Abstract

Coreset (or core-set) is a small weighted subset $Q$ of an input set $P$ with respect to a given monotonic function $f : \mathbb{R} \to \mathbb{R}$ that provably approximates its fitting loss $\sum_{p \in P} f(p \cdot x)$ to any given $x \in \mathbb{R}^d$. Using $Q$ we can obtain approximation of $x^*$ that minimizes this loss, by running existing optimization algorithms on $Q$. In this work we provide: (i) A lower bound which proves that there are sets with no coresets smaller than $n = |P|$ for general monotonic loss functions. (ii) A proof that, under a natural assumption that holds e.g. for logistic regression and the sigmoid activation functions, a small coreset exists for any input $P$. (iii) A generic coreset construction algorithm that computes such a small coreset $Q$ in $O(nd + n \log n)$ time, and (iv) Experimental results with open-source code which demonstrate that our coresets are effective and are much smaller in practice than predicted in theory.

1 Introduction

Traditional algorithms in computer science and machine learning are usually tailored to handle off-line finite datasets that are stored in memory. However, many modern systems do not use this computational model. For example, GPS data from millions of smartphones, high definition images, YouTube videos, Twitter tweets, or audio signals from smart homes arrive in a streaming fashion. The era of Internet of Things (IoT) provides us with wearable devices and mini-computers that collect data sets that are being gathered by ubiquitous information-sensing mobile devices and wireless sensor networks [19, 31, 14].

Challenges. Using such devices and networks pose a series of challenges:

(i) Limited memory. In such systems, the input is an infinite stream of batches that may grow in practice to petabytes of raw data, and cannot be stored in memory. Hence, only one-pass over the data and small memory are allowed.

(ii) Parallel computations. To leverage the power of multithreading and multiple processing units (as in GPUs), we are required to design variants of our algorithms which can run in parallel.

(iii) Distributed computations. If the dataset is distributed among many machines, e.g. on a “cloud”, there is an additional problem of non-shared memory, which may be replaced by expensive and slow communication between the machines.

Weak or no theoretical guarantees. Due to the modern computation models above, learning trivial properties of the data may become non trivial, as stated in [14]. These problems are especially common in machine learning applications, where the common optimization problems and models may be, already in the off-line settings NP-hard. The result is neglecting, in some sense, decades of theoretical computer science research, and replacing it by fast heuristics and ad-hoc rules, which are easy to implement under the above constrains, and provide reasonable results. Those heuristics, however, have no theoretical guarantees, either as of running time or of global optimality.
1.1 Coresets

Coresets suggest a natural solution or at least a very generic approach to address the above challenges without re-inventing computer science. Coresets have some promising theoretical guarantees, while still leveraging the success of existing heuristics. Instead of designing, from scratch, a new algorithm to solve the problem at hand, the idea is to provably summarize the data into a small representative subset, and to prove that applying existing algorithms, both heuristics and provable methods, on this small summarizations, will yield an output which approximates the result of running the same algorithms on the original (full) data.

In this paper we focus on coresets for monotonic continuous functions, that is: we assume that we are given a set $P$ of $n$ points in $\mathbb{R}^d$, and a non-decreasing monotonic functions $f : \mathbb{R} \to \mathbb{R}_{>0}$. For a given error parameter $\varepsilon \in (0,1)$, we wish to compute an $\varepsilon$-coreset $Q \subseteq P$, with a weight function $u : Q \to [0, \infty)$ that provably approximates the fitting cost of $P$ for every $x \in \mathbb{R}^d$, up to a multiplicative factor of $1 + \varepsilon$, i.e., $(1 - \varepsilon) \sum_{p \in P} f(p \cdot x) \leq \sum_{q \in Q} w(q)f(q \cdot x) \leq (1 + \varepsilon) \sum_{p \in P} f(p \cdot x)$. Although it seems rather theoretic, many real world problems can be formulated using such functions, including the Sigmoid, Logistic regression, SVM, Linear classifiers, and Gaussian Mixture Models; see examples in [10].

Coresets and machine learning. We can use the notion of coresets as described above for improving the performance of machine learning algorithms. Most machine learning algorithms essentially solve an optimization problem over some set of training data. By constructing a coreset for this training data, we can: (i) greatly reduce the time it takes to train a model, simply by training it on the (small) coreset, and (ii) allow support for streaming, parallel, and distributed data. Although the coreset provides guarantees for the approximation of the MSE of the training data, it can be shown that for some problems, a coreset can also provide guarantee for the approximations of the generalizations error. For example, when using Bayesian inference, it was shown in [20] that a model which is based on coreset for the log likelihood function, has a marginal likelihood which is guaranteed to approximate the true marginal likelihood. The same can be shown for maximum likelihood estimation. The popular measure for the goodness of fit of an estimator is the the log-likelihood ratio:

$$
\ln \Lambda(\theta) = \mathcal{L}(\hat{\theta}) - \sup_{\theta \in \Theta} \mathcal{L}(\theta).
$$

The log-likelihood ratio of a model which is based on a coreset, uniformly approximates the log-likelihood ratio of the full model. Furthermore, coresets have been shown to practically improve the generalization error for machine learning algorithms [20, 11, 28].

1.2 Our contribution

(i) We provide an impossibility bound that proves that, for non-decreasing monotonic loss function, there are no small coresets in general. We do this by providing an example of an input set of points $P$, for which no coreset of size smaller than $|P|$ exists; see Section 3.

(ii) Following the bound above, we can either give up on the generic coreset paradigm, or add natural assumptions and modifications to the targeted functions $f$. In this paper we choose the second option; We add a regularization term to the loss function, which, in most cases, is added anyway to avoid overfitting [30, 14]. In fact, in some cases, this new term is crucial as some functions are minimized only for $x$ approaching infinity if this term is omitted. For example, the regularization term we add to the sigmoid function is $||x||^2 / k$, where $k > 0$ defines the trade-off between minimizing the function and the complexity of the set of parameters. While minimizing such functions may still be NP-hard [32], we prove that a small coreset $Q$ exists for any input set $P$, for the sigmoid and logistic regression functions; see Section 5. However, the proof holds for a wider family of functions.

(iii) We provide a generic algorithm that computes the coreset $Q$ above in $O(nd + n \log n)$ time. Unlike most existing works, our algorithm can construct a coreset for the sigmoid and logistic regression functions, as well as a wider set of functions; see Algorithm 1.

(iv) Open source code for our algorithms is given [5], along with extensive experimental results on both synthetic and real-world public datasets; see Section 6.

1.3 Related Work

In [17], Har-Peled shows how to construct a coreset of one dimensional points sets ($d = 1$) for sums of single variable real valued functions. In the scope of machine learning most of the research involves
clustering techniques [15] [16] [13] and regressions [3] [8] [39]. Several coresets were constructed for unsupervised learning problems including coresets for Gaussian mixture models [11], and SVM [33] [18]. Other works handle general families of supervised learning problems [34] [25].

The work by [20] introduces lower bounds on the total sensitivity of the logistic regression problem that is used in this paper. It also introduces an upper bound for the total sensitivity and coreset size based on \( k \)-clustering coresets. However the bounds hold only for input set \( P \) from very specific distributions (roughly, when \( P \) is well separated into \( k \) clusters).

In [28], a lower bound of \( \Omega (n / \log n) \) points, on the size of a coreset for a two dimensional logistic regression was introduced. To find a coreset, the authors have introduced a measure of the data \( \mu \), which depends on the log-ratio between the positive and negative labeled points, and have shown that for data sets in which \( \mu \) is sufficiently small a coreset of size \( O (\text{poly} (\log n)) \) exist. Instead of imposing assumptions on the above input-related measure, in this work we add a regularization term to the loss function which, as we show, makes the coreset construction task feasible. There does not seem to be a direct relation between our work and the measure \( \mu \) used in [28].

The main tool of this work uses the unified framework presented in [12], which was recently improved in [4]. We also use the reduction from \( \mathcal{L}_\infty \) coresets that approximates \( \max_{p \in P} f (p : x) \) to our \( \mathcal{L}_1 \) coreset (sum of loss) which was introduced in [37].

### 1.4 Paper Organization

Section 2 describes preliminary results which we utilize in our coreset construction algorithm. In Section 3 we give examples of input sets which have no non-trivial coreset (i.e., smaller than the input size), for general monotonic functions. In Section 4 we introduce our main coreset construction algorithm. We then prove the correctness of this algorithm for the sigmoid and logistic regression activation functions. In Section 6 we provide our experimental results along with a discussion.

### 2 Preliminaries

In what follows we first describe the coreset construction framework of [12]. The framework is based on a non-uniform sampling of the input, according to some importance distribution over the input points. This distribution assigns higher values to points of higher influence on the optimization problem at hand. Now, in order to keep the sample unbiased, the sampled points are reweighted reciprocal to their sampling probability. To quantify the influence of a single point on the optimization problem, Feldman and Langberg suggested in [23] a term called sensitivity, which we define later in this section. Using the sensitivity, a sampling-based coreset can be constructed, whose size depends on the total sensitivity over the input points, a complexity measure of the family of models, called the VC-dimension, and an error parameter \( \varepsilon \). To approximate the total cost \( C (P, w, x) \) of the input \( (P, w) \), for every

\[
L \subseteq P, Q \subseteq P \subseteq \mathbb{R}, \quad \sum_{x \in X} \max_{p \in P} f (p : x) \leq \mathcal{L}^* (Q, u) = \sum_{p \in P} \mathcal{L} (p) s (p).
\]
query \( x \in X \), up to a multiplicative factor of \( 1 \pm \varepsilon \). Such a set, which we call a coreset, is defined as follows.

**Definition 2** (\( \varepsilon \)-coreset). Let \( (P, w, X, c) \) be a query space (see Definition 1), and \( \varepsilon \in (0, 1) \) be an error parameter. An \( \varepsilon \)-coreset for \( (P, w, X, c) \) is a weighted set \( (Q, u) \) such that for every \( x \in X \),

\[
\sum_{p \in P} w(p) c(p, x) - \sum_{q \in Q} u(q) c(q, x) \leq \varepsilon \cdot \sum_{p \in P} w(p)c(p, x).
\]

In [12], a lower bound is given for the required coreset size, as a function of the total sensitivity \( t(P) \). This bound was later made tighter in [4]. The following theorem describes the random sampling scheme for coreset construction using the sensitivity framework, and describes the required sample (coreset) size.

**Theorem 3** (coreset construction [4, 12]). Let \( (P, w, X, c) \) be a query space of VC-dimension \( d \) and total sensitivity \( t \). Let \( \varepsilon, \delta \in (0, 1) \). Let \( Q \) be a random sample of \( |Q| \geq \frac{10n}{(d \log t + \log (\frac{1}{\delta}))} \) i.i.d points from \( P \), such that every \( p \in P \) is sampled with probability \( \frac{1}{t} \cdot sp_{P,w,X,c}(p) \). Let \( u(p) = \frac{t \cdot w(p)}{s_{P,w,X,c}(p) |Q|} \) for every \( p \in Q \). Then, with probability at least \( 1 - \delta \), \((Q, u)\) is an \( \varepsilon \)-coreset of \((P, w, X, c)\).

### 3 Lower Bounds

In what follows, we consider query spaces \((P, w, \mathbb{R}^d, c)\), where \( c(x, p) = f(x \cdot p) \) for some non-decreasing monotonic function \( f \). We prove that not all such query spaces admit a non-trivial coreset, by providing an example of an input sets \( P \) for which every coreset must be of size \(|P|\).

**No coreset.** Consider a 2-dimensional circle \( C \subseteq \mathbb{R}^3 \) in 3-dimensional space, which is the intersection of the unit sphere and a non-affine plane (does not pass through the origin) that is parallel to the \( XY \) plane. For every point \( p \in P \), let \( \pi_p \) be a plane in \( \mathbb{R}^3 \) that passes through the origin which isolates \( p \) from the rest of the set, and let \( x_p \) be a vector orthogonal to \( \pi_p \), such that \( p \cdot x_p > 0 \); see Fig 1. Such a plane exists since the points are on a 2D circle that is not centered around the origin.

Now, for intuition, consider the logistic regression cost function: \( c(x, p) = \log(1 + e^{p \cdot x}) \). Let \( p \in P \) and let \( x_p \) be the query vector orthogonal to the plane \( \pi_p \) which separates \( p \) from the rest of the set. Since \( p \) is the only point on the positive side of \( x_p \), it holds that \( p \cdot x_p > 0 \) whereas for every other point \( p' \), \( p' \cdot x_p < 0 \). Moreover as \( ||x_p|| \) grows, \( p \cdot x_p \) goes to \( \infty \) and \( p' \cdot x_p \) grows to \( -\infty \). Thus the cost \( c(x_p, p) = \log(1 + e^{p \cdot x_p}) \) of \( p \), goes to \( \infty \) and the cost of every other point goes to 0. Therefore, \( p \) has a sensitivity of 1. In this case, intuitively, every coreset must include \( p \) or else it cannot provide a good approximation to the cost of the original (full) set. Since this argument holds for every \( p \in P \), any coreset for \( P \) must include all points in \( P \). Thus, no non-trivial coreset exists in this case. Putting, it differently, the above discussion shows that if the sensitivity of every point in \( P \) is 1 then the size of every coreset is \( \Omega(n) \); see Lemma [11] in the supplementary material for a formal statement.

Figure 1: (Left): A set of points \( P \) in \( \mathbb{R}^3 \) (red and green points), a plane \( \pi_p \) separating \( p \) from \( P \setminus \{p\} \) and the vector \( x_p \) orthogonal to \( \pi_p \). (Right): A top-down view of the data on the left. The dotted line \( \ell \) is the intersection of \( \pi_p \) and the plane containing \( P \). All the points to the right (left) of \( \ell \) are projected onto the positive (negative) side of \( x_p \).
Note that the above holds true not only for logistic regression but for any function $f$ that satisfies $\lim_{x \to \infty} \frac{f(-x)}{f(x)} = 0$. This is formally stated in the following theorem. A formal proof is given in Section A of the supplementary material.

**Theorem 4.** Let $f : \mathbb{R} \to (0, \infty)$ be a non-decreasing monotonic function that satisfies $\lim_{x \to \infty} \frac{f(-x)}{f(x)} = 0$, and let $c(x, p) = f(x \cdot p)$ for every $x, p \in \mathbb{R}^d$. Let $\varepsilon \in (0, 1)$, $n \geq 1$ be an integer, and $w : \mathbb{R}^d \to (0, \infty)$. There is a set $P \subset \mathbb{R}^d$ of $|P| = n$ points such that if $(Q, u)$ is an $\varepsilon$-coreset of $(P, w, \mathbb{R}^d, c)$ then $Q = P$.

**Adding assumptions.** The above counter-example and formal claim motivate the necessity of adding assumptions on the loss function, as described in the following section. Mainly, a regularization term needs to be added. This term is usually added anyway, both in theory and in practice, to reduce the complexity of the model and avoid overfitting.

## 4 Coresets For Monotonic Bounded Functions

From the previous section, we conclude that an additional constraint must be imposed on the problem at hand in order to construct a small coreset. To better understand the required constraint, recall the reason for the lower bound from the example at Section 3; the (problematic) points with sensitivity $1$ were the points which had very large values of $x \cdot p$. This can happen when $\|x\|$ is very large or when $\|p\|$ is large. For the moment, assume that $\|p\|$ is small (we will later see how $\|p\|$ affects the size of the coreset). The standard technique for preventing the parameters from growing too large is to add a regularization term, which is widely used in many real world problems [30, 22].

As it happens to be, adding a regularization term also advances us towards our goal of constructing a coreset, as was also noted e.g., in [29, 35]. To see this, consider a regularized variant of the loss function: $c(x, p) = f(x \cdot p) + \frac{\|x\|^2}{b}$. Since $f$ is bounded, when $\|x\|$ grows to infinity the value of the regularization dominates the loss. Thus, in this case, all points have approximately the same loss, and are all equally unimportant. In other words, the sensitivity of those points can not be $1$.

The common case for the value of the regularization parameter $k$ is $k = n^{1-\kappa}$ for $\kappa \in (0, 1)$; see e.g., in [7, 26]. In practice, we observed that the values of $k$ have only a small effect on the coresets approximation accuracy; see Section 5.

### 4.1 $L_\infty$ coresets

We now address the common case, in which for some $x \in X$ and every two points, $p_1, p_2 \in P$ the values of $p_1 \cdot x$ and $p_2 \cdot x$ do not greatly differ. To do so, we will reduce our problem to the problem of constructing an $L_\infty$ coreset, which is defined as follows.

**Definition 5.** ($L_\infty$ coreset [27]) Let $(P, w, X, c)$ be a query space and $\varepsilon > 0$. An $\varepsilon - L_\infty$ coreset is a subset $Q \subseteq P$ such that $\max_{p \in P} c(p, x) \leq (1 + \varepsilon) \max_{q \in Q} c(q, x)$ for every $x \in X$.

We will now focus on constructing an $L_\infty$ coreset. We will then show how to leverage this $L_\infty$ coreset to obtain a coreset as defined in Definition 2.

Consider a monotonic non-decreasing function $f : \mathbb{R} \to (0, M]$, a query $x \in X$ and a point $p \in P$ such that $p \cdot x > 0$. Since $f$ is a monotonic function, $f(0) \leq f(p \cdot x)$. Hence,

$$\max_{p \in P} f(p' \cdot x) \leq M = \frac{M}{f(0)} f(0) \leq \frac{M}{f(0)} f(p \cdot x),$$

Therefore, for a query $x$, if a point $p$ falls on the positive side of the line defined by $x$ we can say this point is an $L_\infty$ coreset. But what if the point falls on the negative side of the line? Since $f$ is monotonic, we know that if $p \cdot x < 0$ then, $f(p \cdot x) < f(-p \cdot x)$, but if $f$ is sufficiently “well behaved” then as long as the distance between $-p \cdot x$ and $p \cdot x$ is not too large, then the distance between $f(-p \cdot x)$ and $f(p \cdot x)$ is also bounded. Specifically, we can assume there is a constant $b > 0$ such that

$$f(-p \cdot x) < b \cdot f(p \cdot x)$$

which implies that even if $p$ falls on the negative side of the line, then $p$ is an $L_\infty$ coreset.
Assumptions and conclusions made so far. Before we conclude the results of this section, we must conduct the assumptions and conclusions we have made so far. We have assumed that the distance between \(-p \cdot x\) and \(p \cdot x\) is not too large. We can bound the distance as follows:

\[
| -p \cdot x - (p \cdot x) | = | 2p \cdot x | \leq 2 \|x\| \|p\|.
\]

From the discussion in the beginning of the section, adding regularization will guarantee that \(\|x\|\) cannot grow arbitrarily large. As for the \(\|p\|\) term, we expect the coreset to be somehow affected by this term in order to ensure the above property. Indeed, this is one of the main terms which affect the sensitivity of the input points. Hence, the final coreset will be more likely to choose points with larger norm.

We conclude that every point \(p \in P\) is an \(\varepsilon - L_\infty\) coreset for sufficiently large \(\varepsilon\) that depends on properties of the function \((M, f(0)\) and \(b)\) and on \(\|p\|\). This is formally stated in the following lemma.

**Lemma 6 (L_\infty coresets).** Let \(P \subset \mathbb{R}^d\) be a finite set, \(M, k > 0\) be constants, \(f : \mathbb{R} \to (0, M]\) be non-decreasing function and \(g : [0, \infty) \to [0, \infty)\) be a function. For every \(x \in \mathbb{R}^d\) and \(p \in P\) define \(c_k(p, x) = f(p \cdot x) + g(\|x\|)\). Put \(p \in P\) and suppose there is \(b_p > 0\) such that for every \(z > 0\), \(f(\|p\|, z) + g(z) \leq b_p (f(-\|p\|, z) + g(z))\). Then \(\{p\}\) is an \(\varepsilon - L_\infty\) coreset with \(\varepsilon = \frac{M}{f(0)} b_p + 1 - 1\).

**Algorithm 1 MONOTONIC-CORESET(P, k, m)**

1: **Input:** A set \(P = \{p_1, \ldots, p_n\}\) of points in \(\mathbb{R}^d\),
a real valued regularization term \(k > 0\), and
an integer \(m \geq 1\).
2: **Output:** A pair \((Q, u)\) where \(|Q| = m\) and \(u : Q \to [0, \infty)\); see Theorems\[9, 10\]
3: Sort the points in \(P = \{p_1, \ldots, p_n\}\) by their length, i.e., \(\|p_1\| \leq \cdots \leq \|p_n\|\).
4: \(s(p_i) := c \cdot \sqrt{k \|p_i\|} + 2\) for every \(i \in [n]\) \((c\) is a sufficiently large constant.\)
5: Set \(t \leftarrow \sum_{i=1}^n s(p_i)\)
6: Pick an i.i.d random sample \(Q \subseteq P\) of \(|Q| = m\)\(\min \{m, n\}\) from \(P\), where every \(p \in P\) is chosen with probability \(s(p)/t\).
7: \(u(p) := \frac{1}{|Q|} \text{Prob}(p)\) for every \(p \in Q\)
8: **return** \((Q, u)\)

4.2 From \(L_\infty\) coresets to coresets

We now describe how to leverage an \(L_\infty\) coreset to bound the sensitivity of every input point.

**Intuition behind Algorithm**[1] Let \(Q\) be an \(\varepsilon - L_\infty\) coreset of \(P\). Intuitively, since the points in \(Q\) provide a \((1 + \varepsilon)\)-approximation to the maximal cost, we would require a random sampling scheme to choose these points with relatively high probability (compared to points in \(P\) \(\setminus Q\)). Let \(Q_2\) be an \(\varepsilon - L_\infty\) coreset of \(P\) \(\setminus Q\). Using the same reasoning, we would require the probability of sampling points in \(Q_2\) to be greater than the probability of sampling a point in \(P\) \(\setminus Q_2\), but less than the probability of sampling a point in \(Q\). Using this logic, we can continue to construct \(L_\infty\) coresets and remove them from the set of remaining points. The probability of every point \(p \in P\) should intuitively be proportional to \(\frac{1}{z}\), where \(i\) is the index of the \(L_\infty\) coreset which contains \(p\). Phrasing this differently: for every \(p\), the sensitivity of \(p\) is proportional to \(\frac{1}{z}\). In [57] it was proven that by repeatedly constructing \(L_\infty\) coresets as described above, one can bound the total sensitivity and construct a coreset. Fig. 2 illustrates the above reduction.

The following lemma gives the formal statement for the algorithm described above. The lemma is based on Lemma 3.1 in [57].

**Lemma 7.** Let \(c : \mathbb{R}^d \times \mathbb{R}^d \to (0, \infty)\). Suppose that for some \(\varepsilon \in (0, 1)\) there is a non-decreasing function \(\Delta_\varepsilon(n)\) so that for any \(P' \subseteq \mathbb{R}^d\) of size \(n\) there is an \(\varepsilon - L_\infty\) coreset of size at most \(\Delta_\varepsilon(n)\) for \((P', 1, \mathbb{R}^d, c)\). Then, for any \(P \subseteq \mathbb{R}^d\) of size \(n\) we can compute an upper bound \(s(p)\) on the sensitivity \(s_{P, 1, \mathbb{R}^d, c}(p)\) for each \(p \in P\), so that \(\sum_{p \in P} s_{P, 1, \mathbb{R}^d, c}(p) \leq (1 + \varepsilon)\Delta_\varepsilon(n)\ln n\).
Theorem 8. Let \( M, k > 0 \) be constants, \( P \subseteq \mathbb{R}^d \) be a set of points, \( f : \mathbb{R} \to (0, M] \) be a monotonic non-decreasing function, and \( c_k(p', x) = f(p' \cdot x) + \frac{g(|x|)}{k} \) for every \( x \in \mathbb{R}^d \) and \( p' \in P \). Suppose there is \( b : P \to (0, \infty) \) such that for every \( p \in P \) and every \( z > 0 \) we have \( f(\|p\| z) + \frac{g(z)}{k} \leq b(p) \left( f(-\|p\| z) + \frac{g(z)}{k} \right) \). Let \( b_{\text{max}} \in \arg \max_{p \in P} b(p) \), \( t = (1 + \frac{M}{b_{\text{max}}}) \ln n \), and \( \varepsilon, \delta \in (0, 1) \). Lastly, let \( d_{\text{VC}} \) be the VC-dimension of \((P, 1, \mathbb{R}^d, c_k)\). Then, there is a weighted set \((Q, u)\), where \( Q \subseteq P \) and \(|Q| \in O \left( \frac{1}{\varepsilon^2} (d_{\text{VC}} \log t + \log \frac{1}{\delta}) \right) \), such that with probability at least \( 1 - \delta \), \((Q, u)\) is an \( \varepsilon \)-coreset for the query space \((P, 1, \mathbb{R}^d, c_k)\).

Discussion behind Theorem 8. The above theorem suggests a sufficient condition for the existence of a coreset, in the case of a monotonic non-decreasing function \( f \), to which a regularization term is added. The proof of this theorem is constructive; it combines the above condition with Lemma 7 in order to bound the sensitivity of every input point \( p \in P \) and also gives an upper bound to the total sensitivity; see Section B.2 of the supplementary material. As an example, the following section constructs a coreset for the sigmoid and logistic regression activation functions by proving that the above condition is indeed met. However, the above theorem is not limited to those activation functions, and can be utilized for many other functions. Given this sensitivity upper bound, the coreset construction algorithm is straightforward: it simply samples the input set \( P \) based on the sensitivity distribution, and assigns appropriate weights to the sampled points. The only thing left to determine is the sample size required in order to achieve some predefined approximation error \( \varepsilon \). A suggested implementation for the sigmoid and logistic regression functions is given in Algorithm 1.

5 Example Applications - Coresets for Sigmoid and Logistic Regression

In this section, we leverage the framework derived in the previous section in order to construct, as an example, a coreset for the sigmoid and logistic regression activations; see Theorems 9 and 10 respectively. The full proofs are placed in Section C.2 of the supplementary material.

Overview of Theorems 9[10] The following theorems construct a coreset for sums of sigmoid functions and for the logistic regression log-likelihood, for normalized input sets. To do so, we: (i) prove that the sufficient condition from Lemma 6 and Theorem 8 in the previous section is met for both the sigmoid and the logistic regression functions; see Lemma 7[8] and Lemma 11 respectively. (ii)
Based on the sufficient condition, we give an upper bound for the sensitivity of every input point as well as bound the total sensitivity; see Lemma 23 and Lemma 25 respectively. (ii) Lastly, we combine the above with the coreset construction framework from Theorem 3 to obtain a provable sampling algorithm for coreset construction, as formally stated in Theorems 9-10. An important ingredient in this construction was an upper bound for the VC-dimension of the relevant query spaces. An upper bound of $O(d^2)$ for both functions is given in Section 4.

**Theorem 9.** Let $P$ be a set of $n$ points in the unit ball of $\mathbb{R}^d$, $\epsilon, \delta \in (0, 1)$, $k > 0$ be a sufficiently large constant, and let $t = (1 + k) \log n$. For every $p, x \in \mathbb{R}^d$, let $c_{\text{sigmoid}, k}(p, x) = \frac{1}{1 + e^{-px}} + \frac{\|x\|_2^2}{k}$. Finally, let $(Q, u)$ be the output of a call to MONOTONIC-CORESET($P, k, m$), where $m \in \Omega\left(\frac{1}{\epsilon^2} (d^2 \ln t + \ln \frac{1}{\delta})\right)$; see Algorithm 7. Then, with probability at least $1 - \delta$, $(Q, u)$ is an $\epsilon$-coreset for $(P, 1, \mathbb{R}^d, c_{\text{sigmoid}, k})$. Moreover, $|Q| \in O(m)$, and $(Q, u)$ can be computed in $O(nd + n \log n)$ time.

**Theorem 10.** Let $P$ be a set of $n$ points in the unit ball of $\mathbb{R}^d$, $\epsilon, \delta \in (0, 1)$, $R, k > 0$ where $k$ is a sufficiently large constant, and $t = R \log n(1 + Rk)$. For every $p \in \mathbb{R}^d, x \in B(0, R)$ let $c_{\text{logistic}, k}(p, x) = \log (1 + e^{p \cdot x}) + \frac{\|x\|_2^2}{k}$. Finally, let $(Q, u)$ be the output of a call to MONOTONIC-CORESET($P, k, m$) where $m \in \Omega\left(\frac{1}{\epsilon^2} (d^2 \ln t + \ln \frac{1}{\delta})\right)$; see Algorithm 7. Then, with probability at least $1 - \delta$, $(Q, u)$ is an $\epsilon$-coreset for $(P, 1, \mathbb{R}^d, c_{\text{logistic}, k})$. Moreover, $|Q| \in O(m)$ and $(Q, u)$ can be computed in $O(nd + n \log n)$ time.

**Supporting other activation functions.** The above theorems give two example activation functions that our framework supports. However, the framework is not limited to those activations only. To support other functions, one must prove the sufficient condition to obtain the sensitivity upper bound, which can be then simply plugged into Algorithm 1 to obtain the desired coreset.

6 Experiments

We implemented Algorithm 1 and, in this section, we evaluate its empirical results both on synthetic and real-world datasets. Rather than competing with existing solvers, our coreset is simply a preprocessing step which reduces the input size. To this end, we apply existing solvers as a black box on our small coreset. The results show that a coreset of size only 1% of the original data can represent the full data with an error $\epsilon$ smaller than 0.001. Open-source code can be found in 5.

**Competing methods.** Our main competing method is a random sampling scheme. As implied by the theoretical analysis, “important” points, i.e., with high sensitivity, are sampled with high probability in our coreset construction algorithm. However, such points are sampled with probability roughly $1/n$ using the naive uniform sampling. Hence, we expect the coreset would yield results much better than a uniform sampling scheme. With that said, we chose real-world databases with relatively uniform data, in order to demonstrate the effectiveness of our coreset even in such cases. Even in this case, the improvement over uniform sampling is consistent and usually significant.

**Datasets used.** We used the following datasets:

(i) **Synthetic dataset.** This data contains a set of $n = 20, 010$ points in $\mathbb{R}^2$. 20, 000 of the points were generated by sampling a two dimensional normal distribution with mean $\mu_1 = (10, 000, 10, 000)$ and covariance matrix $\Sigma_1 = \begin{pmatrix} 0.0025 & 0 \\ 0 & 0.0025 \end{pmatrix}$ and 10 points were generated by sampling a two dimensional normal distribution with mean $\mu_2 = (-9998, -9998)$ and covariance matrix $\Sigma_2 = \begin{pmatrix} 0.0025 & 0 \\ 0 & 0.0025 \end{pmatrix}$.

(ii) **Bank marketing dataset [27].** It contains $n = 20, 000$ numerical valued records in $d = 10$ dimensional space with. The data was generated for direct marketing campaigns of a Portuguese banking institution. Each record represents a marketing call to a client, that aims to convince him/her to buy a product (bank term deposit). A binary label (yes or no) was added to each record. We used the numerical values of the records to predict if a subscription was made.

(iii) **Wine Quality dataset [6, 38, 9, 21].** It contains $n = 6497$ numerical valued records in $d = 12$ dimensional space.

**Experiments.** We conducted the following experiments:

(i) **Sigmoid Activation.** For a given size $m$ we computed a coreset of size $m$ using Algorithm 1. We used the datasets above to produce coresets of size $5 \ln(n) \leq m \leq 20 \ln(n)$, where $n$ is the size of the full data, then we normalized the data and found the optimal solution to the problem with values of $k = 100, 500, 1000, 5000$ using the BFGS algorithm. We repeated the experiment with a uniform
sample of size $m$. For each optimal solution that we have found, we computed the sum of sigmoids and denoted these "approximated solutions" by $C_1$ and $C_2$ for our algorithm and uniform sampling respectively. The "ground truth" $C^k$ was computed using BFGS on the entire dataset. The empirical error is then defined to be $E_t = |\frac{C^k_t}{C^k} - 1|$ for $t = 1, 2$. For every size $m$ we computed $E_1$ and $E_2$ 100 times and calculated the mean of the results.

**(ii) Logistic Regression.** Similarly, we produced coresets and uniform samples of size $5 \ln(n) \leq m \leq 40 \ln(n)$ and maximized the regularized log-likelihood using the BFGS algorithm. For every sample size we calculated the negative test log-likelihood. Every experiment was repeated 20 times and the results were averaged. All the results are presented in Fig. 3.

![Graphs showing experimental results for different datasets and parameters.](image)

**(a) Bank Marketing dataset, $k = 100$**

**(b) Synthetic dataset, $k = 500$**

**(c) Wine dataset, $k = 1000$**

**(d) Bank Marketing dataset, $k = 10, R = 6$**

**(e) Wine dataset, $k = 500, R = 4$**

Figure 3: Experimental results. **Fig.3a-3c:** The error of maximizing sum of sigmoids using coreset and uniform sampling. **Fig.3d-3e:** Negative test log-likelihood. Lower is better in all figures.

**Discussion.** As seen in Fig. 3, our coreset outperforms the random sampling scheme as of accuracy, and is more stable (which can be seen in the standard deviation). For small sample sizes, the coreset provides a very small approximation error in practice, unlike the pessimistic theory which suggests bigger error. In this case, the coreset produces errors much smaller than the uniform sampling scheme. As the sample sizes grow, both the coreset and the random sample simply contain a big portion of the original full data, and hence their output errors decrease and also becomes more similar, as predicted. Furthermore, the coreset construction takes a neglectable amount of time from the total running time of computing a coreset and running the BFGS algorithm on the coreset. This is since the construction time is near linear. Hence, the computational time is not given in the graphs, as both sampling schemes required roughly the same total running time. Moreover, While in theory our results hold only for sufficiently large values of $k$, in practice we tested multiple $k$ values and witnessed a neglectable effect on the results. This is common in coresets paper where the worst-case theoretical bounds are too pessimistic and ignore structure in the data.

### 7 Conclusion

We provided a new coreset construction algorithm which computes a coreset for sums of sigmoid functions, which is common in deep learning and NP-hard to minimize, and logistic regression, where a coreset in [20] were suggested but with no support for regularization term, and no provable worst case bounds on the size of the coreset. Our construction algorithm is easily applicable to other functions as well. The coreset is of size near-logarithmic in the input size and can be computed in near-linear time.
Experimental results demonstrate that our coreset outperforms a standard sampling method, both in accuracy and stability. The experiments prove that empirically, our coreset is very effective; a coreset of size less than 1% of the input suffices to produce a small error of $\varepsilon = 0.001$. Future work includes generalizing for additional widely common functions, and hopefully relaxing the assumptions required on the handled functions.

A No Coreset for General Monotonic Functions

In this section, we provide the full proofs behind the impossibility bound claims presented in Section [3].

The following lemma proves that if the sensitivity of every input point is 1 in a given query space, then there is no non-trivial coreset for the query space.

**Lemma 11** (Lower bound via Total sensitivity). Let \((P, w, X, c)\) be a query space, and \(\varepsilon \in (0, 1)\). If every \(p \in P\) has sensitivity \(s_{P, w, X, c}(p) = 1\), then for every \(\varepsilon\)-coreset \((Q, u)\) we have \(Q = P\).

**Proof.** Let \((Q, u)\) be a weighted set, where \(Q \subset P\). It suffices to prove that \((Q, u)\) is not an \(\varepsilon\)-coreset for \(P\). Denote \(u_{\text{max}} \in \arg \max_{p \in Q} u(p)\), and \(u_{\text{min}} \in \arg \min_{p \in P} w(p)\).

Let \(p \in P \setminus Q\). By the assumption \(s_{P, w, X, c}(p) \geq 1\), there is \(x_p \in X\) such that

\[
\frac{w(p) c(p, x_p)}{C_P, w, x_p} = 1 > \frac{u_{\text{max}}}{u_{\text{min}}} - \frac{u_{\text{min}} (1 - \varepsilon)}{u_{\text{max}}}. \tag{1}
\]

Multiplication by \(C(P, w, x_p)\) yields

\[
\frac{w(p) c(p, x_p)}{u_{\text{max}}} > \frac{u_{\text{max}} - u_{\text{min}} (1 - \varepsilon)}{u_{\text{max}}} C(p, w, x_p). \tag{2}
\]

We have that

\[
C(Q, u, x_p) = \sum_{q \in Q} u(q) c(q, x_p)
\]

\[
= \frac{\sum_{q \in Q} u(q)}{w(q)} w(q) c(p, x_p) \leq \frac{u_{\text{max}}}{u_{\text{min}}} \sum_{q \in Q} w(q) c(q, x_p)
\]

\[
\leq \frac{u_{\text{max}}}{u_{\text{min}}} \sum_{p' \in P \setminus \{p\}} w(p) c(p', x_p)
\]

\[
= \frac{u_{\text{max}}}{u_{\text{min}}} (C(P, w, x_p) - w(p) c(p, x_p))
\]

\[
< \frac{u_{\text{max}}}{u_{\text{min}}} C(P, w, x_p) \left(1 - \frac{u_{\text{max}} - u_{\text{min}} (1 - \varepsilon)}{u_{\text{max}}} \right) \tag{3}
\]

\[
= (1 - \varepsilon) C(P, w, x_p),
\]

where \(\text{(2)}\) is by the assumption \(p \in P \setminus Q\), and \(\text{(3)}\) is by \(\text{(1)}\). Hence \(Q\) cannot be used to approximate \(C(P, w, x_p)\) and thus is not an \(\varepsilon\)-coreset for \(P\). \(\square\)

To prove there are query spaces \((P, w, X, c)\) which admit no non-trivial coreset, we are left to formally prove there exists a set of points for which the sensitivity of every point is 1. Together with the lemma above, this will complete the proof.

Similarly to the idea behind the counter example in Section [3], the idea behind finding a set for which every point has sensitivity 1 is to find a set of points in which every point is linearly separable from the rest of the set. Such a set was shown to exist in [20].

**Lemma 12** ([20]). There is a finite set of points \(P \subseteq \mathbb{R}^d\) such that for every \(p \in P\) and \(R > 0\) there is \(y_p \in \mathbb{R}^d\) of length \(\|y_p\| \leq R\) such that \(y_p \cdot p = -R\), and for every \(q \in P \setminus \{p\}\) we have \(y_p \cdot q \geq R\).

The following theorem stems from the combination of the above claims. Consider the query space \((P, w, X, c)\), where \(P\) is the set of points from the lemma above, and \(c(x, p) = f(x \cdot p)\) for every \(x, p \in \mathbb{R}^d\), where \(f : \mathbb{R} \to (0, \infty)\) is a non-decreasing monotonic function. The theorem proves that, with respect to the query space \((P, w, X, c)\), the sensitivity of every point in \(P\) is 1. We generalize a result from [20] by considering weighted data and by letting the cost be any function upholding the conditions of Theorem [15].
Theorem 13 (Theorem 4). Let \( f : \mathbb{R} \to (0, \infty) \) be a non-decreasing monotonic function that satisfies 
\[ \lim_{x \to \infty} \frac{f(-x)}{f(x)} = 0, \]
and let \( c(x, p) = f(x \cdot p) \) for every \( x, p \in \mathbb{R}^d \). Let \( \varepsilon \in (0, 1) \), \( n \geq 1 \) be an integer, and \( w : \mathbb{R}^d \to (0, \infty) \). There is a set \( P \subset \mathbb{R}^d \) of \( |P| = n \) points such that if \((Q, u)\) is an \( \varepsilon \)-coreset of \((P, w, \mathbb{R}^d, c)\) then \( Q = P \).

Proof. Let \( P \subset \mathbb{R}^d \) be the set that is defined in Lemma 12 and let \( p \in P \), and \( R > 0 \). By Lemma 12 there is \( y_p \in \mathbb{R}^d \) such that \( y_p \cdot p = -R \), and for every \( q \in P \setminus \{ p \} \) we have \( -y_p \cdot q \leq -R \). By this pair of properties,
\[ f(-y_p \cdot p) = f(R) \quad \text{and} \quad f(-y_p \cdot q) \leq f(-R), \]
where in the last inequality we use the assumption that \( f \) is non-decreasing. By letting \( x_p = -y_p \), we have
\[ \frac{w(q) f(x_p \cdot q)}{w(p) f(x_p \cdot p)} = \frac{w(q) f(-y_p \cdot q)}{w(p) f(-y_p \cdot p)} \leq \frac{w(q) f(-R)}{w(p) f(R)}. \]
Therefore, by letting \( w_{\max} \in \arg \max_{p \in P} w(p) \),
\[ s_{P, w, \mathbb{R}^d, c}(p) \geq \frac{w(p) f(x_p u \cdot p)}{\sum_{q \in P} w(q) f(x_p \cdot q)} = \frac{w(p) f(p \cdot x_p) + \sum_{q \in P \setminus \{ p \}} w(q) f(x_p \cdot q)}{1 + \sum_{q \in P \setminus \{ p \}} w(q) f(-R)} \geq \frac{1}{1 + (n - 1) \frac{w_{\max} f(-R)}{w(p) f(R)}}. \]
We also have
\[ \lim_{R \to \infty} \frac{w_{\max} f(-R)}{w(p) f(R)} = \frac{w_{\max}}{w(p)} \lim_{R \to \infty} \frac{f(-R)}{f(R)} = 0, \]
where the last derivation holds by the assumption on \( f \). Thus we obtain
\[ s_{P, w, \mathbb{R}^d, c}(p) = \sup_{R > 0} \frac{1}{1 + (n - 1) \frac{w_{\max} f(-R)}{w(p) f(R)}} = 1. \]
Theorem 13 then follows from the last equality and Lemma 11.

B \( \mathcal{L}_\infty \)-Coresets

Lemma 14 (Lemma 6). Let \( P \subset \mathbb{R}^d \) be a finite set, \( M, k > 0 \) be constants, \( f : \mathbb{R} \to (0, M] \) be non-decreasing function and \( g : [0, \infty) \to [0, \infty) \) be a function. For every \( x \in \mathbb{R}^d \) and \( p \in P \) define \( c_k(p, x) = f(p \cdot x) + \frac{g(||x||)}{k} \). Put \( p \in P \). Suppose there is \( b_p > 0 \) such that for every \( z \geq 0 \)
\[ f(||p|| z) + \frac{g(z)}{k} \leq b_p \left( f(-||p|| z) + \frac{g(z)}{k} \right). \]
Then \( \{ p \} \) is an \( \varepsilon \)-\( \mathcal{L}_\infty \)-coreset with \( \varepsilon = \frac{M}{f(0)} (b_p + 1) - 1 \), i.e., for every \( x \in \mathbb{R}^d \)
\[ \max_{p' \in P} c_k(p', x) \leq \frac{M}{f(0)} (b_p + 1) c_k(p, x). \]

Proof. Let \( x \in \mathbb{R}^d \) and \( q \in P \) such that \( x \cdot q > 0 \). We have, by the monotonic properties of \( f \),
\[ f(0) \leq f(x \cdot q). \]
Hence,
\[ \max_{p' \in P} f(x \cdot p') \leq M = \frac{M}{f(0)} f(0) \leq \frac{M}{f(0)} f(x \cdot q), \]
We now define \( P \), where (10) and (12) are by the Cauchy-Schwartz inequality and the monotonicity of \( f \), where the last inequality follows by the assumption \( b_p > 0 \). Case (ii): \( x \cdot p < 0 \). In this case \( x \cdot (-p) > 0 \). Substituting \( q = -p \) in (7) yields

\[
\max_{p' \in P} c_k(p', x) \leq \frac{M}{f(0)} \left( f(x \cdot p) + \frac{g(||x||)}{k} \right)
\]

where the last inequality follows by the assumption \( b_p > 0 \). Case (ii): \( x \cdot p < 0 \). In this case \( x \cdot (-p) > 0 \). Substituting \( q = -p \) in (7) yields

\[
\max_{p' \in P} c_k(p', x) \leq \frac{M}{f(0)} \left( f((x \cdot p) + \frac{g(||x||)}{k}) \right)
\]

where (10) and (12) are by the Cauchy-Schwartz inequality and the monotonicity of \( f \), and (11) follows by substituting \( z = ||x|| \) in the main assumption of the lemma.

**B.1 From \( \epsilon - \mathcal{L}_\infty \) coresets to \( \epsilon \)-coresets**

In what follows is the full proof for Lemma 15. We prove that the algorithm described in Section 4.2, which constructs a series of \( \mathcal{L}_\infty \) coresets, can indeed give an upper bound on the sensitivity of every input element as well as a near logarithmic upper bound on the total sensitivity.

**Lemma 15 (Lemma 7).** Let \( c : \mathbb{R}^d \times \mathbb{R}^d \to (0, \infty) \). Suppose that for some \( \epsilon \in (0, 1) \) there is a non-decreasing function \( \Delta_c(n) \) so that for any \( P' \subseteq \mathbb{R}^d \) of size \( n \) there is an \( \epsilon - \mathcal{L}_\infty \) coreset of size at most \( \Delta_c(n) \) for \((P', 1, \mathbb{R}^d, c)\). Then, for any \( P \subseteq \mathbb{R}^d \) of size \( n \) we can compute an upper bound \( s(p) \) on the sensitivity \( s_{P, 1, \mathbb{R}^d, c}(p) \) for each \( p \in P \), so that \( \sum_{P \in P} s_{P, 1, \mathbb{R}^d, c}(p) \leq (1 + \epsilon) \Delta_c(n) \ln n \).

**Proof.** The proof is constructive. We build a sequence of subsets \( P_i \supseteq P_2 \supseteq \cdots \supseteq P_m \), where \( P = P_1 \), \( m \leq n \), and \( |P_m| \leq \Delta_c(n) \). We construct the sequence as follows. If \( |P_i| \leq \Delta_c(n) \) the sequence stops. Otherwise, we compute a \( \mathcal{L}_\infty \) coreset \( C_i \) for \((P_i, 1, \mathbb{R}^d, c)\) of size \( |C_i| \leq \Delta_c(n) \). We now define \( P_{i+1} \subseteq P_i \setminus C_i \).

Put \( i \in [m] \). We now upper bound the sensitivity \( s_{P, 1, \mathbb{R}^d, c}(q) \) for every \( q \in C_i \) by \( \frac{1 + \epsilon}{\Delta_\mathcal{L}_\infty(n)} \) and upper bound the total sensitivity \( \sum_{P \in P} s(p) \leq (1 + \epsilon) \Delta_c(n) \ln n \).

Put \( x \in \mathbb{R} \) and \( q' \in C_i \), and consider \( 1 \leq j \leq i \). Let \( q_j \in C_j \) be the points in the \( \epsilon - \mathcal{L}_\infty \) coreset \( C_j \) such that \( c(q_j, x) = \max_{q \in C_j} c(q, x) = (1 + \epsilon) c(q_j, x) \). We now have that

\[
c(q', x) \leq \max_{p \in P_j} c(p, x) \leq (1 + \epsilon) \max_{q \in C_j} c(q, x) = (1 + \epsilon) c(q_j, x)
\]
where the first derivations holds since, by construction, \( q' \in P_j \). The second derivation is by the definition of an \( \varepsilon - \mathcal{L}_\infty \) coreset. We thus obtain that
\[
\frac{c(q', x)}{\sum_{p \in P} c(p, x)} \leq \frac{c(q', x)}{\sum_{i=1}^{\varepsilon \delta}(q_i, x)} \leq \frac{1 + \varepsilon}{i}, \tag{15}
\]
where the second derivation holds since \( \{q_j \mid 1 \leq j \leq i\} \subseteq P \), and the last derivation is by (14). Since (15) holds for any \( x \in \mathbb{R}^d \), we obtain that the sensitivity of \( q' \) is upper bounded by
\[
s_{P, 1, \mathbb{R}^d, c}(q') = \sup_{x \in \mathbb{R}^d} \frac{c(q', x)}{\sum_{p \in P} c(p, x)} \leq \frac{1 + \varepsilon}{i}.
\]
Hence, for every \( q' \in C_i \) we have that \( s_{P, 1, \mathbb{R}^d, c}(q') \leq \frac{1 + \varepsilon}{i} \). Now, the total sensitivity can be bounded by
\[
\sum_{p \in P} s_{P, 1, \mathbb{R}^d, c}(p) = \sum_{i=1}^{\varepsilon \delta}(1 + \varepsilon)(C_i) \leq \Delta_\varepsilon(n) \sum_{i=1}^{\varepsilon \delta} \frac{1 + \varepsilon}{i} \leq (1 + \varepsilon)\Delta_\varepsilon(n) \ln n.
\]

**B.2 Coreset sufficient condition**

In what follows we give the full proof for Theorem 8. The proof is constructive in the sense that it gives an upper bound for the sensitivity of every input point and upper bounds the total sensitivity by a term which is near logarithmic in the input size.

**Theorem 16 (Theorem 8).** Let \( M, k > 0 \) be constants, \( P \subseteq \mathbb{R}^d \) be a set of points, \( f : \mathbb{R} \to (0, M] \) be a monotonic non-decreasing function, and \( c_k(p', x) = f(\langle p' \cdot x \rangle) + \frac{g(\|x\|)}{k} \) for every \( x \in \mathbb{R}^d \) and \( p' \in P \). Suppose there is \( b : P \to (0, \infty) \) such that for every \( p \in P \) and every \( z > 0 \)
\[
f(\|p\| z) + \frac{g(z)}{k} \leq b(p) f(-\|p\| z) + \frac{g(z)}{k}.
\]

Let \( b_{\text{max}} \in \text{arg max}_{p \in P} b(p) \), \( t = (1 + \frac{M}{f(0)} b_{\text{max}}) \ln n \), and \( \varepsilon, \delta \in (0, 1) \). Lastly, let \( d_{\text{VC}} \) be the VC-dimension of \((P, 1, \mathbb{R}^d, c_k)\). Then, there is a weighted set \((Q, u)\), where \( Q \subseteq P \) and
\[
|Q| \in O \left( \frac{t^{\frac{1}{2}}}{\varepsilon^2} \left( d_{\text{VC}} \log t + \log \frac{1}{\delta} \right) \right),
\]
such that with probability at least \( 1 - \delta \), \((Q, u)\) is an \( \varepsilon \)-coreset for the query space \((P, 1, \mathbb{R}^d, c_k)\).

**Proof.** For \( p \in P \) we have that
\[
\max_{p' \in P} c_k(p', x) \leq \frac{M}{f(0)} (b + 1) c_k(p, x) \leq \frac{M}{f(0)} (b_{\text{max}} + 1) c_k(p, x).
\]

Where (17) is by substituting in Lemma 6 and (18) holds since for every \( p \in P \), \( b(p) \leq b_{\text{max}} \). Let \( \varepsilon(p) := \left( \frac{M}{f(0)} (b_p + 1) \right) - 1 \) for every \{p\} \( P \) and let \( \varepsilon = \left( \frac{M}{f(0)} (b_{\text{max}} + 1) \right) - 1 \). Thus, for every \( p \in P \), we have that \{p\} is an \( \varepsilon(p) \)-\( \mathcal{L}_\infty \) coreset which is an \( \varepsilon \)-\( \mathcal{L}_\infty \) coreset.

In Lemma 7 a sequence of distinct \( \mathcal{L}_\infty \) coresets that cover the entire set \( P \cap P \cap \cdots \cap P \subseteq P \) are constructed. For every \( p \in P \), let \( i(p) \) be the index of the \( \mathcal{L}_\infty \) coreset \( C_{i(p)} \) such that \( p \in C_{i(p)} \). Plugging \( \varepsilon \) and \( \Delta_\varepsilon(n) = 1 \) in Lemma 7 and its proof yields that we can upper bound the sensitivity of every \( p \in P \) by
\[
s_{P, 1, \mathbb{R}^d, c_k}(p) \leq \frac{1 + \varepsilon(p)}{i(p)} \leq \frac{1 + \varepsilon}{i(p)} = \left( \frac{M}{f(0)} (b_{\text{max}} + 1) \right).
\]
where \( i(p) \) is the index of \( p \) when sorting the points in \( P \) by their norm. Furthermore, the total sensitivity is bounded by

\[
t(P, 1, \mathbb{R}^d, c_k) = \sum_{p \in P} \left( \frac{M\left(\frac{f(0)}{f(0)} b_{\text{max}} + 1\right)}{i(p)} \right) \in O \left( (1 + \frac{M\left(\frac{f(0)}{f(0)} b_{\text{max}} + 1\right)}{f(0)} \ln n) \right).
\]

Observe that sensitivity of \( p \in P \) depends on \( \varepsilon(p) = \left[ \left( \frac{M}{f(0)} b(p) + 1 \right) - 1 \right] \) divided by the index \( i(p) \). Hence, empirically, to obtain smaller total sensitivity, we would prefer to reorder \( P \) such that points \( p \) with larger value of \( b(p) \) are divided by larger values \( i(p) \). Therefore, we can simply sort the points of \( P \) according to the values of the function \( b \), from smallest to largest. Thus, points \( p \) with larger value of \( b(p) \) are given larger index \( i(p) \).

Theorem 8 now immediately follows from Theorem 3. \( \square \)

C Main Proofs

In this section, we first prove a series of technical claims. We then utilize those claims to prove the main results of this work.

C.1 Technical Claims

**Lemma 17.** Let \( f : \mathbb{R} \rightarrow (0, \infty) \) be a monotonic increasing function such that \( f(0) > 0 \). Let \( c, k > 0 \). There is exactly one number \( x_{kc} > 0 \) that simultaneously satisfies the following claims.

(i) \( f \left( -\sqrt{ckx_{kc}} \right) = x_{kc}^2 \).

(ii) For every \( x > 0 \), if \( f \left( -\sqrt{ckx} \right) > x^2 \) then \( x < x_{kc} \).

(iii) For every \( x > 0 \), if \( f \left( -\sqrt{ckx} \right) < x^2 \) then \( x > x_{kc} \).

(iv) There is \( k_0 > 0 \) such that for every \( k' \geq k_0 \)

\[
\frac{1}{x_{kc}} \leq \sqrt{ck'}.
\]

**Proof.** Let \( g(x) = x^2 \). Define

\[
h_{kc}(x) = f(-\sqrt{ckx}) - g(x).
\]

(i): It holds that

\[
h_{kc}(0) = f(0)
\]

and

\[
h_{kc} \left( \sqrt{f(0) + 1} \right) < 0,
\]

where (21) holds since \( f \left( -\sqrt{ckx} \right) \leq f(0) \) for every \( x > 0 \), and \( g \left( \sqrt{f(0) + 1} \right) = f(0) + 1 \).

From (20) and (21) we have that \( 0 \in \left[ h_{kc} \left( \sqrt{f(0) + 1} \right), h_{kc}(0) \right] \). Using the Intermediate Value Theorem (Theorem 31) we have that there is \( x_1 \in \left( 0, \sqrt{f(0) + 1} \right) \) such that

\[
h_{kc}(x_1) = 0.
\]

We prove that \( x_1 \) is unique. By contradiction. Assume that there is \( x_2 \neq x_1 \) such that

\[
h_{kc}(x_1) = h_{kc}(x_2) = 0.
\]

16
Wlog assume that $x_1 < x_2$. By The Mean Value Theorem (Theorem 32), there is $r \in (x_1, x_2)$ such that

$$h_{kc}'(r) = \frac{h_{kc}(x_2) - h_{kc}(x_1)}{x_2 - x_1} = 0,$$

(24)

where (25) is by (23). The derivative of $h_{kc}$ is

$$h_{kc}'(x) = \left( f\left(-\sqrt{ck}x\right) - g(x) \right)' = -\sqrt{ck}f'\left(-\sqrt{ck}x\right) - g'(x) < 0,$$

(26)

(27)

where (26) is by (19) and (27) is since $f$ is monotonic increasing and thus $f'(x) > 0$ for every $x \in \mathbb{R}$ and $x, k, c > 0$. (27) is a contradiction to (25). Thus the Assumption (23) is false and $x_1$ is unique.

By (19) and (22)

$$f\left(-\sqrt{ck}x_1\right) = g(x_1).$$

(28)

By letting $x_{kc} = x_1$ and recalling that $g(x) = x^2$ we obtain

$$f\left(-\sqrt{ck}x_{kc}\right) = x_{kc}^2.$$

(29)

(ii): Let $x > 0$ such that $f\left(-\sqrt{ck}x\right) > x^2$. Plugging this and the definition $g(x) = x^2$ in (19) yields

$$h_{kc}(x) > 0.$$

(30)

We already proved that $h_{kc}'(x) < 0$ always. By the Inverse of Strictly Monotone Function Theorem (Theorem 33) we have that the inverse $h_{kc}^{-1}$ of $h_{kc}$ is a strictly monotone decreasing function. Applying $h_{kc}^{-1}$ on both sides of (29) gives

$$x < x_{kc}.$$

(31)

(iii): Let $x > 0$ such that $f\left(-\sqrt{ck}x\right) < x^2$. By this and by the definition of $g$ and (19) we have

$$h_{kc}(x) < 0.$$

(32)

We already proved that $h_{kc}'(x) < 0$ always. By the Inverse of Strictly Monotone Function Theorem (Theorem 33) we have that $h_{kc}$ has a strictly monotone decreasing inverse function $h_{kc}^{-1}$. Applying $h_{kc}^{-1}$ on both sides of (30) gives

$$x > x_{kc}.$$

(33)

(iv): We need to prove that there is $k_0$ such that for every $k' > k_0$ we have

$$x_{kc} \geq \frac{1}{\sqrt{ck'}}.$$

(34)

By contradiction, assume that for every $k' > 0$,

$$x_{kc} < \frac{1}{\sqrt{ck'}}.$$

(35)

Since $f$ is increasing and by (32) $-c\sqrt{ck}x_{kc} < -1$ we have that

$$f\left(-\sqrt{ck}x_{kc}\right) > f(-1).$$

(36)

where (33) holds since $f$ is increasing and by (32) $-c\sqrt{ck}x_{kc} < -1$. Since $\lim_{k \to \infty} \frac{1}{ck} = 0$, there is $k_0 > 0$ such that for every $k > k_0$

$$f(-1) > \frac{1}{ck} > x_{kc}^2.$$
where (34) is by (32). Plugging (34) in (35) yields
\[ f\left(-c\sqrt{k}x_{kc}\right) > x_{kc}^2. \] (35)

In contradiction to (i) Thus
\[ x_{kc} \geq \frac{1}{\sqrt{ck}} \] (36)

**Lemma 18.** Let \( f \) be either the sigmoid or the logistic regression function and let \( x_{1,1} > 0 \) which is obtained by applying Lemma 17 with \( f \) and \( k = c = 1 \). Then, For every \( x \geq 0 \)
\[ \frac{f(x) + x^2}{f(-x) + x^2} \leq \max \left\{ \frac{2}{2}, \frac{2}{x_{1,1}} \right\}. \]

**Proof.** Let \( x \geq 0 \). Substituting \( k = c = 1 \) in Lemma 17 yields that \( f(-x_{1,1}) = x_{1,1}^2 \). We show that \( \frac{f(x) + x^2}{f(-x) + x^2} \leq \max \left\{ \frac{2}{2}, \frac{2}{x_{1,1}} \right\} \) via the following case analysis. (i) \( f(x) \geq x^2 \) and \( f(-x) \geq x^2 \), (ii) \( f(x) \geq x^2 \) and \( f(-x) < x^2 \), (iii) \( f(x) < x^2 \) and \( f(-x) \geq x^2 \), and (iv) \( f(x) < x^2 \) and \( f(-x) < x^2 \).

**Case (i):** \( f(x) \geq x^2 \) and \( f(-x) \geq x^2 \). Since \( f(-x) \geq x^2 \), by substituting \( k = c = 1 \) in Lemma 17 we have that \( x \leq x_{1,1} \). Hence
\[ f(-x) + x^2 \geq f(-x) \geq f(-x_{1,1}) = x_{1,1}^2, \] (37) (38) (39)

where (37) is since \( x^2 > 0 \), (38) is since \( f \) is increasing and \( x \leq x_{1,1} \), and (39) is by definition of \( x_{1,1} \). By adding \( f(x) \) to both sides of the assumption \( f(x) \geq x^2 \) of Case (i) we obtain
\[ 2f(x) \geq f(x) + x^2. \] (40)

By (40) and (39) we obtain
\[ \frac{f(x) + x^2}{f(-x) + x^2} \leq \frac{2f(x)}{x_{1,1}^2} \leq \frac{2}{x_{1,1}^2} \leq \max \left\{ \frac{2}{2}, \frac{2}{x_{1,1}^2} \right\}. \] (41)

where the second inequality holds since \( f(x) \leq 1 \) due to \( f \) being the sigmoid function.

**Case (ii):** \( f(x) \geq x^2 \) and \( f(-x) < x^2 \). Since \( f(-x) < x^2 \), substituting \( k = c = 1 \) in Lemma 17 there is \( x_{1,1} \) such that
\[ f(-x) + x^2 \geq x_{1,1}^2, \] (42) (43)

where (42) is since \( f \) is a positive function and (43) is since \( x > x_{1,1} \). By adding \( f(x) \) to both sides of the assumption \( f(x) \geq x^2 \) of Case (ii) we have that
\[ f(x) + x^2 \leq 2f(x). \] (44)

By (44) and (43) we obtain
\[ \frac{f(x) + x^2}{f(-x) + x^2} \leq \frac{2f(x)}{x_{1,1}^2} \leq \frac{2}{x_{1,1}^2} \leq \max \left\{ \frac{2}{2}, \frac{2}{x_{1,1}^2} \right\}. \] (45)

where the second inequality holds since \( f(x) \leq 1 \) due to \( f \) being either the sigmoid or the logistic regression function.

**Case (iii):** \( f(x) < x^2 \) and \( f(-x) \geq x^2 \). By adding \( x^2 \) to both sides of the assumption \( f(x) < x^2 \) of Case (iii) we have that
\[ f(x) + x^2 \leq 2x^2. \] (46)
Furthermore, since \( f(-x) > 0 \) we have that
\[
  f(-x) + x^2 \geq x^2. 
\]  
Combining (46) and (47) we obtain
\[
  \frac{f(x) + x^2}{f(-x) + x^2} \leq 2 \frac{2x^2}{x^2} \leq 2 \leq \max \left\{ 2, \frac{2}{x_{1,1}} \right\}. 
\]  
Case (iv): \( f(x) < x^2 \) and \( f(-x) < x^2 \). By adding \( x^2 \) to both sides of the assumption \( f(x) < x^2 \) of Case (iv) we have that
\[
  f(x) + x^2 \leq 2x^2. 
\]  
Furthermore, since \( f(-x) \) for every positive \( z \) and for every \( D > 0 \) there is \( k \) such that
\[
  f(-x) \geq k \geq x. 
\]  
Combining (46) and (47) we obtain
\[
  \frac{f(x) + x^2}{f(-x) + x^2} \leq 2 \frac{2x^2}{x^2} \leq 2 \leq \max \left\{ 2, \frac{2}{x_{1,1}} \right\}. 
\]  
Combining the results of the case analysis: (41), (45), (48), and (51) we have that
\[
  \frac{f(x) + x^2}{f(-x) + x^2} \leq \max \left\{ 2, \frac{2}{x_{1,1}} \right\}. 
\]  
Lemma 19. Let \( f \) be the sigmoid function, let \( x_{1,1} \) be as in Lemma 18 and let \( c > 0 \). Assume that there is \( D > 1 \) such that \( \frac{f(cx)}{f(\sqrt{k})} \leq D \) for every \( y \geq 0 \) and \( k > 0 \). Then, there is \( k_0 > 0 \) such that for every \( k \geq k_0 \) and for every \( x \geq 0 \),
\[
  \frac{f(\sqrt{c}x) + \frac{x^2}{k}}{f(-\sqrt{c}x) + \frac{x^2}{k}} \leq 3D \max \left\{ 2, \frac{2}{x_{1,1}} \right\} ck. 
\]  
Proof. Let \( x \geq 0 \) and \( k, c > 0 \). We have that
\[
  f(cx) + \frac{x^2}{k} \leq D f \left( \frac{x}{\sqrt{k}} \right) + \frac{x^2}{k} \leq D \max \left\{ 2, \frac{2}{x_{1,1}} \right\} f \left( \frac{-x}{\sqrt{k}} \right) + \frac{x^2}{k}, 
\]  
where (53) holds since \( \frac{f(cx)}{f(\sqrt{k})} < D \) for every \( y \geq 0 \) and (54) holds since \( \frac{x^2}{k} \leq D \frac{x^2}{k} \), and since, by Lemma 18 for every positive \( z \) we have that
\[
  \frac{f(z) + z^2}{f(-z) + z^2} \leq \max \left\{ 2, \frac{2}{x_{1,1}} \right\}. 
\]  
Dividing (54) by \( f(-\sqrt{c}x) + \frac{x^2}{k} \) yields
\[
  \frac{f(cx) + \frac{x^2}{k}}{f(-\sqrt{c}x) + \frac{x^2}{k}} \leq D \max \left\{ 2, \frac{2}{x_{1,1}} \right\} \frac{f \left( \frac{-x}{\sqrt{k}} \right) + \frac{x^2}{k}}{f \left( \sqrt{c}x \right) + \frac{x^2}{k}}. 
\]  
We now proceed to bound \( R_{ck} = \frac{f \left( \frac{-z}{\sqrt{k}} \right) + \frac{x^2}{f \left( \sqrt{c}x \right) + \frac{x^2}{k}} \). By denoting \( z = \frac{x}{\sqrt{k}} \) we have that
\[
  R_{ck} = \frac{f \left( \frac{-z}{\sqrt{k}} \right) + \frac{x^2}{f \left( \sqrt{c}x \right) + \frac{x^2}{k}}. 
\]
We now compute an upper bound for $R_{ck}$ using the following case analysis: (i) $f(-z) \geq z^2$ and $f\left(-\sqrt{ck}z\right) \geq z^2$, (ii) $f(-z) < z^2$ and $f\left(-\sqrt{ck}z\right) < z^2$, (iii) and (iv) $f(-z) < z^2$ and $f\left(-\sqrt{ck}z\right) \geq z^2$. Let $z_{ck} > 0$ be such that $f\left(-\sqrt{ck}z_{ck}\right) = z_{ck}^2$ as given by Lemma 17(i). There are four cases

Case (i): $f(-z) \geq z^2$ and $f\left(-\sqrt{ck}z\right) \geq z^2$. Since $f\left(-\sqrt{ck}z\right) \geq z^2$, by Lemma 17(iii) we have that $z \leq z_{ck}$. Thus

$$f\left(-\sqrt{ck}z\right) \geq f\left(-\sqrt{ck}z_{ck}\right) = z_{ck}^2,$$

(57)

where (57) holds since $f$ is monotonic and $z \leq z_{ck}$, and (58) is from the definition of $z_{ck}$. Furthermore, by adding $f(-z)$ to both sides of the assumption $f(-z) \geq z^2$, we have that

$$f(-z) + z^2 \leq 2f(-z).$$

(59)

Substituting (59) and (58) in (56) yields

$$R_{ck} = \frac{f(-z) + z^2}{f\left(-\sqrt{ck}z\right) + z^2} \leq \frac{2f(-z)}{z_{ck}^2} \leq \frac{1}{z_{ck}^2},$$

(60)

where the last inequality is since $f(-z) \leq 1/2$ for every $z \geq 0$.

Case (ii): $f(-z) < z^2$ and $f\left(-\sqrt{ck}z\right) < z^2$. By adding $z^2$ to both sides of the assumption $f(-z) < z^2$, we have that

$$f(-z) + z^2 \leq 2z^2.$$  

(61)

Furthermore, since $f\left(-\sqrt{ck}z\right) > 0$ we have that

$$f\left(-\sqrt{ck}z\right) + z^2 \geq z^2.$$  

(62)

Combining (61) and (62) yields

$$R_{ck} = \frac{f(-z) + z^2}{f\left(-\sqrt{ck}z\right) + z^2} \leq \frac{2z^2}{z^2} = 2.$$  

(63)

Case (iii): $f(-z) \geq z^2$ and $f\left(-\sqrt{ck}z\right) < z^2$. Since $f\left(-\sqrt{ck}z\right) < z^2$, by Lemma 17 we have that $z > z_{ck}$. Thus

$$f\left(-\sqrt{ck}z\right) + z^2 \geq z^2 \geq z_{ck}^2.$$  

(64)

By adding $f(-z)$ to both sides of the assumption $f(-z) \geq z^2$, we have that

$$2f(-z) \geq f(-z) + z^2.$$  

(65)

Substituting (64) and (65) in (56) yields

$$R_{ck} = \frac{f(-z) + z^2}{f\left(-\sqrt{ck}z\right) + z^2} \leq \frac{2f(-z)}{z_{ck}^2} \leq \frac{1}{z_{ck}^2}.$$  

(66)

Case (iv): $f(-z) < z^2$ and $f\left(-\sqrt{ck}z\right) \geq z^2$. By adding $z^2$ to both sides of the assumption $f(-z) < z^2$, we have that

$$f(-z) + z^2 \leq 2z^2.$$  

(67)

Since $f\left(-\sqrt{ck}z\right) > 0$ we have that

$$f\left(-\sqrt{ck}z\right) + z^2 > z^2.$$  

(68)
Plugging (67) and (68) in (56) yields
\[
R_{ck} = \frac{f(-z) + z^2}{f(-\sqrt{ck}z) + z^2} \leq \frac{2z^2}{z^2} = 2. \tag{69}
\]
Combining the results of the case analysis: (60), (63), (66), and (69) we have that
\[
R_{ck} \leq 2 + \frac{1}{z_{ck}^2}. \tag{70}
\]
Furthermore, there exists \( k_0 > 0 \) such that for every \( k \geq k_0 \),
\[
\frac{1}{z_{ck}^2} \leq ck. \tag{71}
\]
Substituting (71) in (70) yields
\[
R_{ck} \leq 2 + ck, \tag{72}
\]
by (55) we have
\[
\frac{f(cx) + \frac{z^2}{k}}{f(-\sqrt{cx}) + \frac{z^2}{k}} \leq D \max \left\{ 2, \frac{2}{x_{1,1}^2} \right\} R_{ck}.
\]
Substituting (72) in the last term gives
\[
\frac{f(cx) + \frac{z^2}{k}}{f(-\sqrt{cx}) + \frac{z^2}{k}} \leq D \max \left\{ 2, \frac{2}{x_{1,1}^2} \right\} (2 + ck).
\]
It holds that for every \( k \geq \frac{1}{c} \) we have \( 2 \leq 2ck \) plugging this in the above term yields
\[
\frac{f(cx) + \frac{z^2}{k}}{f(-\sqrt{cx}) + \frac{z^2}{k}} \leq 3D \max \left\{ 2, \frac{2}{x_{1,1}^2} \right\} ck.
\]
\[\square\]

The following lemma is similar to Lemma 19 above, but for the logistic regression function. The proof is similar to the proof of Lemma 19.

**Lemma 20.** Let \( f \) be the logistic regression function, let \( x_{1,1} \) be as in Lemma 18 and let \( c, R > 0 \). Assume that there is \( D > 1 \) such that \( \frac{f(y)}{f\left(\frac{y}{c}\right)} \leq D \) for every \( y \geq 0 \) and \( k > 0 \). Then, there is \( k_0 > 0 \) such that for every \( k \geq k_0 \) and for every \( 0 \leq x \leq R, \)
\[
\frac{f(cx) + \frac{z^2}{k}}{f(-\sqrt{cx}) + \frac{z^2}{k}} \leq 3RD \max \left\{ 2, \frac{2}{x_{1,1}^2} \right\} ck.
\]

**Lemma 21.** Let \( f(x) = \frac{1}{1+e^{-x}} \) for every \( x \in \mathbb{R} \) and let \( c > 0 \). Then, there is \( k_0 > 0 \) such that for every \( k \geq k_0 \) and for every \( x \geq 0 \)
\[
\frac{f(cx) + \frac{z^2}{k}}{f(-cx) + \frac{z^2}{k}} \leq 6ck.
\]

**Proof.** It holds that \( f(0) > 0 \). Applying Lemma 17 with \( k = c = 1 \) yields \( x_{1,1} \) such that \( f(-x_{1,1}) = x_{1,1}^2 \). We now bound \( x_{1,1} \). Calculation shows that
\[
f\left(-\sqrt{\ln(1.2)}\right) > \left(\sqrt{\ln(1.2)}\right)^2.
\]
Plugging \( x = \sqrt{\ln(1.2)}, k = 1, c = 1 \) in Lemma 17 (iii) yields
\[
x_{1,1} \geq \sqrt{\ln(1.2)}. \tag{73}
\]

\[21\]
By applying Lemma 18 with $f$ we have
\[
\frac{f(x) + x^2}{f(-x) + x^2} \leq \max \left\{ 2, \frac{2}{x^2/1} \right\} \leq 11, \tag{74}
\]
where the last inequality is by (77).

Since $f(y) \leq 1$ for every $y > 0$ and $f \left( \frac{x}{\sqrt{k}} \right) \geq \frac{1}{2}$, for every $c, k > 0$ we have that
\[
\frac{f(cx)}{f \left( \frac{x}{\sqrt{k}} \right)} \leq 2. \tag{75}
\]
Applying Lemma 19 with $f, D = 2$ yields
\[
\frac{f(cx) + \frac{x^2}{k}}{f(-cx) + \frac{x^2}{k}} \leq 66kc. \tag{76}
\]

**Lemma 22.** Let $f = \log(1 + e^x)$ for every $x \in \mathbb{R}$ and let $c, R > 0$. Then, there is $k_0 > 0$ such that for every $k \geq k_0$ and for every $0 \leq x \leq R$
\[
\frac{f(cx) + \frac{x^2}{k}}{f(-cx) + \frac{x^2}{k}} \leq 3R \frac{\log (2e^{cR})}{\log(2)} kc. \tag{77}
\]

**Proof.** Let $0 \leq x \leq R$. Applying Lemma 17 with $k = c = 1$ yields $x_{1,1}$ such that $f(-x_{1,1}) = x_{1,1}^2$.
We now bound $x_{1,1}$. By simple calculations we have that
\[
f \left( -\sqrt{\ln(1.2)} \right) > \left( \sqrt{\ln(1.2)} \right)^2. \tag{78}
\]
Plugging $x = \sqrt{\ln(1.2)}, k = 1, c = 1$ in Lemma 17(ii) yields
\[
x_{1,1} \geq \sqrt{\ln(1.2)}. \tag{79}
\]
For every $c, k > 0$, since $x \leq R$ and $f$ is non-decreasing we have that
\[
f (cx) \leq f (cR), \tag{80}
\]
furthermore, since $x \geq 0$ and $f$ is increasing we have that
\[
f \left( \frac{x}{\sqrt{k}} \right) \geq \log(2). \tag{81}
\]
We have that
\[
\frac{f(cx)}{f \left( \frac{x}{\sqrt{k}} \right)} \leq \frac{f(cR)}{\log(2)} \tag{82}
\]
where (80) is by (78) and (79), (81) is by the definition of $f$ and (82) holds since $Rc > 0$. Applying Lemma 20 with $f, D = \frac{\log(2e^{cR})}{\log(2)}$ yields
\[
\frac{f(cx) + \frac{x^2}{k}}{f(-cx) + \frac{x^2}{k}} \leq 3R \frac{\log (2e^{cR})}{\log(2)} kc. \tag{83}
\]
C.2 Proofs of Our Main Claims

We start by proving the main claims with respect to the sigmoid activation function; see Lemma 23 and Theorem 24. We then prove the main claims for the logistic regression activation function; see Lemma 25 and Theorem 26.

**Lemma 23.** Let \( P = \{p_1, \ldots, p_n\} \subset \mathbb{R}^d \) be a set of points, sorted by their length. I.e. \( \|p_i\| \leq \|p_j\| \) for every \( 1 \leq i \leq j \leq n \). Let \( k > 0 \) be a sufficiently large constant and \( c_{\text{sigmoid}, k}(p, x) = \frac{1}{1 + e^{-p \cdot x}} + \frac{\|x\|^2}{k} \) for every \( x \in \mathbb{R}^d \) and \( p \in P \). Then the sensitivity of every \( p_j \in P \) is bounded by

\[
 s(p) = s_{P, 1, \mathbb{R}^d, c_{\text{sigmoid}, k}}(p) \in O \left( \frac{\|p_j\|}{k+1} \right),
\]

and the total sensitivity is

\[
 t = \sum_{p \in P} s(p) \in O \left( \log n + k \sum_{j=1}^{n} \frac{\|p_j\|}{j} \right).
\]

**Proof.** Define \( f(z) = \frac{1}{1 + e^{-z}} \) and \( g(z) = z^2 \) for every \( z \in \mathbb{R} \). Let \( x \in \mathbb{R}^d \), \( p_j \in P \) and \( i \in [1, j] \) be an integer. We substitute \( c = \|p_i\| \) in Lemma 23 to obtain that for every \( z > 0 \)

\[
 f(\|p_i\| z) + \frac{z^2}{k} \leq f(-\|p_i\| z) + \frac{z^2}{k} \leq 66\|p_i\| k.
\]

Denote \( b_{p_i} = 66\|p_i\| k \) and multiply the above term by \( f(-\|p_i\| z) + \frac{z^2}{k} \) to get

\[
 f(\|p_i\| z) + \frac{z^2}{k} \leq b_{p_i} \left( f(-\|p_i\| z) + \frac{z^2}{k} \right).
\]

Substituting in Lemma 6 \( p = p_i \), \( f(z) = \frac{1}{1 + e^{-z}} \), \( g(z) = z^2 \), \( M = 1 \), \( f(0) = \frac{1}{2} \) yields

\[
 \max_{p' \in P} c_{\text{sigmoid}, k}(p', x) \leq 2(2b_{p_i} + 1) c_{\text{sigmoid}, k}(p_i, x).
\]

Thus

\[
 c_{\text{sigmoid}, k}(p_j, x) \leq \max_{p' \in P} c_{\text{sigmoid}, k}(p', x) \leq 2(2b_{p_i} + 1) c_{\text{sigmoid}, k}(p_i, x),
\]

where \([92] \) is since \( p_j \in P \) and \([93] \) is by \([84] \). Dividing both sides by \( 2(2b_{p_i} + 1) \) yields

\[
 c_{\text{sigmoid}, k}(p_i, x) \geq \frac{c_{\text{sigmoid}, k}(p_j, x)}{2(b_{p_i} + 1)}.
\]

We now proceed to bound the sensitivity of \( p_j \). Since the set of points \( \{p_1, \ldots, p_j\} \) is a subset of \( P \), and since the cost function \( c_{\text{sigmoid}, k}(p_j, x) \) is positive we have that

\[
 \sum_{p' \in P} c_{\text{sigmoid}, k}(p', x) \geq \sum_{i=1}^{j} c_{\text{sigmoid}, k}(p_i, x).
\]

By summing \([94] \) over \( i \leq j \), we obtain

\[
 \sum_{i=1}^{j} c_{\text{sigmoid}, k}(p_i, x) \geq c_{\text{sigmoid}, k}(p_j, x) \sum_{i=1}^{j} \frac{1}{2(b_{p_i} + 1)}
\]

\[
 \geq c_{\text{sigmoid}, k}(p_j, x) \frac{j}{2(b_{p_j} + 1)},
\]

where the last inequality holds since \( b_{p_i} = 66\|p_i\| k \leq b_{p_j} \) for every \( i \leq j \). Combining \([95] \) and \([96] \) yields

\[
 \sum_{p' \in P} c_{\text{sigmoid}, k}(p', x) \geq \frac{j c_{\text{sigmoid}, k}(p_j, x)}{2(b_{p_j} + 1)}.
\]
Therefore, the sensitivity is bounded by
\[
sp,1,\mathbb{R}^d, c_{\text{sigmoid}, k}(p_j) = \sup_{x \in \mathbb{R}^d} \frac{c_{\text{sigmoid}, k}(p_j, x)}{\sum_{p' \in P} c_{\text{sigmoid}, k}(p', x)} 
\leq \frac{2(b_{p_j} + 1)}{j} \leq \frac{2(66 \|p_j\| k + 1)}{j}.
\]

Summing this sensitivity bounds the total sensitivity by
\[
\sum_{j=1}^{n} \frac{2(66 \|p_j\| k + 1)}{j} \in O \left( \log n + k \sum_{j=1}^{n} \frac{\|p_j\|}{j} \right).
\]

In what follows is the main claim and proof for the sigmoid activation function.

**Theorem 24 (Theorem 9).** Let \( P \) be a set of \( n \) points in the unit ball of \( \mathbb{R}^d \), \( \varepsilon, \delta \in (0, 1) \), and \( k > 0 \) be a sufficiently large constant. For every \( p, x \in \mathbb{R}^d \), let \( c_{\text{sigmoid}, k}(p, x) = \frac{1}{1 + e^{-x}} + \frac{\|x\|^2}{k} \). Finally, let \( (Q, u) \) be the output of a call to MONOTONIC-CORESET(\( P, \varepsilon, \delta, k \)); see Algorithm 1. Then, with probability at least \( 1 - \delta \), \( (Q, u) \) is an \( \varepsilon \)-coreset for \( (P, 1, \mathbb{R}^d, c_{\text{sigmoid}, k}) \). Moreover, for \( t = (1 + k)\log n \) we have \( |Q| \in O \left( \frac{1}{\varepsilon^2} (d \log t + \log \frac{1}{\delta}) \right) \), and \((Q, u)\) can be computed in \( O(dn + n \log n) \) time.

**Proof.** By [20], the dimension of \((P, w, \mathbb{R}^d, c)\) is at most \( d + 1 \), where \((P, w)\) is a weighted set, \( P \subseteq \mathbb{R}^d \), and \( c(p, x) = f(p \cdot x) \) for some monotonic and invertible function \( f \). By Lemma 23, the total sensitivity of \((P, 1, \mathbb{R}^d, c_{\text{sigmoid}, k})\) is bounded by
\[
t \in O \left( \log n + k \sum_{j=1}^{n} \frac{\|p_j\|}{j} \right) = O \left( \log n + k \sum_{j=1}^{n} \frac{1}{j} \right) = O \left( (1 + k) \log n \right),
\]
where the last equality holds since the input points are in the unit ball.

Plugging these upper bounds on the dimension and total sensitivity of the query space in Theorem 3 yields that a call to Algorithm 1 which samples points from \( P \) based on their sensitivity bound, returns the desired coreset \((Q, u)\). The running time is dominated by sorting the length of the points in \( O(n \log n) \) time after computing them in \( O(nd) \) time.

**Lemma 25.** Let \( P = \{p_1, \ldots, p_n\} \subseteq \mathbb{R}^d \) be a set of points, sorted by their length, i.e. \( \|p_i\| \leq \|p_j\| \) for every \( 1 \leq i \leq j \leq n \). Let \( R > 0, k > 0 \) be a sufficiently large constant and \( c_{\text{logistic}, k}(p, x) = \log(1 + e^{kx}) + \frac{\|x\|^2}{k} \) for every \( x \in B(0, R) \) and \( p \in P \). Denote by \( B(0, R) \) the ball of radius \( R \) centered at the origin. Then the sensitivity of every \( p_j \in P \) is bounded by \( s(p) = sp,1,B(0,R),c_{\text{logistic}, k}(p) \in O \left( \frac{R^2 \|p_j\|k + R^2}{j} \right) \), and the total sensitivity is
\[
t = \sum_{p \in P} s(p) \in O \left( R^2 \log n + R^3 k \sum_{j=1}^{n} \frac{\|p_j\|}{j} \right).
\]

**Proof.** Define \( f(z) = \log(1 + e^z) \) and \( g(z) = z^2 \) for every \( z \in \mathbb{R} \). Let \( x \in \mathbb{R}^d, p_j \in P \) and \( i \in [1, j] \) be an integer. We substitute \( c = \|p_i\| \) in Lemma 22 to obtain that for every \( z > 0 \)
\[
\frac{f(\|p_i\| x) + \frac{z^2}{k}}{f(-\|p_i\| x) + \frac{z^2}{k}} \leq 3R \frac{\log \left( 2e\|p_i\| R \right)}{\log(2)} \frac{1}{k} \|p_i\|.
\]
We now proceed to bound the sensitivity of $p$ where the last inequality holds since $p$ and (92) is since (91). Dividing both sides by $\frac{\log(1+e^R)}{\log(2)}$ yields

$$\max_{p' \in P} c_{\logistic,k}(p', x) \leq \frac{c_{\logistic,k}(p_j, x)}{\log(1+e^R)(b_{p_j} + 1)}.$$  

(91)

Thus

$$c_{\logistic,k}(p_j, x) \leq \frac{c_{\logistic,k}(p_j, x)}{\log(1+e^R)(b_{p_j} + 1)},$$

(92)

(93)

where (92) is since $p_j \in P$ and (93) is by (91). Dividing both sides by $\frac{\log(1+e^R)}{\log(2)}(b_{p_j} + 1)$ yields

$$c_{\logistic,k}(p_j, x) \geq \frac{c_{\logistic,k}(p_j, x)}{\log(1+e^R)(b_{p_j} + 1)}.$$  

(94)

We now proceed to bound the sensitivity of $p_j$. Since the set of points $\{p_1, \ldots, p_j\}$ is a subset of $P$, and since the cost function $c_{\logistic,k}(p_j, x)$ is positive we have that

$$\sum_{i=1}^{j} c_{\logistic,k}(p_i, x) \leq \sum_{i=1}^{j} c_{\logistic,k}(p_i, x).$$  

(95)

By summing (94) over $i \leq j$, we obtain

$$\sum_{i=1}^{j} c_{\logistic,k}(p_i, x) \geq \frac{j \log(2)}{\log(1+e^R)(b_{p_j} + 1)}.$$  

(96)

where the last inequality holds since $b_{p_i} = 3R\frac{\log(1+e^R)}{\log(2)} \| p_i \| k \leq b_{p_j}$ for every $i \leq j$. Combining (95) and (96) yields

$$\sum_{p' \in P} c_{\logistic,k}(p', x) \geq \frac{j \log(2)c_{\logistic,k}(p_j, x)}{\log(1+e^R)(b_{p_j} + 1)}.$$  

(97)

Therefore, the sensitivity is bounded by

$$s_{p,1,B(0,R),c_{\logistic,k}}(p_j) = \frac{\sup_{x \in B(0,R)} \sum_{p' \in P} c_{\logistic,k}(p_j, x)}{\log(1+e^R)(b_{p_j} + 1)} \leq \frac{\log(1+e^R)(b_{p_j} + 1)}{j \log(2)} \leq \frac{\log(1+e^R) \left( 3R\frac{\log(1+e^R)}{\log(2)} \| p_j \| k + 1 \right)}{j \log(2)}.$$  

25
Thus, \( s_{\mathcal{P},1,B(\mathbf{0},R),\text{c}_{\text{logistic},k}}(p_j) \in O\left( \frac{R^2 \|p_j\|^{k+R^2}}{j} \right) \). Summing this sensitivity bounds the total sensitivity by
\[
\sum_{j=1}^{n} \frac{R^3 \|p_j\|^{k+R^2}}{j} \in O\left( R^2 \log n + R^3 k \sum_{j=1}^{n} \frac{\|p_j\|}{j} \right).
\]

In what follows is the main claim and proof for the logistic regression function.

**Theorem 26 (Theorem [10])**. Let \( P \) be a set of \( n \) points in the unit ball of \( \mathbb{R}^d \), \( \varepsilon, \delta \in (0, 1) \), and \( R, k > 0 \) where \( k \) is a sufficiently large constant. For every \( p \in \mathbb{R}^d, x \in B(\mathbf{0}, R) \) let \( \text{c}_{\text{logistic},k}(p, x) = \log (1 + e^{p \cdot x}) + \frac{\|x\|^2}{k} \). Let \((Q,u)\) be the output of a call to MONOTONIC-CORESET\((P, \varepsilon, \delta, k)\). Moreover, for \( t = R \log n(1 + Rk) \), we have that \(|Q| \in O\left( \left( \frac{1}{2^d} \right) (d^2 \log t + \log \frac{1}{\delta}) \right) \) and \((Q,u)\) can be computed in \( O(dn + n \log n) \) time.

**Proof.** By [20], the dimension of \( (P,w,\mathbb{R}^d,c) \) is at most \( d + 1 \), where \( (P,w) \) is a weighted set, \( P \subseteq \mathbb{R}^d \), and \( c(p, x) = f(p \cdot x) \) for some monotonic and invertible function \( f \). By Lemma 25 the total sensitivity of \( (P,1,\mathbb{R}^d,\text{c}_{\text{logistic},k}) \) is bounded by
\[
t \in O\left( R^2 \log n + R^3 k \sum_{j=1}^{n} \frac{\|p_j\|}{j} \right) = O\left( R^2 \log n + R^3 k \sum_{j=1}^{n} \frac{1}{j} \right) = O\left( R^2 \log n(1 + Rk) \right),
\]
where the last equality holds since the input points are in the unit ball.

Plugging these upper bounds on the dimension and total sensitivity of the query space in Theorem 3 yields that a call to MONOTONIC-CORESET, which samples points from \( P \) based on their sensitivity bound, returns the desired coreset \((Q,u)\). The running time is dominated by sorting the length of the points in \( O(n \log n) \) time after computing them in \( O(nd) \) time. Sampling \( m = |Q| \) points from \( n \) points according to such a given distribution takes \( O(1) \) time after pre-processing of \( O(n) \) time. \( \square \)

## D Bounding the VC-dimension

In what follows we first give the formal definition of the VC dimension of a given query space. We then formally bound the VC dimensions of the sigmoid and logistic regression cost functions.

**Definition 27 (VC-dimension).** [12] [30] For a query space \((P,w,X,c)\) we define
\[
\text{range}(x,r) = \{ p \in P \mid w(p) c(p,x) \leq r \},
\]
for every \( x \in X \) and \( r \geq 0 \). The (VC) dimension of \((P,w,X,c)\) is the size \(|G|\) of the largest subset \( G \subseteq P \) such that have\n\[
|\{G \cap \text{range}(x,r) \mid x \in X, r \geq 0 \}| = 2^{|G|}.
\]

**Theorem 28 (Theorem 8.14 in [24] and generalized in [24])**. Let \( h \) be a function from \( \mathbb{R}^m \times \mathbb{R}^d \) to \( \{0, 1\} \), determining the class
\[
\mathcal{H} = \{ h_\theta(\cdot) : h_\theta : \mathcal{X} \to \mathbb{R}_{++}, \theta \in \mathbb{R}^m \}.
\]
Suppose that \( h \) can be computed by an algorithm that takes as input the pair \((\theta,x)\in \mathbb{R}^m \times \mathbb{R}^n\) and returns \( h_\theta(x) \) after no more than \( t \) of the following operations:

1. the arithmetic operations \(+,-,\times\) and \( / \) on real numbers,
2. jumps conditioned on \( >,\geq,\leq,=\) and \( \neq \) comparisons of real numbers, and
3. output 0, 1

26
and no more than \( p \) operations of the exponential function \( x \to e^x \) on real numbers, then the VC-dimension of \( \mathcal{H} \) is \( O(m^2p^2 + mp(t + \log(mp))) \).

**Lemma 29 (VC-dimension of the Sigmoid loss function).** Let \( k > 0 \) be a constant and \( (P, w, \mathbb{R}^d, c_{\text{sigmoid}, k}) \) be a query space where \( c_{\text{sigmoid}, k}(p, \mathbf{x}) = \frac{1}{1 + e^{p \mathbf{x}}} + \frac{\|\mathbf{x}\|^2}{k} \) for every \( \mathbf{x} \in \mathbb{R}^d \) and \( p \in P \). Then the VC-dimension of \( (P, w, \mathbb{R}^d, c_{\text{sigmoid}, k}) \) is at most \( O(d^2) \).

**Proof.** Observe that for every \( \mathbf{x} \in \mathbb{R}^d \) and \( p \in P \) we can evaluate \( c_{\text{sigmoid}, k}(p, \mathbf{x}) \) using \( t \in O(d) \) addition, multiplication, and division operations and \( p \in O(1) \) operations of the exponential function \( x \to e^x \). Then, by Theorem 28, the VC-dimension of \( (P, w, \mathbb{R}^d, c_{\text{sigmoid}, k}) \) is bounded by \( O(d^2) \). \( \square \)

**Lemma 30 (VC-dimension of the Logistic Regression loss function).** Let \( k > 0 \) be constants and \( (P, 1, \mathbb{R}^d, c_{\text{logistic}, k}) \) be a query space where \( c_{\text{logistic}, k}(p, \mathbf{x}) = \log(1 + e^{p \mathbf{x}}) + \frac{\|\mathbf{x}\|^2}{k} \) for every \( \mathbf{x} \in \mathbb{R}^d \) and \( p \in P \). Then the VC-dimension of \( (P, 1, \mathbb{R}^d, c) \) is at most \( O(d^2) \).

**Proof.** We first bound the VC-dimension of \( (P, 1, \mathbb{R}^d, g) \), where

\[
g(p, \mathbf{x}) = e^{c(p, \mathbf{x})} = (1 + e^{p \mathbf{x}}) e^{\frac{\|\mathbf{x}\|^2}{k}}.
\]

Observe that we can evaluate \( g(p, \mathbf{x}) \) using \( t \in O(d) \) addition, multiplication, and division operations and \( p \in O(1) \) operations of the exponential function \( x \to e^x \). Then, by Theorem 28, the VC-dimension of \( (P, 1, \mathbb{R}^d, g) \) is bounded by \( O(d^2) \).

We now show that the VC-dimension of \( (P, 1, \mathbb{R}^d, c) \) is upper bounded by the VC-dimension of \( (P, 1, \mathbb{R}^d, g) \). Recall that for the query space \( (P, 1, \mathbb{R}^d, c) \) and every \( \mathbf{x} \in \mathbb{R}^d \) and \( r \geq 0 \) we have that \( \text{range}(\mathbf{x}, r) = \{ p \in P \mid c(p, \mathbf{x}) \leq r \} \). For the query space \( (P, 1, \mathbb{R}^d, g) \) and every \( \mathbf{x} \in \mathbb{R}^d \) and \( r \geq 0 \) we have that \( \text{range}'(\mathbf{x}, r) = \{ p \in P \mid g(p, \mathbf{x}) \leq r \} \).

For every \( r \geq 0 \) let \( r_g := e^r \). Then we have that
\[
\text{range}(\mathbf{x}, r) = \{ p \in P \mid c(p, \mathbf{x}) \leq r \} = \{ p \in P \mid e^{c(p, \mathbf{x})} \leq e^r \} = \{ p \in P \mid g(p, \mathbf{x}) \leq r_g \} = \text{range}'(\mathbf{x}, r_g).
\]

Therefore, for every \( G \subseteq P \) we have that
\[
|\{ G \cap \text{range}(\mathbf{x}, r) \mid \mathbf{x} \in X, r \geq 0 \}| \leq |\{ G \cap \text{range}'(\mathbf{x}, r_g) \mid \mathbf{x} \in X, r_g \geq 0 \}|.
\]

Hence, by the definition of VC-dimension (see Definition 27), we have that the VC-dimension of the query space \( (P, 1, \mathbb{R}^d, c) \) is upper bounded by the VC-dimension of the query space \( (P, 1, \mathbb{R}^d, g) \) which is upper bounded by \( O(d^2) \). \( \square \)

## E Known results

For completeness, in what follows we formally state known claims, which were utilized in the proofs of the previous sections.

**Theorem 31 (Intermediate Value Theorem).** Let \( a, b \in \mathbb{R} \) such that \( a < b \) and let \( f : [a, b] \to \mathbb{R} \) be a continuous function. Then for every \( u \) such that
\[
\min \{ f(a), f(b) \} \leq u \leq \max \{ f(a), f(b) \},
\]
there is \( c \in (a, b) \) such that \( f(c) = u \).

**Theorem 32 (Mean Value Theorem).** Let \( a, b \in \mathbb{R} \) such that \( a < b \) and \( f : [a, b] \to \mathbb{R} \) a continuous function on the closed interval \([a, b]\) and differentiable on the open interval \((a, b)\). Then there is \( c \in (a, b) \) such that
\[
f'(c) = \frac{f(b) - f(a)}{b - a}.
\]

**Theorem 33 (Inverse of Strictly Monotone Function Theorem).** Let \( I \subseteq \mathbb{R} \). Let \( f : I \to \mathbb{R} \) be strictly monotone function. Let the image of \( f \) be \( J \). Then \( f \) has an inverse function \( f^{-1} \) and

- If \( f \) is strictly increasing then so is \( f^{-1} \).
- If \( f \) is strictly decreasing then so is \( f^{-1} \).
