-connected.

We can also study the homotopy groups of the universal bundles.

**Example 15.** Consider the universal bundle $\text{Spin} \to E\text{Spin} \xrightarrow{\xi} B\text{Spin}$. Then, applying $\mathbf{F} \circ \mathbf{O}$ Thm. 4.2, leads to $\pi_{n}^{Q}(G(\xi_n)) = \sum_{i \geq 0} H^i(B\text{Spin};\mathbb{Q}) \otimes \pi_{n+i}(\text{Spin})$. Now since the non-torsion generators of the cohomology of $B\text{Spin}$ occur only in degrees that are multiples of 4 and since, by transgression, the non-torsion homotopy groups are in degrees $4n + 3$, it follows that $\mathcal{G}(\xi_n)$ is 2-connected. Applying Proposition 36 it follows that $\pi_k^{Q}(G(\xi_n)) = 0$ if $k \neq 4n + 3$.

**Remark 5.** The formulation of the rational gauge group as the rational mapping space $\text{Map}(X, G)$ comes close to the formulation via (topological or smooth) stacks. Indeed, in stacks one builds a global object by starting from open subsets of $X$ and intersections thereof into $G$. The group $G$ can be taken to be a higher group, i.e. an $n$-group, which model the connected cover groups that we consider here. However, as we discussed in the Introduction, the aim is to keep our tools as classical as possible in this paper.

**Acknowledgement.** The authors would like to thank Corbett Redden for useful discussions and suggestions especially at the initial stages of this project, and Sadok Kallel, Mark Grant, Paolo Salvatore, and Sam Smith for useful comments. We are indebted to the anonymous referee for the many helpful suggestions that have significantly improved the paper.
