Non-Abelian Localization for Supersymmetric
Yang-Mills-Chern-Simons Theories on Seifert Manifold

Abstract

We derive non-Abelian localization formulae for supersymmetric Yang-Mills-Chern-Simons theory with matters on a Seifert manifold \(M\), which is the three-dimensional space of a circle bundle over a two-dimensional Riemann surface \(\Sigma\), by using the cohomological approach introduced by Källén. We find that the partition function and the vev of the supersymmetric Wilson loop reduces to a finite dimensional integral and summation over classical flux configurations labeled by discrete integers. We also find the partition function reduces further to just a discrete sum over integers in some cases, and evaluate the supersymmetric index (Witten index) exactly on \(S^1 \times \Sigma\). The index completely agrees with the previous prediction from field theory and branes. We discuss a vacuum structure of the ABJM theory deduced from the localization.

1 Introduction

The localization theorem (Duistermaat-Heckman formula) \cite{1} (see also \cite{2}) reduces an integral over a symplectic manifold to a piecewise integral over isometry fixed locus. If the fixed locus is a set of isolated points, the integral reduces further to a discrete sum. This integral formula is so powerful and applied to various problems in mathematics and physics. In particular, in the last decade, the localization theorem has been utilized in physics for the evaluation of the volume of the symplectic moduli space \cite{3, 4, 5}, or the non-perturbative corrections to the supersymmetric gauge theories \cite{6}. More recently, the localization theorem is applied to the exact calculation of the partition function or vev of the Wilson loop in the supersymmetric gauge theories on a compact sphere \cite{7, 8} and leads the significant developments in both gauge and string theory.

The equivariant cohomology plays a key role in the proof of the localization theorem \cite{9}. The equivariant cohomology is constructed from the operator

\[ d_V = d + \iota_V, \]  

which is the sum of the exterior derivative \(d\) and the interior product \(\iota_V\) associated with the (Hamiltonian) vector field \(V\). \(d_V\) does not make a cohomology in a usual sense, since \(d_V\) is not nilpotent

\[ d_V^2 = \mathcal{L}_V, \]  

where \(\mathcal{L}_V\) is the Lie derivative along the vector field \(V\). However, if we restrict the differential forms, on which \(d_V\) is acting, to the invariant ones under the Lie derivative \(\mathcal{L}_V\), then the \(d_V\) becomes nilpotent and make a cohomology, which is called the equivariant cohomology. The localization theorem says that the integral on the symplectic manifold, which has the isometry generated by \(\mathcal{L}_V\), reduces on the fixed locus of the vector field.

It is known that the physical theories equipped with the supersymmetry is closely related to mathematical theory of the equivariant cohomology. Indeed, the square of the supercharge generates the sum of the possible symmetries in the supersymmetric theory, like the Poincaré (with dilatation if theory is superconformal), gauge and R-symmetry transformations. In this sense, we can identify the supercharges with the above \(d_V\). It
is also natural in physics to restrict the observables on the symmetry invariant ones, in particular the gauge invariant operators, as well as the construction of the equivariant cohomology. It is difficult in general to use all of symmetries for the equivariant cohomology and localization. So we have to reduce some of symmetries by choosing specific supercharges. This procedure is called the topological twisting and the constructed theory is called the topological field theory or cohomological field theory in the sense of the equivariant cohomology. The cohomological field theory remarkably develops itself and has brought about many benefits in physics and mathematics like the calculation of the topological invariants.

The other restriction of the supercharges occurs on the curved manifold. The (rigid) supersymmetry breaks in general on the curved manifold since the (global) Poincaré symmetry is broken. However, if there exist some isometries on the curved space, some supercharges, which is the Killing spinors associated with the isometry, may still remain. Then we can construct the equivariant cohomology by using at least one residual supercharge. If the square of the residual supercharge generates the isometry translation (Lie derivative) and gauge transformation, we can discuss the localization in the supersymmetric gauge theory for the isometry and gauge invariant states by using the equivariant cohomology. We can see clearly the meanings of the isometry fixed points and the role of the equivariant cohomology in the localization of the supersymmetric gauge theory.

On the other hand, in the discussion of the localization in three-dimensional supersymmetric Chern-Simons (CS) gauge theory with matters [8, 10] (see for review [11]), the supercharge used for the localization is chosen to be nilpotent itself (\(Q^2 = 0\)) while the supercharge in the cohomological field theory generates the isometry translation. Of course, the arguments of the localization by the nilpotent supercharge such as the 1-loop (WKB) exactness of the partition function is precise, and the results on the partition function and Wilson loops are exact, since their quantities are independent of the choice of the supercharge. The localization fixed locus can be also read from the supersymmetric transformations. There is nothing to lose in the nilpotent supercharge formulation of the localization in the supersymmetric gauge theory on the specific manifold like \(S^3\). However the formulation in [8] seems to relay on the specific metric on \(S^3\) although the CS theory is
essentially topological. For other kinds of manifold which have the same topology but different metric as $S^3$, the other discussions on the determinants of the harmonics are needed [12, 13, 14]. The nilpotent supercharge does not also explain why the supersymmetric Wilson loop along the isometry of the space is rather special in the localization.

The essential symmetry of the localization in the supersymmetric CS theory is the $U(1)$ isometry of the Hopf fibration of $S^3$. The Wilson line along the $U(1)$ isometry is special since it preserves the isometry. Källén recently has pointed out there is alternative choice of the supercharge which respects to the isometry of the manifold, and reformulate the localization in the supersymmetric CS theory on more general three-dimensional Seifert manifold $M$, which is a non-trivial circle bundle over a Riemann surface $\Sigma$ and possesses at least the $U(1)$ isometry [15]. In his formulation, the supercharge is not nilpotent but the square of the supercharge generates the Lie derivative along the isometry and the gauge transformation. In this sense, this formulation is very suitable for considering the relation to the equivariant cohomology. Indeed, the 1-loop determinants of the fields can be determined only by the topological nature (index theorem) in this formulation. This cohomological formulation also explains the exact partition function for the bosonic (non-supersymmetric) CS theory on the Seifert manifold [16, 17, 18, 19, 20] (see also for good reviews [21, 22]), as a consequence of the non-Abelian localization [23, 24].

In this paper, we follow Källén’s cohomological formulation of the localization in the supersymmetric CS theory on the Seifert manifold $M$ and generalize to include the matter multiplets giving in the ABJM theory [25, 26]. We construct the cohomological theory from the supersymmetry on $M$ by choosing a specific supercharge $Q$ (BRST charge) respecting the isometry. We more generally would like to consider Yang-Mills-Chern-Simons (YMCS) theory as displayed in the title, since dynamics of YMCS theory is perfectly interpreted by a brane configuration with $(p, q)5$-branes in Type IIB string theory [27, 28, 29, 30]. YMCS theory contains the Yang-Mills (YM) action, which is the kinetic terms of the gauge fields, in addition to the topological CS term. However, as we will see, the YM action is written as an exact form of the supercharge $Q$. The cohomological formulation says that the $Q$-exact action does not change the partition function or vev of the cohomological observables, that is, the partition function or vev of YMCS theory
is essentially equivalent to ones in theory with the CS terms alone. In this sense, we will just treat CS theory without the YM action, but the YM action plays the essential role when one evaluates the 1-loop determinants and derive the localization formula. So it makes sense to consider the YMCS theory though we are interested in the low energy (superconformal) CS theory, in the context of the cohomological field theory and localization arguments.

The paper is organized as follows:

In section 2, we briefly review some basics and formulae on the Seifert manifold. In this paper, we concentrate on a special Seifert manifold which is the circle bundle over the smooth Riemann surface (non-orbifolding case). So we explain the properties of the Seifert manifold for this restricted case. We successively construct the BRST transformations from the supercharges, which is compatible with the $U(1)$ isometry on the Seifert manifold. We also discuss the cohomological properties of the supersymmetric CS term and Wilson loop. They play important roles in the following discussions.

In section 3, we derive the localization formula for the vector multiplet by using the BRST transformations and cohomological observables. We can determines a general formula for the 1-loop determinants which dominates in the localization. In the cohomological field theory approach, the evaluation of the 1-loop determinants is simpler rather than the counting the spherical harmonics, since the determinants are essentially infinite products modes on the two-dimensional Riemann surface and Kaluza-Klein (KK) modes on the $S^1$ fiber. That is, CS theory on $M$ is equivalent to the two-dimensional (cohomological) YM theory \cite{31, 32} with the infinite number of the KK fields, and each number of zero modes can be determined by the index theorem (Hirzebruch-Riemann-Roch theorem) on $\Sigma$. Thus we can exactly evaluate the 1-loop determinants and localization formula for the supersymmetric CS theory on $M$. We find that there is no quantum level shift of the CS coupling in the supersymmetric CS theory without matter, in contrast with the bosonic CS theory, since the vector multiplet is ruled by the D-term which is a real object and the determinants do not admit phases. The exact partition function obtained by the localization also tells us various interesting informations on the vacuum structure of the CS theory. In particular, if we consider the partition function of the supersymmetric CS
theory on $S^1 \times \Sigma$, which is a special case of the Seifert manifold, we can evaluate the supersymmetric index (Witten index) of the system. It coincides with the known results from the field theory [33] and branes in string theory [30]. We also discuss the partition functions in the various limit of the degree of the fiber and the genus of $\Sigma$.

In section 4, we introduce matter chiral superfields in various representations. The matter superfields can get explicit mass or anomalous dimension for the superconformal theory. We find that the mass or anomalous dimension is embodied as the twisted boundary condition along the $S^1$ fiber. Then we can treat the matter superfields in the framework of the equivariant cohomology as well as the vector multiplet. The chiral superfields are ruled by complex F-terms. So the 1-loop determinants for the chiral superfields admit phases and may shift quantum mechanically the CS level. We can show the phases are cancelled out in the self-conjugate representations similar to the case on $S^3$. Finally we give the exact partition function for the ABJM theory (and its generalization) on the Seifert manifold and discuss the properties and the vacuum structures of it.

The last section is devoted to conclusion and discussion.

2 Cohomological Field Theory on Seifert Manifold

2.1 Basics of the Seifert manifold

We consider the supersymmetric YMCS theories on a three-dimensional manifold $M$, which is compact and orientable. The three-manifold $M$ admits a contact structure, which means that a three-form $\kappa \wedge d\kappa$ does not vanish anywhere on $M$. The 1-form $\kappa$ is called a contact form. The three-form $\kappa \wedge d\kappa$ plays an analogous role to a symplectic form on even dimensional manifold.

We also require that $M$ admits a free $U(1)$ action, that is, $M$ has a $U(1)$ isometry. In this case, $M$ can be represented by the total space of a circle ($S^1$) bundle over a Riemann surface $\Sigma$,

\[
S^1 \xrightarrow{p} M \xrightarrow{\pi} \Sigma,
\]

(2.1)
where we have determined that the degree of the bundle is $p$ and the genus (the number of handles) of the Riemann surface is $h$. The free $U(1)$ action obviously acts on the circle fiber. This kind of three-manifold is called a Seifert manifold.

Precisely speaking, Seifert manifolds are defined by more general principal $U(1)$-bundles over a Riemann surface with an orbifold, where there are some fixed points of the $U(1)$ action. We can extend the following results to the orbifold cases, but for simplicity of explanations and because of interests as physical models, we will take into account the non-orbifold case only in the following discussions.

The contact form $\kappa$ is associated with the circle fiber direction. Since $M$ has the $U(1)$ isometry, there exists a vector field $V$ along the circle direction. Then $\kappa$ and $V$ satisfy

$$\iota_V \kappa = 1,$$

(2.2)

where $\iota_V$ stands for the interior product with $V$. This means that the 1-form $\kappa$ is a base of $S^1$. We normalize $\kappa$ to be

$$\int_{S^1} \kappa = 2\pi \ell$$

(2.3)

where $\ell$ is the radius of the fiber $S^1$.

On the other hand, the base for a residual part of $M$ transverse to $\kappa$ contains in $d\kappa$, namely

$$d\kappa = \frac{p}{2\ell} \pi^* \omega,$$

(2.4)

where $p$ is the degree of the fiber bundle and $\pi^* \omega$ is the pullback of the symplectic (volume) form on the base Riemann surface $\Sigma$. The transversality between $\kappa$ and $d\kappa$ says $\iota_V d\kappa = 0$, namely combining with (2.2), we find

$$\mathcal{L}_V \kappa = 0,$$

(2.5)

where $\mathcal{L}_V \equiv d\iota_V + \iota_V d$ is the Lie derivative along $V$. Using the fact that the symplectic form on $\Sigma$ gives the area $\mathcal{A}$ of $\Sigma$

$$\int_{\Sigma} \omega = \mathcal{A},$$

(2.6)

the integral of $\kappa \wedge d\kappa$ over $M$ reduces to

$$\int_M \kappa \wedge d\kappa = \frac{p}{2\ell} \int_{S^1} \kappa \int_{\Sigma} \omega = p\pi \mathcal{A}.$$
In this sense, $\frac{\kappa}{2} \kappa \land d\kappa$ can be regarded as the volume form $\star 1$ on $M$. Here $\star$ is the Hodge star operator defined on $M$.

The metric also can be decomposed into a diagonal form

$$ds^2_M = \pi^* ds^2_\Sigma + \kappa \otimes \kappa,$$

(2.8)

where $\pi^* ds^2_\Sigma$ is the pullback of a conformally flat metric on $\Sigma$ with complex coordinates $(z, \bar{z})$

$$ds^2_\Sigma = \Omega dz \otimes d\bar{z}.$$  

(2.9)

So we can almost treat $M$ as the direct product of the Riemann surface $\Sigma$ and the $S^1$ fiber of the $\kappa$-direction. (Of course, since $\kappa$ is a function of points on $\Sigma$, $M$ is not the direct product.) This fact will be useful to construct supersymmetry on $M$.

Using the above properties, any 1-form (vector field) $A$ on $M$ can be decompose into

$$A = A_\Sigma + A_\kappa \kappa,$$

(2.10)

where $A_\kappa = \iota_V A$ is a scalar component along $\kappa$ and $A_\Sigma$ is a 1-form component horizontal to it. By definition, we find $\iota_V A_\Sigma = 0$, then $\iota_V dA_\Sigma = \mathcal{L}_V A_\Sigma$. More generally, any $n$-form $\Omega$ on $M$ is decomposed by using a projector $P \equiv \kappa \land \iota_V$

$$\Omega = (1 - P)\Omega + P\Omega.$$  

(2.11)

Thus $\iota_V \Omega$ is a $(n - 1)$-form component along the fiber direction. Similarly, the exterior derivative can be decomposed into

$$d = (1 - P) d + P d = \pi^* d_\Sigma + \kappa \land \iota_V d,$$

(2.12)

where $\pi^* d_\Sigma$ is the pullback of the exterior derivative on $\Sigma$. Using these definitions, one can see

$$A_\Sigma \land dA_\Sigma = A_\Sigma \land (\pi^* d_\Sigma A_\Sigma + \kappa \land \iota_V dA_\Sigma)$$

$$= A_\Sigma \land \kappa \land \mathcal{L}_V A_\Sigma.$$  

(2.13)

We will use these properties in the following sections.
Let us now construct supersymmetric gauge theories on the Seifert manifold $M$. Three-dimensional $\mathcal{N} = 2$ supersymmetric gauge theory, which has four supercharges and is obtained from a dimensional reduction from four-dimensional $\mathcal{N} = 1$ supersymmetric gauge theory with the gauge group $G$, contains a vector field $A_\mu$ ($\mu = 1, 2, 3$), two-component Majorana fermions (gauginos) $\lambda, \tilde{\lambda}$, a hermite scalar field in the adjoint representation $\sigma$, and an auxiliary field $D$. This field multiplet is called a vector multiplet. We can also include matter chiral superfields which are coupled with the vector multiplets, but we concentrate only on the theory of the vector multiplets (pure gauge theory) for a while. Three-dimensional supersymmetric gauge theories including matter multiplets will be discussed in the next section.

The supersymmetric YM action which is invariant under the supersymmetry on the curved manifold $M$ with a Euclidian signature metric is written in terms of the fields in the vector multiplets

$$S_{\text{SYM}} = \frac{1}{g^2} \int_M d^3 x \sqrt{g} \text{Tr} \left[ \frac{1}{2} F_{\mu\nu} F^{\mu\nu} + D_\mu \sigma D^\mu \sigma + \left( D + \frac{1}{\ell} \sigma \right)^2 \right.$$

$$+ i\bar{\lambda} \gamma^\mu D_\mu \lambda + i\bar{\lambda} [\sigma, \lambda] - \frac{1}{2\ell} \bar{\lambda} \lambda \left. \right] .$$ (2.14)

In three-dimensions, we can also include the supersymmetric CS term in the action

$$S_{\text{SCS}} = \frac{k}{4\pi} \int_M \text{Tr} \left[ A \wedge dA - \frac{2i}{3} A \wedge A \wedge A \right] + \frac{k}{4\pi} \int_M d^3 x \sqrt{g} \text{Tr} \left[ 2D\sigma - \bar{\lambda} \lambda \right],$$ (2.15)

which is invariant under the supersymmetric transformations. If we take into account the both actions $S_{\text{SYM}}$ and $S_{\text{SCS}}$ at the same time, the system is called supersymmetric YMCS theory. We discuss the exact partition function and dynamics of this system via the localization.

In general, the supersymmetry is violated due to the curvature of $M$. However, at least, one of the supersymmetries survives since $M$ has the $U(1)$ isometry after twisting the fields topologically. So if we choose suitably one of the supercharges, which respects the isometry, one can obtain the residual symmetry of the system.
Redefining the fields up to irrelevant overall constants and phases, we obtain the following transformations from the supersymmetry (see Appendix A)

\[
\begin{align*}
QA_z &= \lambda_z, \\
Q\bar{A}_\bar{z} &= \lambda_{\bar{z}}, \\
Q\kappa &= \eta, \\
Q\sigma &= i\eta, \\
QD &= 2i(D_\lambda A_\bar{z} - D_{\bar{z}} A_\lambda) - i[D_\kappa \chi_r - i[\sigma, \chi_r]] - \frac{i}{\ell}\eta, \\
Q\chi_r &= -2iF_{\bar{z}z} + D + \frac{1}{\ell}\sigma.
\end{align*}
\]  

(2.16)

This kind of the transformations is called the BRST transformations conventionally in topological field theory. Introducing a form notation on $M$, which is

\[
A = A_z dz + A_{\bar{z}} d\bar{z} + A_{\kappa} \kappa + A_{\sigma} \sigma
\]

and $\lambda = \lambda_z dz + \lambda_{\bar{z}} d\bar{z} + \eta\kappa$, we can rewrite the BRST transformations (2.16) compactly to

\[
\begin{align*}
QA &= \lambda, \\
Q\lambda &= -dA\sigma - i\nu V F, \\
Q\sigma &= i\eta, \\
QD &= 2i(D_\lambda A_{\bar{z}} - D_{\bar{z}} A_\lambda) - i(D_\kappa \chi_r - i[\sigma, \chi_r]) - \frac{i}{\ell}\eta, \\
Q\chi_r &= -2iF_{\bar{z}z} + D + \frac{1}{\ell}\sigma,
\end{align*}
\]

(2.17)

where $dA\sigma = d\sigma - i[A, \sigma]$ and $F = dA - iA \wedge A$ and $\frac{\kappa A F}{\kappa \wedge d\kappa}$ is the formal notation used in [23] with the normalization of the volume form $\ast 1 = \frac{\ell}{2}\kappa \wedge d\kappa$.

Furthermore, if we define a shift of the D-field by $Y_r \equiv -\frac{2i}{\ell} \frac{\kappa A F}{\kappa \wedge d\kappa} + D + \frac{1}{\ell}\sigma$, then we obtain

\[
\begin{align*}
QA &= \lambda, \\
Q\lambda &= -i(\nu V F - idA\sigma), \\
Q\sigma &= i\eta, \\
QY_r &= -i(\nu V dA\chi_r + [\sigma, \chi_r]), \\
Q\chi_r &= Y_r.
\end{align*}
\]

(2.18)

This simple transformation law becomes more interesting by introducing a combination of scalar fields in the adjoint representation

\[
\Phi \equiv A_\kappa + i\sigma.
\]

(2.19)

Noting that $\eta = \nu V \lambda$ and $QA_\kappa = \nu V (QA) = \eta$, we find immediately

\[
Q\Phi = 0.
\]

(2.20)

Using these notations, the BRST transformations are finally reduced to

\[
\begin{align*}
QA &= \lambda, \\
Q\lambda &= -i(\mathcal{L}_V - \delta_\Phi)A, \\
Q\Phi &= 0, \\
QY_r &= -i(\mathcal{L}_V - \delta_\Phi)\chi_r, \\
Q\chi_r &= Y_r.
\end{align*}
\]

(2.21)
where we have defined a gauge transformation by regarding formally $\Phi$ as a gauge parameter, that is,

$$\delta \Phi A = d_A \Phi = d_A A_\kappa + i d_A \sigma, \quad (2.22)$$

$$\delta \Phi \chi_r = i[\Phi, \chi_r] = i[A_\kappa, \chi_r] - [\sigma, \chi_r]. \quad (2.23)$$

Thus we find that the square of the transformations by $Q$ generates

$$Q^2 = -i(\mathcal{L}_V - \delta \Phi). \quad (2.24)$$

This property of the supercharge of our choice is important difference from the choice in [8], where the supercharge which is used for the localization satisfies $Q^2 = 0$. The cohomology in a usual sense is built from a nilpotent operator itself, namely $Q^2 = 0$, but if we restrict observables of the forms, on which $Q$ is acting, to ones invariant under the Lie derivative along $V$ (the $U(1)$ isometry) and the gauge transformations, the BRST transformation $Q$ becomes nilpotent on this restricted space. In other words, if we consider only the isometry and gauge invariant observables $O$ which satisfy

$$\mathcal{L}_V O = \delta \Phi O = 0, \quad (2.25)$$

the BRST transformations are nilpotent $Q^2 O = 0$ and $Q$ makes a cohomology on $O$. Similar to the usual cohomology, one should identify an element of the equivariant cohomology up to a $Q$-exact form

$$O \sim O + QO', \quad (2.26)$$

where $O$ satisfy $QO = 0$ but not $Q$-exact. This kind of the cohomology is called equivariant cohomology. The equivariant cohomology plays an essential role in the proof of the localization theorem.

From the equivariant cohomology point of view, we can understand true role of the supersymmetric CS action. First of all, we start from the bosonic (non-supersymmetric) CS action, which is

$$S_{CS}[A] = \frac{k}{4\pi} \int_M \text{Tr} \left[ A \wedge dA - \frac{2i}{3} A \wedge A \wedge A \right]. \quad (2.27)$$
Notice that this action is purely topological (independent of the metric on \( M \)) and invariant under the gauge transformations.

Now let us consider a shift of \( A \) by

\[
A \rightarrow A + i \sigma \kappa.
\]  
(2.28)

Recalling the definition of \( \Phi \) in (2.19), the shift of the gauge field is decomposed into

\[
A + i \sigma \kappa = A_\Sigma + A_\kappa \kappa + i \sigma \kappa = A_\Sigma + \Phi \kappa,
\]  
(2.29)

where \( A_\Sigma = A_z dz + A_{\bar{z}} d\bar{z} \) is a two-dimensional (horizontal) gauge field on \( \Sigma \). Substituting this shifted and decomposed gauge fields into the bosonic CS action (2.27), we find

\[
S_{CS}[A + i \sigma \kappa] = \frac{k}{4\pi} \int_M \text{Tr} \left[ A_\Sigma \wedge \kappa \wedge \mathcal{L}_V A_\Sigma + 2 \Phi \kappa \wedge F_\Sigma + \kappa \wedge d \kappa \Phi^2 \right],
\]  
(2.30)

where \( F_\Sigma = dA_\Sigma - i A_\Sigma \wedge A_\Sigma \) is a two-dimensional field strength on \( \Sigma \) and we have used \( A_\Sigma \wedge dA_\Sigma = A_\Sigma \wedge \kappa \wedge \mathcal{L}_V A_\Sigma \). The original bosonic CS action also has the same form as the above (2.30) by replacing \( \Phi \) by \( A_\kappa (\sigma = 0) \). However the inclusion of the additional scalar field \( \sigma \), which is contained in the vector superfield, complexifies \( A_\kappa \) to the complex adjoint scalar field \( \Phi \). Recalling the adjoint scalar \( \sigma \) originally comes from the dimensional reduction of one component of the four-dimensional gauge field, this complexification of \( A_\kappa \) means that the circle (\( S^1 \)) fiber bundle over \( \Sigma \), which we are considering, should be extend \( M \) with (dual of) \( \sigma \) to the holomorphic line bundle with the degree \( p \) over \( \Sigma \)

\[
L \xrightarrow{p} M',
\]  
(2.31)

where \( M' \) is now the four-dimensional manifold.

Secondary, we add a quadratic term of the fermions to the shifted bosonic CS action (2.30)

\[
S_{coh}[A, \sigma, \lambda] = S_{CS}[A + i \sigma \kappa] - \frac{k}{4\pi} \int_M \text{Tr} \left[ \kappa \wedge \lambda \wedge \lambda \right].
\]  
(2.32)

Then one can easily check

\[
QS_{coh}[A, \sigma, \lambda] = 0,
\]  
(2.33)
that is, the cohomological CS action $S_{\text{coh}}$ is an element of the equivariant cohomology. So $S_{\text{coh}}$ is a good physical observable in three-dimensional supersymmetric gauge theory on $M$ in this sense.

To see the relation between the cohomological CS action and the supersymmetric CS action, let us rewriting the cohomological CS action to separate the original bosonic CS action and the residual part including $\sigma$ and $\lambda$

$$S_{\text{coh}}[A, \sigma, \lambda] = S_{\text{CS}}[A] + \frac{k}{4\pi} \int_M \text{Tr} \left[ 2\sigma \left( i \frac{\kappa \wedge F}{\kappa \wedge d\kappa} - \frac{1}{2} \sigma \right) \kappa \wedge d\kappa - \kappa \wedge \lambda \wedge \lambda \right],$$  \hspace{1cm} (2.34)

where we have used the fact that

$$\kappa \wedge F = \kappa \wedge \{dA_\Sigma + (dA_\kappa) \kappa + A_\kappa d\kappa - i(A_\Sigma + A_\kappa \kappa) \wedge (A_\Sigma + A_\kappa \kappa)\}$$

$$= \kappa \wedge F_\Sigma + A_\kappa \kappa \wedge d\kappa. \hspace{1cm} (2.35)$$

Then we now add a BRST exact term into $S_{\text{coh}}$. We see it becomes the supersymmetric CS action (2.15)

$$S_{\text{SCS}}[A, \sigma, \lambda; Y_r, \chi_r] = S_{\text{coh}}[A, \sigma, \lambda] + Q \frac{k}{2\pi} \int_M d^3x \sqrt{g} \text{Tr}[\chi_r \sigma]$$

$$= S_{\text{CS}}[A] + \frac{k}{4\pi} \int_M \text{Tr} \left[ 2\sigma \left( i \frac{\kappa \wedge F}{\kappa \wedge d\kappa} - \frac{1}{2} \sigma + \frac{\ell}{2} Y_r \right) \kappa \wedge d\kappa \right.$$

$$\left. - \kappa \wedge \lambda \wedge \lambda - i\ell \chi_r \eta \kappa \wedge d\kappa \right]$$

$$= S_{\text{CS}}[A] + \frac{k}{4\pi} \int_M d^3x \sqrt{g} \text{Tr} \left[ 2D\sigma - \tilde{\lambda} \lambda \right], \hspace{1cm} (2.36)$$

where we have used the definition of $Y_r$. In summary, the difference between the cohomological CS action and the supersymmetric action is the $Q$-exact term, namely $S_{\text{coh}}$ and $S_{\text{SCS}}$ belong to the same equivariant cohomology class. Thus $S_{\text{SCS}}$ is supersymmetric ($Q$-closed) under the supercharge $Q$

$$QS_{\text{SCS}}[A, \sigma, \lambda; Y_r, \chi_r] = 0. \hspace{1cm} (2.37)$$

This fact says that the additional $Q$-exact term is irrelevant when we are considering a partition function with respect to $S_{\text{SCS}}$. We can replace $S_{\text{SCS}}$ with $S_{\text{coh}}$ in the path
integral without changing the value of the partition function or vev of the cohomological observable.

In a usual cohomological field theory, we can use any function of \( \Phi \)
\[
O_0 = \text{Tr} f(\Phi),
\]  
(2.38)
as a good 0-form cohomological observable, since it is \( Q \)-closed but not \( Q \)-exact. However, in our formulation, the above function (2.38) itself is not gauge invariant since \( \Phi \) includes a bare gauge field \( A_\kappa \). So (2.38) is not \( Q \)-cohomological observable in the supersymmetric CS theory. A possible \( Q \)-closed gauge invariant observable constructed from \( \Phi \) is the Wilson loop along the \( S^1 \) fiber
\[
W(C) \equiv \text{Tr} \mathcal{P} \exp i \oint_C \Phi \kappa = \text{Tr} \mathcal{P} \exp i \oint_C (A_\kappa + i\sigma)\kappa, 
\]  
(2.39)
where \( \text{Tr} \mathcal{P} \) is a trace over the representation \( R \) and \( \mathcal{P} \) represents a path ordered product along a loop \( C \), which is oriented to the \( U(1) \)-fiber direction. This Wilson loop observable is gauge invariant and does not violate the isometry along the \( U(1) \) fiber. So the BRST closed Wilson loop \( W(C) \) is a good physical observable in three-dimensional cohomological field theory on \( M \). Since \( W(C) \) is nothing but the supersymmetric Wilson loop, the \( Q \)-cohomological property of \( W(C) \) is a true reason why one can evaluate exactly the vev of \( W(C) \) in supersymmetric gauge theory on \( M \).

3 Exact Partition Function

3.1 Coupling independence

In this section, we derive the localization formula for the supersymmetric CS theory. A similar derivation is also discussed in [34] for the reduced supersymmetric matrix model. We borrow some useful notations from it in the following explanations.

So far, we have considered the supersymmetric CS action only. If we would like to treat the supersymmetric YMCS theory, we need to consider the supersymmetric YM action. The supersymmetric YM action can be written as an \( Q \)-exact form in general
\[
S_{\text{SYM}} = \frac{1}{g^2} Q \Xi, 
\]  
(3.1)
where $\Xi$ is a functional of fields, which is invariant under the gauge symmetry and the $U(1)$ isometry.

This $Q$-exactness of the supersymmetric YM action says that the partition function of the supersymmetric YM theory

$$Z = \int D\Psi e^{-S_{\text{SYM}}[\Psi]}, \quad (3.2)$$

is independent of the gauge coupling $g$, where $D\Psi$ is a path integral measure overall fields. In fact, if we once differentiate the partition function with respect to the gauge coupling, one can see

$$\frac{\partial Z}{\partial g} \propto \int D\Psi Q(\Xi e^{-S_{\text{SYM}}}) = 0, \quad (3.3)$$

since the path integral measure is made to be invariant under the $Q$-transformation. So we can evaluate the partition function (3.2) in any coupling region of $g$. In particular, we can exactly evaluate the partition function in the weak coupling region $g \to 0$. This means that a WKB (1-loop) approximation is exact in the evaluation of the partition function. This 1-loop exactness of the supersymmetric gauge theory is known also as the superrenormalizability in the perturbative expansion.

Similarly, we can show that the vev of the cohomological observable, which satisfies $Q O = 0$ but not $Q$-exact,

$$\langle O \rangle = Z^{-1} \int D\Psi O e^{-S_{\text{SYM}}}, \quad (3.4)$$

is also independent of the gauge coupling $g$. So one can evaluate the vev of $O$ exactly in the weak coupling limit. For example, the vev of the supersymmetric Wilson loop $W(C)$ can be evaluated exactly in the limit of $g \to 0$.

As we have seen in the previous section, the supersymmetric CS action itself is $Q$-cohomological observable. Then the supersymmetric YMCS theory can be regarded as an evaluation of the vev of the $Q$-cohomological CS action $O_{CS} = e^{iS_{CS}}$ in the supersymmetric YM theory. On the other hand, the terms containing the fermions in the cohomological CS action is quadratic. So we can integrate out the fermionic fields and obtain the purely bosonic (non-supersymmetric) CS theory (plus the adjoint scalar field). We can write
these relations schematically as follows

\[ Z_{CS+\sigma} = \int \mathcal{D}A \mathcal{D}\sigma e^{iS_{CS}[A+i\sigma]} \]

\[ = \int \mathcal{D}A \mathcal{D}\lambda e^{iS_{coh}[A,\sigma,\lambda]} = Z_{SCS} \]

\[ = \langle e^{iS_{SYM}} \rangle_{SYM} = Z_{SYMCS}, \quad (3.5) \]

by using the gauge coupling independence, where \( \langle \cdots \rangle_{SYM} \) stands for the vev in the supersymmetric YM theory. This is the reason why the partition functions of the supersymmetric YMCS theories are the same as those of the bosonic (non-supersymmetric) CS theories.

### 3.2 The localization

To proceed a proof of the localization theorem in the supersymmetric YM theory, we explicitly give the \( Q \)-exact action by

\[ S_{SYM} = \frac{1}{2g^2} Q \int_M \text{Tr} \left[ \bar{F}_v \wedge \ast Q F_v - i\ell \chi_r \mu_r \kappa \wedge d\kappa \right], \quad (3.6) \]

where \( \wedge \ast \) represents suitable norms among different degree of the field forms, including the inner product of the vector. We here combine the bosonic and fermionic fields into vectors \( \tilde{B}_v \equiv (A_\Sigma, \bar{\Phi}, Y_r) \) and \( \tilde{F}_v \equiv (\lambda_\Sigma, \eta, \chi_r) \), where \( \bar{\Phi} \equiv A_\kappa - i\sigma \). We have decomposed the form of fields into the components on the horizontal Riemann surface \( \Sigma \) and ones along the circle fiber. Since the adjoint scalar \( \Phi \) is \( Q \)-closed itself and does not have fermionic partner, we should treat this combination of fields rather special. \( \Phi \) will play an important role in the localization of the path integral. \( \mu_r \) in (3.6) defined by

\[ \mu_r \equiv \frac{\kappa \wedge F}{\kappa \wedge d\kappa} \quad (3.7) \]

corresponds to the D-term constraint in the supersymmetric YM theory. It is called the moment map (of the Kähler quotient space). Roughly speaking, the partition function

---

1 As we will see, there is a discrepancy in the CS level between the bosonic and supersymmetric theories. We have here ignored the quantum corrections (anomalies) from the integration of the chiral fermions.
of the YM theory on $M$ measures the volume of the flat connection moduli space on $M$
$\text{Vol}(\mathcal{M}_{F=0})$, where $\mathcal{M}_{F=0} = \mu_\tau^{-1}(0)/G$ is the Kähler quotient space.

In the above decomposition of the fields, the BRST transformations become

$$
QA = \lambda, \quad Q\lambda = -i(\mathcal{L}_V A - i[\Phi, A] - \pi_*d_\Sigma \Phi), \\
Q\Phi = 0, \quad Q\Phi = 2\eta, \quad Q\eta = -\frac{i}{2}(\mathcal{L}_V \Phi - i[\Phi, \Phi] - \mathcal{L}_V \Phi), \\
QY = -i(\mathcal{L}_V \chi - i[\Phi, \chi]), \quad Q\chi = Y,
$$

where $\pi_*d_\Sigma$ is the pullback of an exterior derivative restricted on $\Sigma$. $Q\overline{F}$ is regarded as
hermite conjugate of these transformations. Using these BRST transformations, we find
that the bosonic part of the above $Q$-exact action is

$$
S_{\text{SYM}}|_{\text{boson}} = \frac{1}{2g^2} \int_M \text{Tr} \left[ Q\overline{F} \wedge *QF - iY_r \mu_\tau \kappa \wedge d\kappa \right]
= \frac{1}{2g^2} \int_M \text{Tr} \left[ d_A \sigma \wedge *d_A \sigma + \iota_V F \wedge *\iota_V F + \frac{\ell}{2} Y_r (Y_r - 2i\mu_\tau) \kappa \wedge d\kappa \right].
$$

After integrating out the auxiliary field $Y_r$, the action reduces to

$$
S_{\text{SYM}}|_{\text{boson}} = \frac{1}{2g^2} \int_M \text{Tr} \left[ d_A \sigma \wedge *d_A \sigma + \iota_V F \wedge *\iota_V F + \frac{\ell}{2} \mu_\tau \kappa \wedge d\kappa \right]
= \frac{1}{2g^2} \int_M d^3x \sqrt{g} \text{Tr} \left[ \frac{1}{2} F_{\mu\nu} F^{\mu\nu} + \mathcal{D}_\mu \sigma^\nu \right].
$$

This is exactly the bosonic part of the supersymmetric YM action (2.14) obtained by
integrating out the auxiliary D-field. We can see the fermionic part of $S_{\text{SYM}}$ also agrees
with the supersymmetric YM one up to the field redefinitions defined in the previous
section.

Let us now discuss the meanings of the supersymmetric YM action (3.6). To make
clearer the role of each term in (3.6), we separate the terms by adding the extra parameter
$t_1$ and $t_2$

$$
S_{\text{SYM}} = \frac{1}{2g^2} Q \int_M \text{Tr} \left[ t_1 \left( \overline{F} \wedge *Q\overline{F} \right) - t_2 \left( 2i\chi_\tau \mu_\tau \kappa \wedge d\kappa \right) \right]
$$

Since both terms are still $Q$-exact independently, the partition function is independent of
the parameters $t_1$ and $t_2$. 

16
If we consider a situation that \( t_1 \ll t_2 \), the bosonic part proportional to \( t_2 \) gives a delta-functional constraint at \( \mu_r = 0 \). And also, the fermionic part will give suitable Jacobians for the constraint of \( \mu_r = 0 \). Thus the terms proportional to \( t_2 \) of the supersymmetric YM action give the D-term constraint \( \delta(\mu_r) \) with the suitable Jacobians in the path integral of the partition function.

In the other limit of \( t_1 \gg t_2 \), the bosonic part proportional to \( t_1 \) is essentially Gaussian of the field variables \( Q\mathcal{F}_v \). In the \( t_1 \to \infty \) limit, the Gaussian integral approximates to the delta-functional at \( Q\mathcal{F}_v = 0 \), namely the path integral is localized at the fixed point set of the BRST transformations \( Q\mathcal{F}_v = 0 \). This is the mechanism of the localization in the supersymmetric gauge theory. The fermionic part proportional to \( t_1 \) cancels out the \( t_1 \) dependence of the Gaussian integral of the bosonic part (and gives the fixed point at \( \mathcal{F}_v = 0 \)) since the degree of freedom of the bosonic and fermionic fields are the same. Both integral over the bosonic and fermionic fields give some Jacobians (1-loop) determinants into the path integral. We need to evaluate these Jacobians to obtain the localization formula.

In summary, the path integral localizes at the fixed points \( Q\mathcal{F}_v = 0 \) on the D-term constraint \( \mu_r = 0 \). Precisely speaking, the existence of \( \bar{\Phi} \), which complexifies the gauge transformation, relaxes the D-term constraint \( \mu_r = 0 \) to admit the higher critical points \( \mu_r \neq 0 \) [31]. It reflects the fact that the Kähler quotient by the gauge group \( \mu_r^{-1}(0)/G \) is equivalent to a quotient by the complexified gauge group \( G_C \) without the D-term (real moment map) constraint. The D-term constraint can not be imposed until the BF-type action \( S_{\text{BF}} = i \text{Tr} \int \Phi \mu_r \) is inserted. After integrating out \( \Phi \) completely, we get the localization on the quotient space of the flat connections \( \mathcal{M}_{F=0} \). However, for two dimensional YM theory or three dimensional CS theory, there exist the contributions from the higher critical points which contain not only \( \mu_r = 0 \) but also \( \mu_r \neq 0 \) because of the quadratic potential of \( \Phi \).

### 3.3 1-loop determinants

Now let us evaluate the Jacobians (1-loop determinants) precisely in the limit of \( t_1 \to \infty \), as follows. Similar arguments are discussed in [2] for the classical Hamiltonian system.
First of all, we expand the fields around the fixed point set by

\[
\mathcal{B}_v^I = \mathcal{B}_{v,0}^I + \frac{1}{\sqrt{t_1}} \tilde{\mathcal{B}}_v^I, \quad \mathcal{F}_v^I = 0 + \frac{1}{\sqrt{t_1}} \tilde{\mathcal{F}}_v^I,
\]

where \(\mathcal{B}_v^I\) and \(\mathcal{F}_v^I\) are each components of \(\tilde{\mathcal{B}}_v\) and \(\tilde{\mathcal{F}}_v\), and \(\mathcal{B}_{v,0}^I\) are solutions to \(Q\tilde{\mathcal{F}}_v = 0\).

Substituting this expansion into the Gaussian part of the supersymmetric YM action, it becomes

\[
S'_{\text{SYM}} = \frac{t_1}{2g^2} \int_M \text{Tr} \left[ Q\mathcal{F}_v^I \wedge \star Q\mathcal{F}_v^I - \mathcal{F}_v^I \wedge \star Q(Q\mathcal{F}_v^I) \right]
\]

\[
= \frac{1}{2g^2} \int_M \text{Tr} \left[ G_{IJ} \tilde{\mathcal{B}}_v^I \wedge \star \tilde{\mathcal{B}}_v^J + \frac{1}{2} \Omega_{IJ} \tilde{\mathcal{F}}_v^I \wedge \star \tilde{\mathcal{F}}_v^J \right] + O(1/t_1),
\]

where

\[
G_{IJ} = \frac{\delta^2}{\delta \tilde{\mathcal{B}}_v^I \delta \tilde{\mathcal{B}}_v^J} \left( Q\mathcal{F}_v^K \wedge \star Q\mathcal{F}_v^K \right) \bigg|_{\tilde{\mathcal{B}}_v = \tilde{\mathcal{B}}_{v,0}},
\]

\[
\Omega_{IJ} = \frac{\delta(Q\mathcal{F}_v^I)}{\delta \tilde{\mathcal{B}}_v^J} - \frac{\delta(Q\mathcal{F}_v^J)}{\delta \tilde{\mathcal{B}}_v^I} \bigg|_{\tilde{\mathcal{B}}_v = \tilde{\mathcal{B}}_{v,0}}.
\]

In the \(t_1 \to \infty\) limit, the Gaussian integrals of both bosonic and fermionic parts go to the delta-functionals

\[
\lim_{t_1 \to \infty} e^{-\frac{t_1}{2g^2} \int_M \text{Tr} Q\mathcal{F}_v^I \wedge \star Q\mathcal{F}_v^I} = \left( \frac{1}{\pi g^2} \right)^{-n_B/2} \frac{1}{\sqrt{\text{Det} |G_{IJ}|}} \delta(\tilde{\mathcal{B}}_v),
\]

\[
\lim_{t_1 \to \infty} e^{-\frac{t_1}{2g^2} \int_M \text{Tr} F_v^I \wedge \star Q(Q\mathcal{F}_v^I)} = \left( \frac{1}{g^2} \right)^{n_F/2} \sqrt{\text{Det} |\Omega_{IJ}|} \delta(\tilde{\mathcal{F}}_v),
\]

where the determinants are taken overall modes and representations of the fields, and \(n_B\) and \(n_F\) are the total number of the bosonic and fermionic modes, respectively. Combining these terms together, we obtain the exact result (up to irrelevant infinite constants which can be absorbed into the path integral measure)

\[
e^{-S'_{\text{SYM}}} = \sqrt{\frac{\text{Det} |\Omega_{IJ}|}{\text{Det} |G_{IJ}|}} \delta(Q\tilde{\mathcal{F}}_v) \delta(\tilde{\mathcal{F}}_v),
\]

which is independent of \(t_1\) and \(g\) as expected, since \(n_B = n_F\) because of the supersymmetry. Thus the path integral of the supersymmetric gauge theory has supports only on the fixed point set \(Q\tilde{\mathcal{F}}_v = \tilde{\mathcal{F}}_v = 0\) with the Jacobians.
Since the supersymmetric YM action is $Q$-exact, it is obviously satisfied that $QS'_\text{SYM} = 0$. This $Q$-closedness must be satisfied in any order of $t_1$ in the expansion (3.13). In particular, from the $Q$-closedness of the leading term in (3.13), we find that
\begin{equation}
G_{IK} \frac{\delta(QB^K_v)}{\delta F^I_v} = \Omega_{IK} \frac{\delta(QF^K_v)}{\delta B^I_v}.
\end{equation}
Then we get
\begin{equation}
\text{Det} |G_{IJ}| \text{Det} \left| \frac{\delta(QB^I_v)}{\delta F^J_v} \right| = \text{Det} |\Omega_{IJ}| \text{Det} \left| \frac{\delta(QF^I_v)}{\delta B^J_v} \right|,
\end{equation}
at $Q\bar{F}_v = \bar{F}_v = 0$. Substituting this into (3.18), we finally obtain
\begin{equation}
e^{-S'_\text{SYM}} = \sqrt{\text{Det} \left| \frac{\delta(QF^I_v)}{\delta B^J_v} \right| \delta(Q\bar{F}_v)(\bar{F}_v)}.
\end{equation}
Thus the Jacobians (1-loop determinants) are represented only in terms of the field differentials of the BRST transformations.

### 3.4 Fixed points and localization formula

We have seen that the path integral of the supersymmetric YM theory localizes at the fixed point equation $Q\bar{F}_v = 0$ of the BRST transformations. In order to solve this BRST fixed point equations more explicitly, we here decompose all fields in the adjoint representation as follows
\begin{equation}
\Psi = \sum_{a=1}^r \Psi^a H_a + \sum_{\alpha > 0} \Psi^\alpha E_\alpha + \sum_{\alpha > 0} \Psi^{-\alpha} E_{-\alpha},
\end{equation}
where $H_a$'s ($a = 1, \ldots, r = \text{rank } g$) are generators of the Cartan subalgebra of Lie algebra $g$ and $E_\alpha$ and $E_{-\alpha}$ are generators associated with the root $\alpha$. The generators satisfy the following relations
\begin{equation}
[H_a, H_b] = 0, \quad [H_a, E_\alpha] = \alpha_a E_\alpha,
\end{equation}
\begin{equation}
\text{Tr } E_\alpha E_\beta = \delta_{\alpha + \beta, 0}.
\end{equation}
\footnote{We can show the same relation from the Killing equation for the metric $G_{IJ}$.}
Since the supersymmetric YM theory has the non-Abelian gauge symmetry $G$, we need to fix the gauge. Firstly, we choose a gauge which "diagonalizes" $\Phi$ by setting $\Phi^\alpha = \Phi^{-\alpha} = 0$, namely

$$\Phi = \sum_{a=1}^r \Phi^a H_a,$$

(3.25)
in this gauge (but $\bar{\Phi}$ is not diagonalized). Under this choice of the gauge, there still remains Abelian gauge groups associated with the Cartan subalgebra. So we secondly require a gauge fix condition $\mathcal{L}_V A^a = 0$ for the Abelian part of the gauge fields. These gauge conditions fix all of the gauge symmetry of $G$ and induce additional functional determinants in the path integral from an action for ghosts $c$ and $\bar{c}:

$$S_{\text{ghost}}[c, \bar{c}] = \frac{1}{2g^2} \int_M d^3x \sqrt{|g|} \text{Tr} [c(\mathcal{L}_V \bar{c} - i [\Phi, \bar{c}])].$$

(3.26)

Using the above gauge fixing condition, the BRST fixed point equation $Q\bar{J}_v = 0$ says

$$\mathcal{L}_V - i \alpha(\Phi) A^\alpha_\Sigma = (\mathcal{L}_V + i \alpha(\Phi)) A^{-\alpha}_\Sigma = 0,$$

(3.27)

$$\mathcal{L}_V - i \alpha(\Phi) \Phi^\alpha_\Sigma = (\mathcal{L}_V + i \alpha(\Phi)) \Phi^{-\alpha}_\Sigma = 0,$$

(3.28)

d$\Phi = 0$,

(3.29)

$$Y_r = 0,$$

(3.30)

where $\alpha(\Phi) \equiv \sum_{a=1}^r \alpha_a \Phi^a$. The third line of the fixed point equations (3.29) means that $\Phi^a(x)$ is constant everywhere on $M$. We denote these constant zero modes by $\phi_a$ in the following.

After integrating out all off-diagonal components of the adjoint fields, including the ghosts, with taking care on the 1-loop determinants (3.21), we obtain the partition function of the Abelian gauge theory as a result of the localization

$$Z_{\text{SYM}} = \frac{1}{|W|} \int \prod_{a=1}^r \{ d\phi_a \mathcal{D}_a A^a_\Sigma \mathcal{D}_\lambda^a \} \prod_{\alpha \neq 0} \frac{\text{Det}_{c,\bar{c}} [\mathcal{L}_V - i \alpha(\phi)]}{\text{Det}_{A^a_\Sigma} [\mathcal{L}_V - i \alpha(\phi)]} \sqrt{\frac{\text{Det}_{c_r} [\mathcal{L}_V - i \alpha(\phi)]}{\text{Det}_\phi [\mathcal{L}_V - i \alpha(\phi)]}},$$

(3.31)

where $|W|$ is the order of the Weyl group of $G$, and we have assigned the field subscripts of the determinant in order to show which non-zero modes of the fields the determinant is taken over.
Since the number of modes of $\Phi$ and $\chi_r$ (0-forms) are the same, the determinants of $\Phi$ and $\chi_r$ are cancelled with each other. This reflects the fact that the D-term constraint is absorbed into the complexification of the gauge group by $\Phi$. The partition function becomes simply

$$Z_{SYM} = \frac{1}{|W|} \left| \int \prod_{a=1}^r \{d\phi_a D_A a^a D \lambda^a \} \prod_{\alpha \neq 0}^{\alpha} \frac{\text{Det}_{c,c} |L_V - i\alpha(\phi)|}{\text{Det}_{c} |L_V - i\alpha(\phi)|} \right|^2.$$

Note here that the determinants are definitely the absolute value, so there is no phases from the determinants, because of the hermiticity (no oscillatory nature) and the invariance under the parity symmetry, $\Phi \rightarrow -\Phi$ and $\Phi \rightarrow -\Phi$ of the supersymmetric YM action.

We now expand the fields on $M$ by

$$\Psi(z, \bar{z}, \theta) = \sum_{n \in \mathbb{Z}} \Psi_n(z, \bar{z}) e^{-in\theta/\ell},$$

where $\Psi_n(z, \bar{z})$, which satisfy $L_V \Psi_n = 0$, are functions on $\Sigma$ and we denote $\theta$ as the coordinate along the circle fiber direction. Then, for each $n$, the eigenvalue of $L_V$ on $\Psi_n$ is given by $-i\frac{n}{\ell}$, which means that $\Psi_n$ are sections of line bundles $O(-pn)$ over $\Sigma$. The difference of the number of those modes between 0-forms $(c, \bar{c})$ and 1-form $A_\Sigma$ on $\Sigma$ is given by the Hirzebruch-Riemann-Roch theorem

$$\dim \Omega^0(\Sigma, O(-pn) \otimes V_a) - \dim \Omega^1(\Sigma, O(-pn) \otimes V_a) = \frac{1}{2} \chi(\Sigma) - pn + \alpha(m),$$

where $\chi(\Sigma) = 2 - 2h$ is the Euler number of the Riemann surface. The second term comes from the first Chern class $c_1(O(-pn))$. The third term $\alpha(m) = \sum_{a=1}^r \alpha_a m_a$ is made from the first Chern class (magnetic flux) of the $a$-th background $U(1)$ gauge field on $\Sigma$, namely

$$m_a = \frac{i}{2\pi} \int_\Sigma F_a.$$

Using the above observations, the localization formula for the partition function reduces further to

$$Z_{SYM} = \frac{1}{|W|} \left| \int \prod_{a=1}^r \{d\phi_a D_A a^a D \lambda^a \} \prod_{n \in \mathbb{Z}} \prod_{\alpha \neq 0}^{\alpha} \left| \frac{n}{\ell} + \alpha(\phi) \right|^{\frac{1}{2} \chi(\Sigma) - pn + \alpha(m)} \right|^2.$$
We now evaluate the infinite product in the above integrand. We first see

\[
\prod_{n \in \mathbb{Z}, \alpha \neq 0} \left| \frac{n}{\ell} + \alpha(\phi) \right|^{\frac{1}{2} \chi(\Sigma) - p n + \alpha(m)} = \prod_{n \in \mathbb{Z}, \alpha > 0} \left( \frac{n}{\ell} + \alpha(\phi) \right)^{\chi(\Sigma)}
\]

\[
= \prod_{\alpha > 0} \alpha(\phi)^{\chi(\Sigma)} \prod_{n=1}^{\infty} \left( \frac{n^2}{\ell^2} \left( 1 - \frac{\ell^2 \alpha(\phi)^2}{n^2} \right) \right)^{\chi(\Sigma)}
\]

\[
= \prod_{\alpha > 0} (2 \sin \pi \ell \alpha(\phi))^{\chi(\Sigma)},
\]

(3.36)

where we have used the infinite product expansion of the sin-function

\[
\sin(\pi z) = \pi z \prod_{n=1}^{\infty} \left( 1 - \frac{z^2}{n^2} \right),
\]

(3.37)

and the zeta-function regularization of the infinite product

\[
\prod_{n=1}^{\infty} \frac{n^2}{\ell^2} = e^{-2c'(0) - 2c(0) \log \ell} = 2\pi \ell.
\]

(3.38)

Note that the dependence on the $U(1)$ gauge fields is disappeared from the determinant here.

We also would like to emphasis here that there is no phase coming from the infinite product of signs in particular. In the bosonic CS case, where the determinants are not the absolute value, the phase from the determinants is evaluated explicitly and leads to the famous quantum shift in the CS level $k \rightarrow k + \hat{c}_g$, where \( \hat{c}_g \) is the dual Coxeter number of \( \mathfrak{g} \). Our claim is that there is no level shift in the $\mathcal{N} = 2$ supersymmetric YMCS theory. This is consistent with the following physical consideration [35]: In the $\mathcal{N} = 2$ supersymmetric gauge theory, there are two chiral fermions \( \lambda, \tilde{\lambda} \) with the same chirality in the adjoint representation. These chiral fermions reproduce the CS action due to the parity anomaly in three-dimensions. Each chiral fermion contribute to the CS level by \( \pm \frac{1}{2} \hat{c}_g \), where the sign depends on the chirality of the fermions relative to the bare CS level. Then the total level shift in the $\mathcal{N} = 2$ supersymmetric CS theory is given by $k \rightarrow k + \hat{c}_g - \frac{1}{2} \hat{c}_g - \frac{1}{2} \hat{c}_g = k$, namely there is no quantum level shift. Incidentally, the quantum level shift in the $\mathcal{N} = 1$ and $\mathcal{N} = 3$ supersymmetric CS theory is $k \rightarrow k + \frac{1}{2} \hat{c}_g$ and $k \rightarrow k$, respectively.

Since YM part is $Q$-exact and coupling independent, it seems that the limit $g^2 \rightarrow \infty$ does not change the results and the YMCS theory is equivalent to pure CS theory with
free auxiliary gaugino in which the quantum level shift actually occurs [36]. One might think this conflicts with the above result. But as discussed in [37], since the limit of $g^2 \rightarrow \infty$ and the path integral for gaugino do not commute, the supersymmetric YMCS theory on the Seifert manifold does not receive the level shift in the contrast to pure CS theory. We will later calculate the supersymmetric indexes by the localization and see agreement with the results predicted by brane construction for supersymmetric YMCS theories. This confirm that no level shift occurs in our formulation.

Finally we obtain the localization formula for the supersymmetric YM theory on $M$

$$Z_{\text{SYM}} = \frac{1}{\ell^r |W|} \int_{-\infty}^{\infty} d\phi_a \prod_{\alpha > 0} \left( 2\sin \frac{\alpha(\phi)}{2} \right)^{\chi(\Sigma)} ,$$

where we have used the normalization of the volume of the Abelian gauge group $H = U(1)^r$ associated with the Cartan subalgebra

$$\frac{1}{(2\pi)^r} \int \prod_{a=1}^{r} DA_{\Sigma}^a D\lambda^a = \frac{\text{Vol}(H)}{(2\pi)^r} = 1,$$

and rescaled $2\pi \ell \phi_a \rightarrow \phi_a$ to be the integral over the dimensionless variables. The $U(1)$ integrals can be factored out since the integrand is independent of the background $U(1)$ fields.

### 3.5 The supersymmetric YMCS partition function

We arrived at the evaluation of the partition function of the supersymmetric YMCS theory at last. As we have explained above, the inclusion of the CS action does not change the localization fixed points and the derived 1-loop determinants since $e^{iS_{\text{CS}}}$ is the $Q$-closed cohomological observable. We should just evaluate $e^{iS_{\text{CS}}}$, or equivalently $e^{iS_{\text{coh}}}$ at the fixed points.

At the localization locus, the cohomological CS action reduces to

$$S_{\text{coh}}|_{\text{fixed points}} = k\ell \sum_{a=1}^{r} \int_{\Sigma} \text{Tr} \left[ \phi_a F_{\Sigma}^a + \frac{p}{4\ell} \phi_a^2 \omega - \frac{1}{2} \lambda^a \wedge \lambda^a \right] ,$$

where we have also used the gauge fixing condition $L_{\mathcal{V}} A^a = 0$. This action is exactly the same as the two-dimensional YM theory one (two-dimensional cohomological BF theory.
plus the mass term)! Thus we see that the supersymmetric YMCS theory on the Seifert manifold $M$ is almost the same as the supersymmetric (cohomological) YM theory on $\Sigma$ except for the 1-loop determinant (3.36). Using $\phi_a$ is constant on $\Sigma$ and $\lambda^a = 0$ at the fixed points, (3.41) reduces further to

$$S_{\text{coh}}|_{\text{fixed points}} = k \sum_{a=1}^r \left[ 2\pi \ell \phi_a m_a + \frac{pA}{4} \phi_a^2 \right], \quad (3.42)$$

with the $U(1)$-fluxes $m_a = \frac{1}{2\pi} \int_\Sigma F_a^\Sigma$.

Combining them together, we finally obtain the matrix model like integral formula for the partition function of the supersymmetric YMCS theory on $M$

$$Z_{\text{SYMCS}} = \frac{1}{(\ell)^r |W|} \sum_{\vec{m}} \int_\Sigma \prod_{a=1}^r \frac{d\phi_a}{2\pi} \prod_{a>0} \left( 2\sin \frac{\alpha(\phi)}{2} \right)^{\chi(\Sigma)} e^{ik \sum_{a=1}^r [\phi_a m_a + \frac{pA}{4\pi} \phi_a^2]}, \quad (3.43)$$

where we have rescaled $2\pi \ell \phi_a \to \phi_a$ and $\mu \equiv \frac{\pi A}{(2\pi \ell)^2}$ is a dimensionless parameter, which measures the ratio of the size of the base $\Sigma$ to the $S^1$ fiber. The summation of $\vec{m} = (m_1, m_2, \ldots, m_r)$ is taken over the topological sectors of the $U(1)$-fluxes admitted in this theory. On the Seifert manifold $M$, the first Chern class on $\Sigma$ is restricted in $\mathbb{Z}_p$, namely $m_a = 0, 1, \ldots, p-1$, since $H^2(M, \mathbb{Z}) = H^1(\Sigma, \mathbb{Z}) \oplus \mathbb{Z}_p$. This integral expression agrees with the CS matrix integral on $S^3$ [19, 20] by changing the integral contour.

Let us investigate the matrix integral (3.43) further. If we consider the limit of $p \to \infty$ with $p \mu$ fixed, the summation over $\vec{m}$ is unrestricted. Using the Poisson resummation of the periodic delta function

$$\frac{1}{(2\pi)^r} \sum_{\vec{m} \in \mathbb{Z}^r} \prod_{a=1}^r e^{ik \phi_a m_a} = \frac{1}{k^r} \sum_{\vec{n} \in \mathbb{Z}^r} \prod_{a=1}^r \delta \left( \phi_a - \frac{2\pi n_a}{k} \right), \quad (3.44)$$

we can integrate out $\phi_a$’s in (3.43) explicitly, then the partition function of the supersymmetric YMCS is expressed in terms of the summation only over the discrete integer set

$$Z_{\text{SYMCS}} = \frac{1}{(\ell)^r |W|} \sum_{\vec{n} \in \mathbb{Z}^r} \prod_{a>0} \left( 2\sin \frac{\pi}{k} \alpha(n) \right)^{\chi(\Sigma)} e^{i\pi \mu \sum_{a=1}^r n_a^2}, \quad (3.45)$$

where $\alpha(n) = \sum_{a=1}^r \alpha_a n_a$. 

24
This partition function is exactly the same as the $q$-deformed two-dimensional YM theory one \cite{38} by the identification
\[ g_s \equiv -\frac{2\pi i}{k}. \] (3.46)

To see this more explicitly, we consider the case of $G = U(N)$ in the following. The partition function becomes
\[ Z_{\text{SYMCS}} = C_N \sum_{n_1 > \cdots > n_N} \prod_{1 \leq a < b \leq N} [n_a - n_b]_{q}^{\chi(\Sigma)} q^{\frac{1}{2}p\mu \Sigma a=1 n_a^2}, \] (3.47)
where \( C_N \equiv e^{i \pi \chi(\Sigma) N(N-1)} (\frac{2\pi i}{k})^N \) and \([x]_q\) is the $q$-number
\[ [x]_q \equiv q^{x/2} - q^{-x/2}, \] (3.48)
with \( q \equiv e^{-g_s} = e^{\frac{2\pi i}{k}} \). Here we have replaced the sum over the integer set \( n_a \in \mathbb{Z}^N \) with a non-colliding integer set \( n_1 > n_2 > \cdots > n_N \) with a fixed order using the Weyl group, since \([n_a - n_b]_q\) vanishes and drops from the sum of the partition function if \( n_a = n_b \).

These non-colliding integer set can be also expressed by the ordered colliding integer set \( \nu_1 \geq \nu_2 \geq \cdots \geq \nu_N \) through
\[ n_a \equiv \nu_a - a + \frac{N + 1}{2}, \] (3.49)
that is, \( \nu_a \) can be identified with the number of $a$-th row of the Young diagram. Then the summation over \( n_a \) is equivalent to the summation over the representation $R$ associated with the Young diagram $Y = (\nu_1, \nu_2, \ldots, \nu_N)$. Thus we obtain
\[ \frac{Z_{\text{SYMCS}}}{Z_0} = \sum_R (\dim_q R)^{\chi(\Sigma)} q^{\frac{1}{2}p\mu C_2(R)}, \] (3.50)
where
\[ \dim_q R = \prod_{1 \leq a < b \leq N} \frac{[\nu_a - \nu_b + b - a]_q}{[b - a]_q}, \] (3.51)
is the quantum dimension of the representation $R$ and
\[ C_2(R) = \kappa_R + N|R|, \] (3.52)
is the quadratic Casimir in the representation \( R \) with \( \kappa_R \equiv \sum_{a=1}^{N} \nu_a(\nu_a - 2a + 1) \) and \( |R| \equiv \sum_{a=1}^{N} \nu_a \).

Here \( Z_0 \) is the contribution to the partition function from the lowest critical point ("ground state")

\[
Z_0 = C_N \prod_{1 \leq a < b \leq N} [b - a]_{\chi^2} q^{N(N^2 - 1)/24},
\]

where the Young diagram is empty or \( n_a \) belongs to the Weyl vector of \( SU(N) \), namely \( n_a = \rho_a = N + 1 - a \). \( Z_0 \) is essentially the partition function of the purely bosonic CS theory on \( M \) without the quantum level shift up to some overall constants. We discuss a meaning of the choice of various partitions next.

### 3.6 The supersymmetric index

The other case where we can use the resummation formula is the \( p = 0 \) case, namely \( M \) is the direct product \( M = S^1 \times \Sigma \). In this case, there is no torsion \( M \) and the second cohomology on \( \Sigma \) is not restricted, then \( H^2(\Sigma, \mathbb{Z}) = \mathbb{Z} \). Using the periodic delta function \([3.44]\), the partition function of the \( U(N) \) gauge theory can be evaluated by

\[
Z_{SYMCS}(S^1 \times \Sigma) = C_N \sum_{n_1 > \cdots > n_N} \prod_{1 \leq a < b \leq N} [n_a - n_b]_{\chi^2} q^{\frac{N(N^2 - 1)}{24}},
\]

which could be called the partition function of the \( q \)-deformed two-dimensional BF theory on \( \Sigma \).

The summation here is taken over the ordered non-colliding integer set, but we must be careful \( q \) is at the root of unity \( e^{\frac{2\pi i}{k}} \) in the CS theory. Then the \( q \)-number \( ([x]_q)_{\chi^2} \) for even \( \chi(\Sigma) \) becomes periodic (sine-function) and invariant under the shift \( x \to x + ks \) \((s \in \mathbb{Z})\). So if we define

\[
n_a = ks_a + \tilde{n}_a,
\]

where \( s_a \in \mathbb{Z} \) and \( \tilde{n}_a = 0, 1, \ldots, k - 1 \), which are chosen to satisfy \( n_1 > n_2 > \cdots > n_N \), then the partition function is written in terms of the summation over the fundamental domain of \( \tilde{n}_a \)

\[
Z_{SYMCS}(S^1 \times \Sigma) = \tilde{C}_N \sum_{\tilde{n}_1 > \cdots > \tilde{n}_N} \prod_{1 \leq a < b \leq N} [\tilde{n}_a - \tilde{n}_b]_{\chi^2} q^{\frac{N(N^2 - 1)}{24}},
\]

where the Young diagram is empty or \( n_a \) belongs to the Weyl vector of \( SU(N) \), namely \( n_a = \rho_a = N + 1 - a \). \( Z_0 \) is essentially the partition function of the purely bosonic CS theory on \( M \) without the quantum level shift up to some overall constants. We discuss a meaning of the choice of various partitions next.
where the constant $\tilde{C}_N \equiv C_N \left( \frac{1}{N!} \sum_{\tilde{s} \in \mathbb{Z}^N} 1 \right)$ is regularized by the zeta function for example.

Note that there is no choice of the summation and the partition function vanishes if $N > k$, since the summation is taken over $N$ integers $\tilde{n}_a$, which are chosen within the integers from 0 to $k - 1$ with the non-colliding order $\tilde{n}_1 > \cdots > \tilde{n}_N$. This fact strongly suggests that the supersymmetric index (Witten index)

$$I = \text{Tr}(-1)^F$$

(3.57)

also vanishes and the supersymmetry may be dynamically broken if $N > k$. It agrees with the discussion in [33] and the string theoretical explanation in [29, 30].

The $N$ ordered integers chosen from integers mod $k$ correspond to the number of rows of the Young diagram within $N \times (k - N)$ boxes by the identification

$$\tilde{n}_a = \tilde{\nu}_a - a + (k - N),$$

(3.58)

where $\tilde{\nu}_a$ is the number of boxes of $a$-th row of the Young diagram restricted within the $N \times (k - N)$ boxes. (See Figure 1) The supersymmetric index for $N = 2$ supersymmetric CS theory can be written as the partition function which is normalized by the ground state partition function $Z_0$

$$I_{N=2}(S^1 \times \Sigma) = \frac{Z_{\text{SYMCS}}(S^1 \times \Sigma)}{Z_0(S^1 \times \Sigma)} = \sum_{R'} (\text{dim}_q R') \chi(\Sigma),$$

(3.59)

where the sum is taken over the representation $R'$ associated with the Young diagram within $N \times (k - N)$ boxes.

In particular, for the $M = T^3$ case, namely $\chi(\Sigma) = 0$, the index becomes

$$I_{N=2}(T^3) = \sum_{R'} 1 = \frac{k!}{N!(k - N)!},$$

(3.60)

if $k \geq N$, since the number of the Young diagram within $N \times (k - N)$ boxes is given by the binomial coefficient $kC_N = \frac{k!}{N!(k - N)!}$ (the number of choices of $N$ integers within $k$). The index (3.60) completely coincides with the value obtained in [33, 30]. (Incidentally, for $N = 1$ $U(N)$ supersymmetric CS theory, the index is formally given by $k - 2 C_N$ due to the quantum level shift $k \to k + \frac{N}{2}$.) Thus we find that the choice of the Young
The difference of the partition function between various vacua is just a phase. So it is not suitable to call it the ground state since each vacuum is at zero energy and supersymmetric.

Figure 1: An example of the correspondence between $\vec{n}$ and the restricted Young diagram (partition) for $k = 10$ and $N = 4$. The right-down and right-up edge of the boxes correspond to the black and white circle, respectively. (a) The empty box is for $\vec{n} = (3, 2, 1, 0)$. (b) The partition $\vec{\nu} = (6, 3, 2)$ is for $\vec{n} = (9, 5, 3, 0)$. (c) The full box is for $\vec{n} = (9, 8, 7, 6)$. The total number of the partitions is $\binom{10}{4} = 210$, which is the supersymmetric index of the $U(4)_{10}$ CS theory.

diagram corresponds to the choice of the supersymmetric vacua, which can be expressed by the brane configuration in M-theory [30]. (See also Figure 2) In this sense, the usual expression of the CS partition function via surgery, where the partition function is normalized to be $Z(S^1 \times S^2) = 1$, relates to the proper vacuum which is called above the “ground state”.

The index (3.59) is obviously invariant under the exchange $N \leftrightarrow (k - N)$. This fact also reflects the level-rank duality (mirror symmetry) between the three-dimensional supersymmetric YMCS theories of $U(N)$ at level $k$ and $U(k - N)$ at level $-k$.

3.7 The general $p$

We now discuss the case of the general $p$ and $\mu = 1$, where $M$ forms uniformly “round” shape which includes the round $S^3$ for $p = 1$. We first decompose the integral region of

\footnote{The difference of the partition function between various vacua is just a phase. So it is not suitable to call it the ground state since each vacuum is at zero energy and supersymmetric.}
The supersymmetric YMCS theory can be realized by a configuration with NS5-D3-(k, 1)5 branes in Type IIB string theory. The brane configuration is lifted up to a M5-M2-M5 system in M-theory on torus. The positions of M2 branes, which are interpreted by the vev of the Wilson loop, are quantized along the fiber direction. We depict the brane configuration by a diagram (b), which corresponds to the restricted Young diagram in Figure 1.

Figure 2: The supersymmetric YMCS theory can be realized by a configuration with NS5-D3-(k, 1)5 branes in Type IIB string theory. The brane configuration is lifted up to a M5-M2-M5 system in M-theory on torus. The positions of M2 branes, which are interpreted by the vev of the Wilson loop, are quantized along the fiber direction. We depict the brane configuration by a diagram (b), which corresponds to the restricted Young diagram in Figure 1.

Then the partition function (3.43) becomes the integral over the compact regions of $\tilde{\phi}_a$ and the summation over $(\mathbb{Z}_p)^r$ and $\mathbb{Z}^r$

$$Z_{\text{SYMCS}} = \frac{1}{|W|} \sum_{\vec{n} \in (\mathbb{Z}_p)^r} \sum_{\vec{m} \in \mathbb{Z}^r} \int_0^{2\pi} d\tilde{\phi} \prod_{a=1}^{r} \prod_{\alpha > 0} \left( 2 \sin \frac{\alpha(\tilde{\phi})}{2} \right)^{\chi(\Sigma)}
\times e^{ik\sum_{a=1}^{r} \left[ \tilde{\phi}_a m_a + \frac{\alpha}{2} (\tilde{\phi}_a + 2\pi n_a)^2 \right]} \tag{3.62}$$
Noting that $e^{ikpn^a} = e^{ikpna}$ for the integer $k$, $p$ and $n_a$ and using again the Poisson resummation formula

\[
\frac{1}{(2\pi)^r} \sum_{\vec{n} \in \mathbb{Z}^r} \sum_{\vec{m} \in (\mathbb{Z}_p)^N} \prod_{a=1}^r e^{ik[p(n_a+\pi)+m_a]} \tilde{\phi}_a
\]

\[
= \begin{cases} 
\frac{1}{k^r} \sum_{\vec{n} \in \mathbb{Z}^r} \prod_{a=1}^r \delta \left( \tilde{\phi}_a - \frac{2\pi n_a}{k} \right) & \text{for even } kp \\
\frac{1}{(kp)^r} \sum_{\vec{n} \in (\mathbb{Z}+\frac{1}{2})^r} \prod_{a=1}^r \delta \left( \tilde{\phi}_a - \frac{2\pi n_a}{kp} \right) e^{i\varphi(n_a)} & \text{for odd } kp 
\end{cases}
\]

for even $kp$ and using the Poisson resummation formula

\[
\sum_{\vec{m} \in (\mathbb{Z}_p)^N} r \prod_{a=1}^r e^{i2\pi p n_a m_a} = \delta_{\vec{m},\vec{0}}.
\]

Inserting (3.63) into (3.62), we can integrate $\tilde{\phi}_a$ explicitly, then we get the partition function expressed as the $q$-deformed two-dimensional YM theory

\[
Z_{\text{SYMCS}}^{\text{even } kp} = \frac{C}{k^r|W|} \sum_{\vec{n} \in \mathbb{Z}^r} \prod_{a>0} [\alpha(n)]_q^{\chi(\Sigma)} q^{\frac{1}{2}p \sum_{a=1}^r n_a^2},
\]

if $kp$ is even, where $q = e^{\frac{2\pi i}{kp}}$. In particular, if we choose $G = U(N)$ and $M = S^3$, namely $p = 1$ and $\chi(\Sigma) = 2$, we obtain the partition function on $S^3$

\[
Z_{\text{SYMCS}}(S^3) = \frac{C}{k^N|W|} \sum_{\vec{n}} \prod_{1 \leq a < b \leq N} [n_a - n_b] q^{\frac{1}{2} \sum_{a=1}^N n_a^2},
\]

where the summations are taken over $(\mathbb{Z}_k)^N$ for even $k$ and $(\mathbb{Z}_k + \frac{1}{2})^N$ for odd $k$.

If $p > 1$ in general and $kp$ is odd, the expression of the partition function becomes more complicated due to the phase factors. A similar dependence on $k$ whether even or odd is reported in the exact evaluation of the localized integral [39].

### 3.8 The Wilson loop

As explained above, the supersymmetric Wilson loop operator is $Q$-closed but not $Q$-exact. So we can also evaluate the vev of the Wilson loops without violating the localization structure in the supersymmetric YMCS theory.

At the localization fixed point, the Wilson loop takes the value

\[
W(C)|_{\text{fixed points}} = Tr_R e^{i\phi} = \frac{\sum_{w \in W} (-1)^w e^{iw(\rho+\Lambda_R)\phi}}{\sum_{w \in W} (-1)^w e^{iw(\rho)\phi}} \equiv W_R(\phi),
\]

(3.66)
where \( w \) is the element of the Weyl group \( W \) and \( \Lambda_R \) is the highest weight (Young diagram) corresponding to the representation \( R \). Furthermore, as we have seen, using the Poisson resummation and integrating \( \phi \) explicitly in the \( p \to \infty \) limit, \( \phi \)'s are fixed at the discrete integer set \( \phi_a = \frac{2\pi n_a}{k} \). The vev of the Wilson loop can be evaluated by

\[
\langle W(C) \rangle = \frac{Z^{-1}_{\text{SYMCS}}}{k^r|W|} \sum_{\vec{n} \in \mathbb{Z}^r} \prod_{\alpha > 0} \left(2 \sin \frac{\pi}{k} \alpha(n)\right)^{\chi(S)} W_R \left(\frac{2\pi \vec{n}}{k}\right) e^{i \frac{2\pi}{k} \sum_{a=1}^{r} n_a^2}.
\]

(3.67)

If we restrict the sum at the ground state \( n_a = \rho_a \) only, then it recovers the (unknot) Wilson loop in the bosonic CS theory on \( S^3 \) obtained from the surgery

\[
\langle W(C) \rangle |_{\text{ground state}} = W_R \left(\frac{2\pi \vec{\rho}}{k}\right) = \prod_{\alpha > 0} \frac{\sin \frac{\pi}{k} \alpha(\Lambda_R + \rho)}{\sin \frac{\pi}{k} \alpha(\rho)} = \text{dim}_q R,
\]

(3.68)

with \( q = e^{\frac{2\pi i}{k}} \).

\section{Including Matters}

\subsection{Localization for chiral superfield}

So far, we have investigated the supersymmetric YMCS theory without matter multiplets. In this section, we would like to include the matters following the formulation of the equivariant cohomology introduced above.

First of all, we start with the \( \mathcal{N} = 2 \) supersymmetric transformations of the chiral superfield in three-dimensions as well as the vector (gauge) multiplet. The chiral superfield consists of the complex scalar \( X \), the chiral fermion \( \psi \) and the auxiliary complex scalar field \( F_c \). We do not consider the mass for the chiral superfield for a while. We will introduce the mass of the field later.

As well as the vector multiplet, we obtain the BRST transformations from the \( \mathcal{N} = 2 \) supersymmetric transformations for the chiral superfields (see Appendix B)

\[
Q X = \psi, \quad Q \psi = -i(D_{\kappa} X - i \sigma \cdot X), \\
Q Y_{\bar{z}} = -i(D_{\kappa} \chi_{\bar{z}} - i \sigma \cdot \chi_{\bar{z}}), \quad Q \chi_{\bar{z}} = Y_{\bar{z}}.
\]

(4.1)

Note that \( Y_{\bar{z}}, \chi_{\bar{z}} \) and their hermite conjugate coming from the anti-chiral superfield act as complex vector fields on \( \Sigma \). So introducing the (0,1)-form on \( \Sigma \) by \( Y_c \equiv Y_{\bar{z}} d\bar{z} \) for the
bosonic fields and $\chi_c \equiv \chi zd\bar{z}$, then the BRST transformations can be written by a simpler form

$$QX = \psi, \quad Q\psi = -i(\mathcal{L}_V X - \delta_\Phi X),$$

$$QY_c = -i(\mathcal{L}_V \chi_c - \delta_\Phi \chi_c), \quad Q\chi_c = Y_c,$$

(4.2)

where $\delta_\Phi X = i\Phi \cdot X$ is the gauge transformation with respect to the gauge parameter $\Phi$ and the coupling with the vector multiplets $\Phi \cdot X$ depends on the representation of the chiral superfield. Thus we have constructed the BRST symmetry, which satisfies obviously

$$Q^2 = -i(\mathcal{L}_V - \delta_\Phi).$$

(4.3)

Therefore we can argue the localization for the chiral superfields by using the equivariant cohomology of $Q$ in the same way as the vector multiplet. The $Q$-exact action, which is needed for the localization, is nothing but the matter part of the supersymmetric YM action. Introducing the vector notation of the matter fields $\vec{B}_m = (X,Y_c)$ for the bosons and $\vec{F}_m = (\psi,\chi_c)$ for the fermions, the action can be written by

$$S_{\text{matter}} = \frac{1}{2} Q \int_M \text{Tr} \left[ \vec{F}_m \wedge *Q\vec{F}_m - 2i\chi_c \wedge *\mu_c - 2i\chi_c^\dagger \wedge *\mu_c \right],$$

(4.4)

where $\mu_c \equiv \pi^* d_A X + i \frac{\partial W(X)}{\partial X} \kappa$ is the moment map which gives the F-term constraint with the superpotential $W(X)$. The bosonic part of $S_{\text{matter}}$ becomes quadratic and positive definite in $Q\vec{F}_m$ and $\mu_c$

$$S_{\text{matter}}|_{\text{boson}} = \frac{1}{2} \int_M \text{Tr} \left[ Q\vec{F}_m \wedge *Q\vec{F}_m + 2\mu_c \wedge *\mu_c \right],$$

(4.5)

after integrating out the auxiliary field $Y_c$. So we can conclude that the path integral for the matter fields is localized at the BRST fixed point $Q\vec{F}_m = 0$ and $\mu_c = 0$ by using the coupling independence of the $Q$-exact action. Note that the F-term constraint $\mu_c = 0$ is strict on the localization while the D-term constraint admits the higher critical points $\mu_r \neq 0$, since the F-term constraint does not relate to the complexification of $\Phi$. So we always have to take into account the F-term constraints when we are considering the localization fixed points.

The contribution from the chiral matter fields to the 1-loop determinants can be
derived in the similar way as the vector multiplet case. It is exactly given by

\[ e^{-S_{\text{matter}}} = \sqrt{\frac{\det(\delta(QB_m)\delta(Q\bar{F}_m))}{\det(\delta(QF_m)\delta(Q\bar{F}_m))}} \]

\[ = \frac{\det_X(-iL_V - \rho(\phi))}{\det_X(-iL_V - \rho(\phi))} \delta(Q\bar{F}_m)\delta(\bar{F}_m), \quad (4.6) \]

where \( \rho(\phi) \) is the weights of the representation \( R \) of \( X \), that is, \( \rho(\phi) = \alpha(\phi) \) in the adjoint representation and \( \rho(\phi) = \phi_a \) in the fundamental representation, for example. We here note that the fields in the chiral superfields are complex valued and the determinant admits some phases because of the absence of the absolute value.

Now let us introduce the mass for the matter fields. There are two possibilities to give the mass to the chiral superfields:

One comes from the F-term. The quadratic term in the superpotential induces the explicit mass term for \( X \). As we mentioned above, the F-term constraint is important to solve the fixed point equation. The fixed point equation sometimes removes the zero modes of the matter fields at the low energy. We give an example of this case in the next subsection.

The other is introduced as the eigenvalue of the Lie derivative \( L_V \). In fact, if we assume that the matter fields has a twisted boundary condition

\[ \Psi(z, \bar{z}, \theta + 2\pi \ell) = \Psi(z, \bar{z}, \theta)e^{2\pi im}, \quad (4.7) \]

along the fiber direction, the boundary condition induces the mass for \( X \) by the so-called Scherk-Schwarz mechanism [40]. This also can be understood as the mass term induced by the \( \Omega \)-background [6] from the point of view of two-dimensional theory on \( \Sigma \). In this sense, the eigenvalues of \( L_V \) for the matter fields are modified to \( i \left( -\frac{n}{\ell} + \frac{2m}{\ell} \right) \) for \( n \in \mathbb{Z} \). Here \( m \) is the mass of the matter fields measured in the unit of the Kaluza-Klein mass scale of the \( S^1 \) fiber.

In conformal field theory on \( M \), the mass is determined by the dimension of fields. If we assign the dimension \( \Delta \) to the lowest component \( X \), then \( \psi, \chi_c \) and \( Y_c \) also have the same dimension \( \Delta \), because of the twisting of our formulation. (See Appendix B.) In the canonical assignments, we should set \( \Delta = 1/2 \). We must impose the boundary conditions

33
of these fields to get the correct mass with the dimensions. It is interesting that all fields in the matter multiplet have the fermionic twisted boundary condition along the $S^1$ fiber

$$\Psi(z, \bar{z}, \theta + 2\pi \ell) = -\Psi(z, \bar{z}, \theta),$$  \hfill (4.8)

for the conformal matter with the canonical dimension $\Delta = 1/2$ on $M$.

Once the superpotential vanishes and the eigenvalues of $L_V$ are given by the conformal dimension, we can evaluate the 1-loop determinant (4.6) explicitly. If we expand the fields by the eigenmodes of $L_V$

$$X(z, \bar{z}, \theta) = \sum_{n \in \mathbb{Z}} X_n(z, \bar{z}) e^{-i(n-\Delta)\theta/\ell}, \quad \chi_{c,n}(z, \bar{z}) = \sum_{n \in \mathbb{Z}} \chi_{c,n}(z, \bar{z}) e^{-i(n-\Delta)\theta/\ell}.$$  \hfill (4.9)

Noting that $X_n$ and $\chi_{c,n}$ have the same eigenvalue and the 0-form and 1-form sections of the line bundles $\mathcal{O}(-pn + |p\Delta|)$ over $\Sigma$, respectively, where $|x| \equiv \max\{n \in \mathbb{Z} | n \leq x\}$ is the floor function, the difference of the number of these modes on $\Sigma$ between $X_n$ and $\chi_{c,n}$ can be obtained from the Hirzebruch-Riemann-Roch theorem

$$\dim \Omega^0(\Sigma, \mathcal{O}(-pn + |p\Delta|) \otimes V_\rho) - \dim \Omega^1(\Sigma, \mathcal{O}(-pn + |p\Delta|) \otimes V_\rho) = \frac{1}{2} \chi(\Sigma) - pn + |p\Delta| + \rho(m),$$  \hfill (4.10)

where $\rho(m)$ is the contribution from the first Chern class of the $U(1)$ gauge fields in the matter representation $R$, as well as the vector multiplet. Since there are infinitely many pairs of $X_n$ and $\chi_{c,n}$ as the fields on $\Sigma$, the contribution from the matter to the 1-loop determinant is given by

$$\prod_{n \in \mathbb{Z}} \frac{\det_{\chi_{c,n}}(-iL_V - \rho(\phi))}{\det_{X_n}(-iL_V - \rho(\phi))} = \prod_{\rho \in R} \prod_{n \in \mathbb{Z}} \left( -\frac{n - \Delta}{\ell} - \rho(\phi) \right)^{-\frac{1}{2} \chi(\Sigma) + pn - |p\Delta| - \rho(m)},$$  \hfill (4.11)

In particular, if we consider the case of $M = S^3$ ($\chi(\Sigma) = 2$ and $p = 1$) and assume $\Delta < 1$, then the determinant becomes

$$\prod_{\rho \in R} \prod_{n \in \mathbb{Z}} \left( -\frac{n - \Delta}{\ell} - \rho(\phi) \right)^{-n-1} = \prod_{\rho \in R} \prod_{n=1}^{\infty} \left( -\frac{n + 1 - \Delta + \ell \rho(\phi)}{n - 1 + \Delta - \ell \rho(\phi)} \right)^{n},$$  \hfill (4.12)

which agrees with the results in [8, 10, 11] up to a phase factor.
The determinant (4.11) contains the phase in general, but we are interested in the matters only in the self-conjugate representation in the present paper. So we now concentrate on the absolute value of the determinant, which becomes

\[
\prod_{\rho \in \mathbb{R}} \prod_{n \in \mathbb{Z}} \left| \frac{n - \frac{1}{2}}{\ell} + \rho(\phi) \right|^{-\frac{1}{2} \chi(\Sigma) + pn - \lfloor p/2 \rfloor - \rho(m)} = \prod_{\rho \in \mathbb{R}} \prod_{n=1}^{\infty} \left| \frac{(n - \frac{1}{2})^2}{\ell^2} - \rho(\phi)^2 \right|^{-\frac{1}{2} \chi(\Sigma) - \lfloor p/2 \rfloor - \rho(m)} \\
\times \prod_{\rho \in \mathbb{R}} \left| n - \frac{1}{2} + \ell \rho(\phi) \right|^{pn} \\
\times \prod_{n=1}^{\infty} \left| \frac{n - \frac{1}{2} + \ell \rho(\phi)}{n + \frac{1}{2} - \ell \rho(\phi)} \right|^{pn},
\]

(4.13)

when the matter multiplet has the canonical dimension \(\Delta = 1/2\), where we have used the infinite product expression of the cosine function and the zeta function regularizations. If the matter field is in the adjoint or self-conjugate (hypermultiplet) representation, the dependence of the phase and \(\rho(m)\) disappears and the determinant simplifies to

\[
\ell^{-\chi(\Sigma) \dim G} \prod_{\alpha > 0} (2 \cos \pi \ell \phi(\alpha))^{-\chi(\Sigma) + \varepsilon(p)},
\]

(4.14)

for the adjoint representation and

\[
\ell^{-\chi(\Sigma)r} \prod_{\alpha = 1}^{r} (2 \cos \pi \ell \phi_{\alpha})^{-\chi(\Sigma) + \varepsilon(p)},
\]

(4.15)

for the self-conjugate fundamental representation \(\Box \oplus \Box\), where \(\varepsilon(p) \equiv p - 2 \lfloor p/2 \rfloor = 0\) or 1 such that \(p = \varepsilon(p) \mod 2\). The appearance of the cosine function \(\cos x \sim 1 + e^{ix}\) might be related to the fermionic nature (4.8) of the matter fields with the canonical dimension. These formulae agree with the results in [8] for \(M = S^3\).

4.2 \(\mathcal{N} = 3\) YMCS theory

We here comment on the case that the \(\mathcal{N} = 2\) supersymmetric YMCS theory with a single massive chiral superfield in the adjoint representation, whose mass is given by the superpotential. The on-shell fields in the vector multiplet of the YMCS theory have the
topologically induced mass of \( k g^2 / 4 \pi \), where \( g \) is the gauge coupling constant. If we tune the mass of the adjoint chiral superfield to \( k g^2 / 4 \pi \) which is the same mass as the vector multiplet, the \( \mathcal{N} = 2 \) supersymmetry enhances to \( \mathcal{N} = 3 \) since \( SO(3) \) R-symmetry now acts on the triplet of the adjoint scalars in the \( \mathcal{N} = 2 \) vector multiplet and chiral superfield. This bare complex mass is given by the superpotential \( W = \frac{k}{8\pi} \text{Tr} X^2 \). The brane realization of this system is discussed in [27].

However this is essentially in the UV picture. In the IR limit, all massive fields compared with the mass scale \( k g^2 / 4 \pi \) in the supersymmetric YMCS theory are integrated out and flows to the \( \mathcal{N} = 3 \) supersymmetric CS theory with the conformal symmetry. At the conformal fixed points, the adjoint matter \( X \) decouples and the residual matter contents reduce to the \( \mathcal{N} = 2 \) vector multiplet only. In the localization language, this is the consequence of the fixed point equation \( X = 0 \) from the F-term constraint \( \mu_c = 0 \).

Thus, in the low energy limit, we obtain the partition function of the \( \mathcal{N} = 3 \) supersymmetric YMCS theory which is the same as the \( \mathcal{N} = 2 \) one. Then, of course, the supersymmetric index of this system on \( T^3 (\chi(\Sigma) = 0) \) is the same as the index for \( \mathcal{N} = 2 \) theory

\[
\mathcal{I}_{\mathcal{N}=3}(T^3) = \frac{k!}{N!(k-N)!}.
\]

This agrees with the observation in [30].

4.3 ABJM theory

We now apply the localization procedure to the ABJM theory [25] or its generalization [26].

The theory has the product of the gauge groups \( U(N + l) \times U(N) \) and there are the CS couplings with the opposite level \( k \) and \(-k\). We denote this by the symbol \( G = U(N + l)_k \times U(N)_{-k} \) and assume \( l \geq 0 \) in the following. The ABJM theory is the case of \( l = 0 \) and we call the ABJ theory for the general \( l \). In the UV picture, the YMCS theory contains a set of the vector multiplets \( (A, \sigma, Y_r; \lambda, \eta, \chi_r) \) and \( (\tilde{A}, \tilde{\sigma}, \tilde{Y}_r; \tilde{\lambda}, \tilde{\eta}, \tilde{\chi}_r) \), the chiral superfield in the adjoint representation \( (X, Y_c; \psi, \chi_c) \) and \( (\tilde{X}, \tilde{Y}_c; \tilde{\psi}, \tilde{\chi}_c) \), four chiral superfields \( (Z_i, Y_c Z_i; \psi Z_i, \chi_c Z_i) \) in the bifundamental and and \( (\tilde{Z}_i, Y_c \tilde{Z}_i; \tilde{\psi} \tilde{Z}_i, \tilde{\chi}_c \tilde{Z}_i) \) in
the anti-bifundamental representation for $i = 1, 2$.

The BRST transformations are

\[
Q A = \lambda, \quad Q \lambda = -i(\mathcal{L}_V A - d_A \Phi),
\]
\[
Q \bar{A} = \bar{\lambda}, \quad Q \bar{\lambda} = -i(\mathcal{L}_V \bar{A} - d_{\bar{A}} \bar{\Phi}),
\]
\[
Q \Phi = 0, \quad Q \Phi = 0,
\]
\[
Q \bar{\Phi} = 2\eta, \quad Q \bar{\eta} = -i(\mathcal{L}_V \bar{\Phi} - i[\bar{\Phi}, \bar{\Phi}]),
\]
\[
Q \bar{\Phi} = 2\bar{\eta}, \quad Q \bar{\eta} = -i(\mathcal{L}_V \bar{\Phi} - i[\bar{\Phi}, \bar{\Phi}]),
\]
\[
Q Y_r = -i(\mathcal{L}_V \chi_r - i[\Phi, \chi_r]), \quad Q \chi_r = Y_r,
\]
\[
Q \bar{Y}_r = -i(\mathcal{L}_V \bar{\chi}_r - i[\bar{\Phi}, \bar{\chi}_r]), \quad Q \bar{\chi}_r = \bar{Y}_r,
\]

for the vector multiplets, where $\Phi = \nu_V A + i\sigma$ and $\bar{\Phi} = \nu_V \bar{A} + i\bar{\sigma}$,

\[
Q X = \psi, \quad Q \psi = -i(\mathcal{L}_V X - i[\Phi, X]),
\]
\[
Q \bar{X} = \bar{\psi}, \quad Q \bar{\psi} = -i(\mathcal{L}_V \bar{X} - i[\bar{\Phi}, \bar{X}]),
\]
\[
Q Y_c = -i(\mathcal{L}_V \chi_c - i[\Phi, \chi_c]), \quad Q \chi_c = Y_c,
\]
\[
Q \bar{Y}_c = -i(\mathcal{L}_V \bar{\chi}_c - i[\bar{\Phi}, \bar{\chi}_c]), \quad Q \bar{\chi}_c = \bar{Y}_c,
\]

for the chiral superfields in the adjoint representation, and

\[
Q Z_i = \psi^Z_i, \quad Q \psi^Z_i = -i(\mathcal{L}_V Z_i - i[\Phi Z_i - Z_i \bar{\Phi}]),
\]
\[
Q \bar{Z}_i = \bar{\psi}^Z_i, \quad Q \bar{\psi}^Z_i = -i(\mathcal{L}_V \bar{Z}_i - i[\bar{\Phi} \bar{Z}_i - \bar{Z}_i \Phi]),
\]
\[
Q Y_c^Z_i = -i(\mathcal{L}_V \chi_c^Z_i - i(\Phi \chi_c^Z_i - \chi_c^Z_i \bar{\Phi})), \quad Q \chi_c^Z_i = Y_c^Z_i,
\]
\[
Q \bar{Y}_c^Z_i = -i(\mathcal{L}_V \bar{\chi}_c^Z_i - i(\bar{\Phi} \bar{\chi}_c^Z_i - \bar{\chi}_c^Z_i \Phi)), \quad Q \bar{\chi}_c^Z_i = \bar{Y}_c^Z_i,
\]

for the bifundamental and anti-bifundamental matters. The moment maps (D-term and F-term constraints) corresponding to the auxiliary fields are given by

\[
\mu_r = \frac{\kappa A \Phi_\Sigma}{\kappa A d_\Sigma} + [X, X^\dagger] + \sum_{i=1,2}(|Z_i|^2 - |\bar{Z}_i|^2),
\]
\[
\bar{\mu}_r = \frac{\kappa A \bar{\Phi}_\Sigma}{\kappa A d_{\bar{\Sigma}}} + [\bar{X}, \bar{X}^\dagger] - \sum_{i=1,2}(|Z_i|^2 - |\bar{Z}_i|^2),
\]
\[
\mu_c = \pi^* d_{\Sigma} X - i[A, X] + i\kappa \frac{\partial W}{\partial X},
\]
\[
\bar{\mu}_c = \pi^* d_{\bar{\Sigma}} \bar{X} - i[A, \bar{X}] + i\kappa \frac{\partial W}{\partial \bar{X}},
\]
\[
\mu_{c}^Z_i = \pi^* d_{\Sigma} Z_i - iA Z_i + iZ_i A + i\kappa \frac{\partial W}{\partial Z_i},
\]
\[
\mu_{\bar{c}}^Z_i = \pi^* d_{\bar{\Sigma}} \bar{Z}_i - i\bar{A} \bar{Z}_i + i\bar{Z}_i \bar{A} + i\kappa \frac{\partial W}{\partial \bar{Z}_i},
\]

where

\[
W = \text{Tr} \left[ \frac{k}{8\pi} X^2 - \frac{k}{8\pi} \bar{X}^2 + \sum_{i=1,2} (Z_i X \bar{Z}_i + \bar{Z}_i X \bar{Z}_i) \right],
\]
is the superpotential of the UV lagrangian for the $N = 3$ supersymmetric YMCS theory with the ABJM (ABJ) matter contents.

We can construct a $Q$-exact YM action from the above BRST transformations and the moment maps as well as we have discussed so far. And also, 1-loop determinants are obtained from the field derivatives of the BRST transformations. However all fields do not contribute to the determinants because the massive fields are integrated out and disappear in the low energy limit.

The adjoint scalars $X$ and $\tilde{X}$ are massive by the superpotential, so we can integrate out these fields. The superpotential reduces to

$$W = \frac{4\pi}{k} \text{Tr} \left[ Z_1 \tilde{Z}_1 Z_2 \tilde{Z}_2 - Z_1 \tilde{Z}_2 Z_2 \tilde{Z}_1 \right],$$

(4.22)

which leads to the enhancement of the supersymmetry at the conformal point. In this low energy limit, the adjoint scalars $X$ and $\tilde{X}$ disappears. The partition function is obtained from the 1-loop determinants of the vector multiplets and the (anti-)bifundamental matters. The result is

$$Z_{\text{ABJ}}^{U(N+1)\times U(N)_k} = \frac{1}{(N+l)!N!} \sum_{\vec{m},\vec{\tilde{m}}} \frac{\prod_{a<b} 2 \sin \frac{\phi_a - \phi_b}{2} \prod_{c<d} 2 \sin \frac{\tilde{\phi}_c - \tilde{\phi}_d}{2}}{\prod_{a,c} 2 \cos \frac{\phi_a - \tilde{\phi}_c}{2}} 2^{(\chi(\Sigma) - \varepsilon(p))} \chi(\Sigma),$$

(4.23)

where we have used the fact that the bifundamental matters, which are in the self-conjugate representation, have the canonical dimension $\Delta = 1/2$. We ignore the overall scale factor in the following. The partition function (4.23) agrees with the result for $S^3$ [8, 11], which is the case of $p = \mu = 1$ and $\chi(\Sigma) = 2$ of ours.

Let us first consider the supersymmetric index for this system. Setting $p = 0$ and using the Poisson resummation formula, the partition function on $M = S^1 \times \Sigma$ becomes

$$Z_{\text{ABJ}}^{U(N+1)\times U(N)_k}(S^1 \times \Sigma) = \frac{1}{(N+l)!N!} \sum_{\vec{n},\vec{\tilde{n}}} \left( \prod_{a<b} 2 \sin \frac{\pi}{k} (n_a - n_b) \prod_{c<d} 2 \sin \frac{\pi}{k} (\tilde{n}_c - \tilde{n}_d) \right) \chi(\Sigma),$$

(4.24)
where \( \vec{n} \in (\mathbb{Z}_k)^{N+l} \) and \( \vec{n}^\prime \in (\mathbb{Z}_k)^N \). This partition function includes various phases (vacuum configurations), but we can easily classify them graphically by using the brane configuration (the M2-M5 system on M-theory torus), see Figure 3. If some \( n_a \) and \( \tilde{n}_b \) coincide with each other, these M2 branes are decoupled from the bound state with the M5-brane, since the connected fractional M2’s are promoted a single M2. The maximal number of the connected fractional M2 is \( N \) for the ABJ theory. In this maximal phase, the partition function (4.24) is factorized into

\[
Z^{U(N+l)k \times U(N)_{-k}}_{\text{ABJ}}(S^1 \times \Sigma) = Z^{U(l)k}_{N=2}(S^1 \times \Sigma) \times Z^{U(N)k \times U(N)_{-k}}_{\text{ABJM}}(S^1 \times \Sigma),
\]  

(4.25)

where \( Z^{U(l)k}_{N=2} \) is the same partition function as the pure \( \mathcal{N} = 2 \) (or equivalently \( \mathcal{N} = 3 \)) theory with the gauge group \( G = U(l)k \) on \( S^1 \times \Sigma \) and

\[
Z^{U(N)k \times U(N)_{-k}}_{\text{ABJM}}(S^1 \times \Sigma) = \frac{1}{N!} \sum_{\vec{n} \in (\mathbb{Z}_k)^N} \prod_{1 \leq a < b \leq N} \left( \frac{\tan \frac{\pi}{k}(n_a - n_b)}{2^{2N} \cos \frac{\pi}{k}(n_a - n_b)} \right)^{2\chi(\Sigma)},
\]  

(4.26)

since \( n_a = \tilde{n}c \) for the connected fractional M2. This factorization also can be understood from the brane configuration in Figure 3.

If we now consider the case of \( \chi(\Sigma) = 0 \), namely \( M = T^3 \), we get the supersymmetric index as the number of terms (configurations) in the partition function (4.25). Then we find

\[
I^{U(N+l)k \times U(N)_{-k}}_{\text{ABJ}} = I^{U(l)k}_{N=2} \times I^{U(N)k \times U(N)_{-k}}_{\text{ABJM}},
\]  

(4.27)

where

\[
I^{U(l)k}_{N=2} = kC_l = \frac{k!}{l!(k-l)!},
\]  

(4.28)

\[
I^{U(N)k \times U(N)_{-k}}_{\text{ABJM}} = kC_N = \frac{k!}{N!(k-N)!}.
\]  

(4.29)

This index is also obvious from the brane configuration. Using the mirror symmetry between \( U(l)k \) and \( U(k-l)_{-k} \) theories, which means \( I^{U(l)k}_{N=2} = I^{U(k-l)_{-k}}_{N=2} \), we can immediately see the equivalence of the supersymmetric index

\[
I^{U(N+l)k \times U(N)_{-k}}_{\text{ABJ}} = I^{U(N)k \times U(N+k-l)_{-k}}_{\text{ABJ}},
\]  

(4.30)

This is a proof of the equivalence suggested in [26] at the supersymmetric index level.
which contains the fractional M2 branes in general. The coincide integers $n_a = \tilde{n}_b$ stands
for the connected fractional M2’s, which can decouple from the CS coupling (remove from the tip of $\mathbb{C}^4/\mathbb{Z}_k$) since the corresponding quadratic term from the CS coupling vanishes. In particular, if all of the fractional M2 branes connect with each other, that is $\tilde{n}_a = n_a$ with a fixed order, then we obtain the partition function for the non-fractional $N$ M2 branes

$$Z_{NM2}^{M2}(M) = \frac{1}{2^{2N(\chi(\Sigma)-\varepsilon(p))}N!} \sum_{\tilde{n} \in (\mathbb{Z}_k)^N} \prod_{a<b} \frac{(2 \sin \frac{\pi}{k} (n_a - n_b))^{2\chi(\Sigma)}}{(2 \cos \frac{\pi}{k} (n_a - n_b))^{4(\chi(\Sigma)-\varepsilon(p))}}. \quad (4.32)$$

It is interesting to discuss the large $N$ behavior of the above partition function written in terms of the discrete sum, but we leave it for future work.

### 5 Conclusion and Discussion

In this paper, we have investigated the supersymmetric YMCS theory on the Seifert manifold. The partition function and the Wilson loops of YMCS theory and CS theory at low energy can be evaluated exactly by using the localization theorem. We found that the partition function reduces to the finite dimensional integral over the eigenvalues of the adjoint scalar field and the summation over the classical flux configurations. In the particular cases, the finite dimensional integral further reduces to the summation over the discrete integer set owing to the Poisson resummation formula.

Källén’s cohomological field theory approach makes clear the relation to the equivariant cohomology in the localization. We understand deeper the meanings of the fixed points and constraints and how to work the localization in the supersymmetric YMCS theory. The united cohomological approach is easily formulated on the various topologically distinguished three-dimensional manifolds possessing the $U(1)$ isometry.

We also derived the supersymmetric indexes of the YMCS theory, which completely coincide with the expected counting of the brane configurations. This derivation of the index can be extended to more various CS theories with matters [41] and we can discuss the dynamical supersymmetry breaking for these theories. It is also interesting to extend these counting to the generalized index like the superconformal index. We may find the relationships and dualities between the indexes and partition functions in various
dimensions \cite{42,43,44,45,46,47,48,49} through the localization of the CS theories on the Seifert manifolds.

We did not specially discuss in the present paper the asymptotic behavior of the partition function in the large $N$ limit although it is important to know the M-theoretical nature of the supersymmetric YMCS theory. We may discuss the large $N$ limit by using the saddle point approximation of the matrix model as well as discussed in \cite{50,11,51}. On the other hand, we find the representation of the partition function as the summation over the non-colliding discrete integer set. This fact strongly suggests there exist a suitable form for the large $N$ expansion at the strong coupling and a free fermion description of the partition function \cite{52}. We expect that these understandings of the relationships may lead to the remarkable Airy function interpretation of the partition function \cite{53}. The large $N$ limit brings us about the relation to the large $N$ reduced matrix models as discussed in \cite{54,55,56,57}. The reduced matrix model deconstructs the planar limit of the continuous field theory or M-theory in the large $N$ limit. This might be a good test for the non-perturbative definition of string theory or M-theory.

The cohomological localization can be extended to five-dimensional contact manifold \cite{58}. We can also discuss the localization of the CS and YM theories on the topologically distinguished five-dimensional manifolds with the $U(1)$ isometry, including the case of $S^5$ \cite{59}. However, in contrast with the three-dimensional case, the (physical) supersymmetric gauge theory and topological twisting theory differ with each other in general on the higher dimensional manifolds, since the topological twist changes the spin, as a consequence, the number of the zero modes from the original theory. So we need more careful analysis for the higher dimensions, but the cohomological localization may be still useful for some special cases like the circle bundle over the (hyper-)Kähler manifolds like K3 surface. It is interesting to relate the partition functions and indexes of these higher dimensional theories with the instanton (BPS soliton) counting or the invariants of the lower dimensional theories.

KO would like to thank the participants in the Summer Institute 2011 in Fuji-Yoshida and workshops of the JSPS/RFBR collaboration (“synthesis of integrabilities arising from gauge-string duality”) for lucid lectures and useful discussions.

A  Topological Twist for Vector Multiplet

In this appendix we perform the topological twist of the vector multiplet following [15]. The $\mathcal{N} = 2$ supersymmetric transformations for the vector multiplet on $M$ are

$$
\begin{align*}
\delta A_\mu &= -\frac{i}{2}(\epsilon \gamma_\mu \lambda - \tilde{\lambda} \gamma_\mu \epsilon), \\
\delta \sigma &= \frac{i}{2}(\epsilon \lambda - \tilde{\lambda} \epsilon), \\
\delta \lambda &= -\frac{i}{2} \gamma^{\mu\nu} \epsilon F_{\mu\nu} + D\epsilon - i \gamma_\mu \epsilon D_\mu \sigma + \frac{1}{\ell} \epsilon \sigma, \\
\delta \tilde{\lambda} &= \frac{i}{2} \gamma^{\mu\nu} \tilde{\epsilon} F_{\mu\nu} + D\tilde{\epsilon} - i \gamma_\mu \tilde{\epsilon} D_\mu \sigma + \frac{1}{\ell} \tilde{\epsilon} \sigma, \\
\delta D &= -\frac{i}{2} \epsilon \gamma_\mu D_\mu \lambda - \frac{i}{2} D_\mu \lambda \gamma_\mu \epsilon + \frac{i}{2} \epsilon [\lambda + \tilde{\lambda} \epsilon, \sigma] + \frac{1}{\ell^2} (-\epsilon \lambda + \tilde{\lambda} \epsilon).
\end{align*}
$$

We obey the convection used in [10] except for the Grassmann nature of $\epsilon$, $\tilde{\epsilon}$ and $\delta$. We take $\epsilon$ and $\tilde{\epsilon}$ to be the Grassmann even and $\delta$ to be the Grassmann odd.

We define the one-form valued twisted fermions $\lambda_\mu$ and $\tilde{\lambda}_\mu$ by

$$
\lambda = \gamma_\mu \epsilon \lambda_\mu, \quad \tilde{\lambda} = \tilde{\epsilon} \gamma_\mu \tilde{\lambda}_\mu. \tag{A.2}
$$

We use gamma matrix identities

$$
\begin{align*}
\gamma_\mu \gamma_\nu &= g_{\mu\nu} + i \epsilon_{\mu\nu\rho} \gamma^\rho, \\
\gamma_\mu \gamma_\nu - \gamma_\nu \gamma_\mu &= -2 g_{\mu\rho} \gamma_\rho + 2 g_{\mu\nu} \gamma_\nu, \\
\{\gamma_\mu, \gamma_\nu\} &= 2 g_{\mu\nu}. 
\end{align*}
$$

and substitute (A.2) into (A.1), the supersymmetric transformations for the vector mul-
along the fiber direction. If we take constant spinor $\bar{\epsilon}\epsilon$ supersymmetric transformation explicitly in each component as

$$A$$

$\lambda\bar{\lambda}$ becomes vector becomes

$$\delta A_\mu = -\frac{i}{2}(\bar{\epsilon}\gamma_\mu\lambda - \bar{\lambda}\gamma_\mu\epsilon) = -\frac{i}{2}\left(\lambda_\mu - \bar{\lambda}_\mu + i\epsilon_{\mu\nu}\bar{\epsilon}\gamma^\nu(\lambda^\nu + \bar{\lambda}^\nu)\right),
$$

$$\delta \sigma = \frac{1}{2}(\bar{\epsilon}\lambda - \bar{\lambda}\epsilon) = \frac{1}{2}\bar{\epsilon}\gamma^\mu\epsilon(\lambda_\mu - \bar{\lambda}_\mu),
$$

$$\delta(\bar{\epsilon}\lambda - \bar{\lambda}\epsilon) = -i2\bar{\epsilon}\gamma^\mu\epsilon D_\mu \sigma,
$$

$$\delta(\bar{\epsilon}\lambda + \bar{\lambda}\epsilon) = -\bar{\epsilon}\gamma^{\mu\nu}\epsilon F_{\mu\nu} + 2D + \frac{2}{\bar{\epsilon}}\sigma,
$$

$$\delta D = -\frac{i}{2}D_\mu(\bar{\epsilon}\gamma^\mu\lambda + \bar{\lambda}\gamma^\mu\epsilon) + \frac{i}{2}[\bar{\epsilon}\lambda + \bar{\lambda}\epsilon, \sigma] + \frac{1}{2\bar{\epsilon}}(-\bar{\epsilon}\lambda + \bar{\lambda}\epsilon).
$$

Here we also used the normalization condition $\bar{\epsilon}\epsilon = 1$. $V^\mu = \bar{\epsilon}\gamma^\mu\epsilon$ defines a Killing vector along the fiber direction. If we take constant spinor $\epsilon = (i, 0)^t$ and $\bar{\epsilon} = (0, i)^t$, the Killing vector becomes

$$\bar{\epsilon}\gamma^\alpha\epsilon = \delta^\alpha_3
$$

This allow us to take $A_\kappa$, $\lambda_\kappa$ and $\bar{\lambda}_\kappa$ to be $A_3$ and $\lambda_3$ and $\bar{\lambda}_3$. We now write down the supersymmetric transformation explicitly in each component as

$$\delta(A_1 + iA_2) = -i(\lambda_1 + i\lambda_2),$$

$$\delta(A_1 - iA_2) = i(\bar{\lambda}_1 - i\bar{\lambda}_2),$$

$$\delta A_\kappa = -\frac{i}{2}(\lambda_\kappa - \bar{\lambda}_\kappa),$$

$$\delta \sigma = \frac{1}{2}(\lambda_\kappa - \bar{\lambda}_\kappa),$$

$$\delta(\lambda_\kappa - \bar{\lambda}_\kappa) = -i2D_\kappa \sigma,$$

$$\delta(\lambda_\kappa + \bar{\lambda}_\kappa) = -\epsilon_{\mu\nu\kappa}F^{\mu\nu} + 2D + \frac{2}{\bar{\epsilon}}\sigma,
$$

$$\delta(\lambda_1 + i\lambda_2) = -2(F_{1\kappa} + iF_{2\kappa}) - 2iD_\kappa \sigma,$$

$$\delta(\bar{\lambda}_1 - i\bar{\lambda}_2) = -2(F_{1\kappa} - iF_{2\kappa}) - 2iD_\kappa \sigma,$$

$$\delta D = -\frac{i}{2}D_\kappa(\lambda_\kappa + \bar{\lambda}_\kappa) - \frac{i}{2}\left\{(D^1 - iD^2)(\lambda_1 + i\lambda_2) + (D^1 + iD^2)(\bar{\lambda}_1 - i\bar{\lambda}_2)\right\}
$$

$$+ \frac{i}{2}[\lambda_\kappa + \bar{\lambda}_\kappa, \sigma] - \frac{1}{2\bar{\epsilon}}(\lambda_\kappa - \bar{\lambda}_\kappa).
$$

We now introduce new fields $\lambda_z$, $\lambda_{\bar{z}}$, $\eta$, $\chi_r$ and $Y_r$ by

$$\lambda_z = -\frac{i}{2}(\lambda_1 + i\lambda_2)
$$

$$\lambda_{\bar{z}} = \frac{i}{2}(\bar{\lambda}_1 - i\bar{\lambda}_2)
$$

$$\eta = -\frac{i}{2}(\lambda_\kappa - \bar{\lambda}_\kappa)
$$

$$\chi_r = \frac{1}{2}(\lambda_\kappa + \bar{\lambda}_\kappa)
$$

$$Y_r = -i\epsilon_{\mu\nu\kappa}F^{\mu\nu}_\kappa + D + \frac{1}{\bar{\epsilon}}\sigma
$$

44
Rewriting (A.6) by these fields, we finally obtain the desired scalar BRST transformations (2.16):

\[
\begin{align*}
QA_z &= \lambda_z, \\
QA_{\bar{z}} &= \lambda_{\bar{z}}, \\
QA_{\kappa} &= \eta, \\
Q\sigma &= \iota \eta, \\
QY_r &= -i D_\kappa \chi_r + i [\chi_r, \sigma], \\
Q\chi_r &= Y_r,
\end{align*}
\]

(A.8)

where we have defined the BRST charge \(Q\) from the supercharge \(\delta\). They are also written in terms of the equivalent form notation:

\[
\begin{align*}
QA &= \lambda, \\
Q\lambda &= -i (-i d_A \sigma + \iota_V F), \\
Q\sigma &= \iota_V \lambda, \\
QY_r &= -i (\iota_V d_A X + [\sigma, \chi]), \\
Q\chi_r &= Y_r.
\end{align*}
\]

(A.9)

B  Topological Twist for Chiral Multiplet

Let us next consider topological twist of matter fields. The supersymmetric transformations for chiral multiplet on \(M\) are

\[
\begin{align*}
\delta X &= \bar{\epsilon} \psi', \\
\delta \psi' &= -i \gamma^\mu \epsilon D_\mu X - i \epsilon \sigma X + \frac{A}{t} \epsilon X + \bar{\epsilon} F_c, \\
\delta F_c &= -\epsilon (i \gamma^\mu \epsilon D_\mu \psi' - i \sigma \psi' - i \lambda X) - \frac{1}{2t} (2\Delta - 1) \epsilon \psi'.
\end{align*}
\]

(B.1)

We define the topologically twisted one-form fermion \(\psi_\mu\) similar manner as vector multiplet by

\[
\psi' \equiv \gamma^\mu \epsilon \psi_\mu.
\]

(B.2)

Substituting (B.2) into (B.1) and using (A.3), (A.5) and \(\bar{\epsilon} = \epsilon = 0\), we obtain

\[
\begin{align*}
\delta X &= \psi_\kappa, \\
\delta \psi_\kappa &= -i D_\kappa X - i \sigma X + \frac{A}{t} X, \\
\delta (\psi_\mu + i \epsilon^{\mu \nu} \psi_\nu) &= -i (D_\mu X + i \epsilon^{\mu \nu} D_\nu X) - i \epsilon \gamma^\mu \epsilon \sigma X + \frac{A}{t} \epsilon \gamma^\mu \epsilon X + \bar{\epsilon} \gamma^\mu \epsilon F_c, \\
\delta F_c &= \epsilon^{\mu \rho} \epsilon \gamma_\rho D_\mu \psi_\nu + i \sigma \epsilon \gamma^\mu \epsilon \psi_\mu + i \epsilon \gamma^\mu \epsilon \lambda_\mu X - \frac{A}{t} \epsilon \gamma^\mu \epsilon \psi_\mu.
\end{align*}
\]

(B.3)

We define new fields \(\psi\) belongs to zero-form, \(\chi_{\bar{z}}\) and \(Y_{\bar{z}}\) belong to \((0,1)\)-form by

\[
\begin{align*}
\psi &= \psi_\kappa, \\
\chi_{\bar{z}} &= \psi_1 + i \psi_2, \\
Y_{\bar{z}} &= -(F_c + i (D_1 + i D_2) X),
\end{align*}
\]

(B.4)
and use the relations
\begin{align*}
\epsilon \gamma^1 \epsilon &= -1, \quad \epsilon \gamma^2 \epsilon = -i, \quad \epsilon \gamma^3 \epsilon = 0, \\
\bar{\epsilon} \gamma^1 \bar{\epsilon} &= 1, \quad \bar{\epsilon} \gamma^2 \bar{\epsilon} = -i, \quad \bar{\epsilon} \gamma^3 \bar{\epsilon} = 0,
\end{align*}
we obtain the scalar BRST transformations in the new variables:
\begin{align*}
Q_X &= \psi, & Q_\psi &= -iD_\kappa X - i\sigma X + \Delta_l X, \\
Q_{\bar{Y}_\bar{z}} &= -i(D_\kappa + \sigma)\chi_{\bar{z}} + \frac{\Delta}{T} \chi_{\bar{z}}, & Q_{\chi_{\bar{z}}} &= Y_{\bar{z}}.
\end{align*}
(B.5)

As explained in the article, if we include the inhomogeneous term proportional to $\Delta/\ell$ into the eigenvalue of $\partial_\kappa$ ($\mathcal{L}_V$) by imposing the twisted boundary condition, the BRST transformations reduce to the compatible form with the vector multiplet
\begin{align*}
Q_X &= \psi, & Q_\psi &= -iD_\kappa X - i\sigma X, \\
Q_{\bar{Y}_\bar{z}} &= -i(D_\kappa + \sigma)\chi_{\bar{z}}, & Q_{\chi_{\bar{z}}} &= Y_{\bar{z}}.
\end{align*}
(B.7)
