ASYMPTOTIC STABILITY OF THE WONHAM FILTER: ERGODIC AND NON-ERGODIC SIGNALS

PETER BAXENDALE *, PAVEL CHIGANSKY †, AND ROBERT LIPTSER ‡

Abstract. Stability problem of the Wonham filter with respect to initial conditions is addressed. The case of ergodic signals is revisited in view of a gap in the classic work of H. Kunita (1971). We give new bounds for the exponential stability rates, which do not depend on the observations. In the non-ergodic case, the stability is implied by identifiability conditions, formulated explicitly in terms of the transition intensities matrix and the observation structure.

Key words. Nonlinear filtering, stability, Wonham filter

AMS subject classifications. 93E11, 60J57

1. Introduction. The optimal filtering estimate of a signal from the record of noisy observations is usually generated by a nonlinear recursive equation subject to the signal a priori distribution. If the latter is unknown and the filtering equation is initialized by an arbitrary initial distribution, the obtained estimate is suboptimal in general. From an applications point of view, it is important to know whether such estimate becomes close to the optimal one at least after enough time elapses. This property of filters to forget the initial conditions is far from being obvious and in fact generally remains an open and challenging problem.

In this paper, we consider the filtering setting for signals with a finite state space. Specifically, let $X = (X_t)_{t \geq 0}$ be a continuous time homogeneous Markov chain observed via

$$Y_t = \int_0^t h(X_s)ds + \sigma W_t$$

with the Wiener process $W = (W_t)_{t \geq 0}$, independent of $X$, some bounded function $h$, and $\sigma \neq 0$.

We assume that $X_t$ takes values in the finite alphabet $S = \{a_1, ..., a_n\}$ and admits several ergodic classes. Namely,

$$S = \{a_1^{1}, ..., a_1^{n_1}, ..., a_m^{1}, ..., a_m^{n_m}\},$$

where the subalphabets $S_1, ..., S_m$ are noncommunicating in the sense that for any $i \neq j$ and $t \geq s$

$$P(X_t ∈ S_j|X_s ∈ S_i) = 0.$$ 

So, unless $m = 1$, $X_t$ is a compound Markov chain with the transition intensities
matrix

\[
\Lambda = \begin{pmatrix}
\Lambda_1 & 0 & 0 \\
0 & \Lambda_2 & 0 \\
\ldots & \ldots & \ldots \\
0 & 0 & \Lambda_m
\end{pmatrix}
\]

of \( m \) ergodic classes and is not ergodic itself.

The filtering problem consists in computation of the conditional distribution,

\[
\pi_\nu^t(1) = P(X_\nu^t = a_1|Y_{0,t}^\nu), \ldots, \pi_\nu^n(n) = P(X_\nu^t = a_n|Y_{0,t}^\nu),
\]

where \( Y_{0,t}^\nu \) is the filtration, generated by \( \{ Y_s^\nu, 0 \leq s \leq t \} \) satisfying the usual conditions (henceforth, the superscript \( \nu \) is used to emphasize that the distribution of \( X_0 \) is \( \nu \)).

The vector-valued random process \( \pi_\nu^t \) with entries \( \pi_\nu^t(1), \ldots, \pi_\nu^n(n) \) is generated by the Wonham filter \( [45] \) (see also \([29, \text{Chap. 9}]\))

\[
\pi_0^\nu = \nu, \\
d\pi_t^\nu = \Lambda^*\pi_t^\nu dt + \sigma^{-2}\left( \text{diag}(\pi_t^\nu) - \pi_t^\nu(\pi_t^\nu)^* \right) h(dY_t^\nu - h^*\pi_t^\nu dt),
\]

where \( \text{diag}(x) \) is the scalar matrix with the diagonal \( x \in \mathbb{R}^n \), \( h \) is the column vector with entries \( h(a_1), \ldots, h(a_n) \), and \(^*\) is the transposition symbol. If \( \nu \) is unknown and some other distribution \( \beta \) (on \( \mathbb{S} \)) is used to initialize the filter, the “wrong” conditional distribution \( \pi_\beta^t \) is obtained:

\[
\pi_0^\beta = \beta, \\
d\pi_t^\beta = \Lambda^*\pi_t^\beta dt + \sigma^{-2}\left( \text{diag}(\pi_t^\beta) - \pi_t^\beta(\pi_t^\beta)^* \right) h(dY_t^\beta - h^*\pi_t^\beta dt).
\]

According to the intuitive notion of stability, given at the beginning of this section, the filter defined in (1.5) is said to be asymptotically stable if

\[
\lim_{t \to \infty} E \| \pi_t^\nu - \pi_t^\beta \| = 0,
\]

where \( \| \cdot \| \) is the total variation norm.

If the state space of the Markov chain \( X \) consists of one ergodic class \((m = 1)\), our setting is in the framework studied by Ocone and Pardoux \([35]\). In this case, there exists the unique invariant distribution \( \mu \), so that

\[
\lim_{t \to \infty} \| S_t \gamma - \mu \| = 0,
\]

where \( S_t \) is the semigroup corresponding to \( X \) and \( \gamma \) is an arbitrary probability distribution on \( \mathbb{S} \). Moreover

\[
\lim_{t \to \infty} \int_\mathbb{S} |S_t f(x) - \mu(f)| d\mu(x) = 0
\]

holds for any bounded \( f : \mathbb{S} \to \mathbb{R} \). So, it may seem that it remains only to assume

\[
\nu \ll \beta
\]

and allude to \([35]\). However, the proof of (1.6) given in \([35]\) uses as its central argument the uniqueness theorem for the stationary measure of the filtering process \( \pi_t^\nu \) which
appeared in the work of H. Kunita [23]. Unfortunately, the proof of this theorem (Theorem 3.3 in [23]) contains a serious gap, as elaborated in the next section.

Different approach to the stability analysis of the filters for ergodic signals was initiated by Delyon and Zeitouni [20]. The authors studied the top Lyapunov exponent of the filtering equation

\[ \gamma_\sigma(\beta', \beta'') = \lim_{t \to \infty} \frac{1}{t} \log \| \pi_{t\beta'} - \pi_{t\beta''} \|, \]

\( \beta' \) and \( \beta'' \) distributions on \( S \), and show that \( \gamma_\sigma(\beta', \beta'') < 0 \) when \( \Lambda \) and \( h \) satisfy certain conditions. Moreover the filter is found to be stable in the low signal-to-noise regime:

\[ \lim_{\sigma \to \infty} \gamma_\sigma(\beta', \beta'') \leq \Re[\lambda_{\text{max}}(\Lambda)] \] with \( \lambda_{\text{max}}(\Lambda) \) being the eigenvalue of \( \Lambda \) with the largest nonzero real part.

These results were further extended by Atar and Zeitouni [3], where it is shown that uniformly in \( \sigma > 0 \) and \( h \)

\[ (1.10) \]

and the high signal-to-noise asymptotics are obtained:

\[ \lim_{\sigma \to 0} \sigma^2 \gamma_\sigma \leq - \frac{1}{2} \sum_{i=1}^{d} \mu_i \min_{j \neq i} [h(a_i) - h(a_j)]^2 \]

\[ \lim_{\sigma \to 0} \sigma^2 \gamma_\sigma \geq - \frac{1}{2} \sum_{i=1}^{d} \mu_i \sum_{j=1}^{d} [h(a_i) - h(a_j)]^2 \]

where \( \mu \) is the ergodic measure of \( X \).

The method in [3] (and its full development in [2]) does not rely on [23] and is based on the analysis of the Zakai equation, corresponding to (1.4) (see (5.2) below). The analysis is carried out by means of the Hilbert projective metric and the Birkhoff inequality, etc.; see section 5 for more details. This approach proved out its efficiency in several filtering scenarios (see [1], [9], [11]).

Other results and methods related to the filtering stability can be found in [4], [10], [12], [13], [14], [15], [17], [18], [16], [20], [19], [20], [27], [28], [29], [37]. The linear Kalman–Bucy case, being the most understood, is extensively treated by several authors: [5], [32], [33], [20], [35], [28], [30] (sections 14.6 and 16.2).

In the present paper, we consider both ergodic and non-ergodic signals. Applying the technique from Atar and Zeitouni, [2], we show that in the ergodic case the asymptotic stability holds true without any additional assumptions. In other words, the conclusion of H. Kunita [23] is valid in the specific case under consideration.

In view of the counterexample given in section 3, it is clear that in general \( \gamma_\sigma \) may vanish at \( \sigma = 0 \). So, it is interesting to find out which ergodic properties of the signal are inherited by the filter regardless of the specific observation structure. In this connection we prove the inequality

\[ \lim_{t \to \infty} \frac{1}{t} \log \| \pi_{t\beta'} - \pi_{t\beta''} \| \leq - \sum_{r=1}^{n} \mu_r \min_{i \neq r} \lambda_{ri}. \]

Since \( \mu \) is the positive measure on \( S \), unlike (1.10), this bound remains negative if at least one row of \( \Lambda \) has all nonzero entries.
Also we give the nonasymptotic bound (compare with (1.10))
\[
\|\pi_t^\nu - \pi_t^\beta\| \leq C \exp \left(-2t \min_{\nu \neq q} \sqrt{\frac{\lambda_{pq} \lambda_{qp}}{\lambda_{qq}}}ight)
\]
with some positive constant \(C\) depending on \(\nu\) and \(\beta\) only.

For the discrete time case, related results can be found in Del Moral and Guionnet [18] and Le Gland and Mevel [25]. For example, in [25] the positiveness assumption for all transition probabilities is relaxed under certain constraints on the observation process noise density.

In the case of nonergodic signal, \(m>1\), we show that the filtering stability holds true if the ergodic classes can be identified via observations and the filter matched to each class is stable. We formulate explicit sufficient identifiability conditions in terms of \(\Lambda\) and \(\pi\).

The paper is organized as follows. In section 2, we introduce the necessary notations and clarify the role of condition \(\nu \ll \beta\) in the filtering stability (Proposition 2.1). This section also gives a link to the gap in Kunita’s proof [23], while in section 3 the filtering setting is described for which the stability fails and the gap becomes evident.

The main results are formulated in section 4 and proved in sections 5 and 6.

2. Preliminaries and connection to the gap in [23].

2.1. Notations. Throughout, \(\nu \ll \beta\) is assumed.

In order to explain our approach, let us consider a general setting when \((X,Y)\) is Markov process with paths from the Skorokhod space \(\mathbb{D} = \mathbb{D}_{[0,\infty)}(\mathbb{R}^2)\) of right continuous functions having limits to the left functions. Moreover, the signal component \(X\) is Markov process itself.

We introduce a measurable space \((\mathbb{D}, \mathcal{D})\), where \(\mathcal{D} = \sigma\{(x_s,y_s), s \geq 0\}\) is the Borel \(\sigma\)-algebra on \(\mathbb{D}\). Let \(D = (\mathcal{D}_t)_{t \geq 0}\) be the filtration of \(\mathcal{D}_t = \sigma\{(x_s,y_s), s \leq t\}\) and let \(D^\nu = (\mathcal{D}^\nu_t)_{t \geq 0}\) be the filtration of \(\mathcal{D}^\nu_t = \sigma\{y_s, s \leq t\}\).

As before, we write \((X^\nu_t, Y^\nu_t)\) and \((X^\beta_t, Y^\beta_t)\), when the distribution of \(X_0\) is \(\nu\) or \(\beta\) respectively, meaning that both pairs are defined on the same probability space, have the same transition semigroup, but different initial distributions.

For a bounded measurable function \(f\), we introduce \(\pi_t^\nu(f) := E(f(X^\nu_t)|\mathcal{D}^\nu_{0,t})\) and \(\pi_t^\beta(f) := E(f(X^\beta_t)|\mathcal{D}^\beta_{0,t})\). Since \(\pi_t^\nu(f)\) and \(\pi_t^\beta(f)\) are \(\mathcal{D}^\nu_{0,t}\) and \(\mathcal{D}^\beta_{0,t}\) measurable random variables respectively, it is convenient to identify \(\pi_t^\nu(f)\) and \(\pi_t^\beta(f)\) with some \(\mathcal{D}^\nu_t\)-measurable functionals of trajectories \(Y^\nu_{0,t} = \{Y^\nu_s, s \leq t\}\) and \(Y^\beta_{0,t} = \{Y^\beta_s, s \leq t\}\).

For this purpose, let \(Q^\nu\) and \(Q^\beta\) denote the distributions of \((X^\nu,Y^\nu)\) and \((X^\beta,Y^\beta)\) on \((\mathbb{D}, \mathcal{D})\) respectively and \(Q^\nu_t\) and \(Q^\beta_t\) be their restrictions on \([0,t]\), so that \(Q^\nu_0\), \(Q^\beta_0\) are the distributions of \((X^\nu_0,Y^\nu_0),(X^\beta_0,Y^\beta_0)\). We also assume that

\[
\frac{dQ^\nu_0}{dQ^\beta_0}(x,y) = \frac{d\nu}{d\beta}(x_0).
\]

Since \((X^\nu_t,Y^\nu_t)\) and \((X^\beta_t,Y^\beta_t)\) have the same transition law, we have \(Q^\nu \ll Q^\beta\) with

\[
\frac{dQ^\nu}{dQ^\beta}(x,y) = \frac{d\nu}{d\beta}(x_0).
\]

Without loss of generality, we assume that the filtrations \(D\) and \(D^\nu\) satisfy the general conditions with respect to \((Q^\nu + Q^\beta)/2\).
For fixed \( t \), let \( H_t^\beta(y) \) be \( \mathcal{D}_t \)-measurable functional so that \( H_t^\beta(Y^\beta) = \pi_t^\beta(f) \), a.s. Moreover, due to \( Q^\nu \ll Q^\beta \), a version of \( H_t^\beta(y) \) can be chosen such that the random variable \( H_t^\beta(Y^\nu) \) is well defined. Then, we identify \( \pi_t^{\beta\nu}(f) \) with \( H_t^\beta(Y^\nu) \).

We do not assume that \( \beta \ll \nu \) (and thus \( Q^\beta \not\ll Q^\nu \)), so this construction fails for \( \pi_t^{\beta\nu}(f) \). Nevertheless, a version of \( H_t^\beta(y) \) can be chosen such that \( H_t^\beta(Y^\nu) = \pi_t^{\beta\nu}(f) \) a.s. and used for the definition of \( \pi_t^{\beta\nu}(f) \). Indeed, let \( Q^\beta \) and \( Q^\nu \) be the distributions of \( Y^\nu \) and \( Y^\beta \) respectively, i.e., the marginal distributions of \( Q^\beta \) and \( Q^\nu \). Obviously, \( Q^\beta \not\ll Q^\nu \) as well as \( Q^\nu \not\ll Q^\beta \); the restrictions of \( Q^\beta \) and \( Q^\nu \) on the interval \([0,t]\).

Moreover, \( \frac{dQ^\nu}{dQ^\beta}(Y^\beta) = E\left(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathcal{F}^\beta_{[0,t]}\right) \). Now define

\[
\pi_t^{\nu\beta}(f) := H_t^\nu(Y^\beta)I\left(\frac{dQ^\nu}{dQ^\beta}(Y^\beta) > 0\right).
\]

We introduce the decreasing filtration \( \mathcal{F}_{[t,\infty)} = \sigma\{X^\beta_s, s \geq t\} \), the tail \( \sigma \)-algebra

(2.2)
\[
\mathcal{F}(X^\beta) = \bigcap_{t \geq 0} \mathcal{F}_{[t,\infty)},
\]

and \( \sigma \)-algebras \( \mathcal{F}_t^\beta = \sigma\{X^\beta_t\}, \quad \mathcal{F}_{[0,\infty)}^\beta = \bigvee_{t \geq 0} \mathcal{F}_{[0,t]}^\beta \).

Set

(2.3)
\[
\pi_t^{\beta\nu}(f) = E\left(f(X_t^\beta)|\mathcal{F}_{[0,t]}^\beta \lor \mathcal{F}_0^\beta\right).
\]

2.2. Filter stability. For bounded and measurable \( f \), the estimate \( \pi_t^{\nu}(f) \) is asymptotically stable with respect to \( \beta \), if

(2.4)
\[
\lim_{t \to \infty} E|\pi_t^{\nu}(f) - \pi_t^{\beta\nu}(f)| = 0.
\]

Note that, when the signal process takes values in a finite alphabet and \( 2.4 \) holds for any bounded \( f \), then \( 2.2 \) and \( 1.4 \) are equivalent.

We establish below that \( 2.4 \) holds, if for large values of \( t \) the additional measurement \( X_t^\beta \) is useless for estimation of \( f(X_t^\beta) \) via \( Y_{[0,t]}^\beta \) or, analogously, if the additional measurement \( X_t^\beta \) is useless for estimation of \( \frac{d\nu}{d\beta}(X_0^\beta) \) via \( Y_{[0,\infty)}^\beta \).

**Proposition 2.1.** Assume \( \nu \ll \beta \). Then, any of the conditions

1. (2.5)
\[
\lim_{t \to \infty} E|\pi_t^{\beta}(f) - \pi_t^{\beta\nu}(f)| = 0,
\]

2. (2.6)
\[
E\left(\frac{d\nu}{d\beta}(X_0^\beta)|\mathcal{F}_{[0,\infty)}^\beta\right) = \lim_{t \to \infty} E\left(\frac{d\nu}{d\beta}(X_t^\beta)|\mathcal{F}_{[0,\infty)}^\beta \lor \mathcal{F}_t^\beta\right),
\]

provides \( 2.4 \).

**Proof.** Let us first show that, under \( \nu \ll \beta \), for any bounded \( f \)

(2.7)
\[
E|\pi_t^{\beta\nu}(f) - \pi_t^{\nu}(f)|
\]
\[
= E\left(E\left(\frac{d\nu}{d\beta}(X_0^\beta)|\mathcal{F}_{[0,t]}^\beta\right)E\left(f(X_t^\beta)|\mathcal{F}_{[0,t]}^\beta\right) - E\left(E\left(\frac{d\nu}{d\beta}(X_0^\beta)\right)f(X_t^\beta)|\mathcal{F}_{[0,t]}^\beta\right)\right).
\]
Write
\[ E|\pi_t^{\beta\nu}(f) - \pi_t^\nu(f)| = E \left( \frac{d\nu}{d\beta}(X_0^\beta) | \pi_t^\beta(f) - \pi_t^{\nu\beta}(f) \right) \]
\[ = EE \left( \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \right) | \pi_t^\beta(f) - \pi_t^{\nu\beta}(f)| = E \left( \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \right) \left| \pi_t^\beta(f) - \pi_t^{\nu\beta}(f) \right| \]
\[ = E \left| \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \left( f(X_t^\beta)|_{[0,1]} \right) - E \left( \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \left( \pi_t^{\nu\beta}(f) \right) \right. \right| \]

So, it remains to show
\[ (2.8) \quad E \left( \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \pi_t^{\nu\beta}(f) \right) = E \left( \frac{d\nu}{d\beta}(X_0^\beta) f(X_t^\beta)|_{[0,1]} \right). \]

With $\mathcal{D}_t^\nu$-measurable and bounded function $\Psi_t(y)$ we get
\[ E \left\{ \Psi_t(Y^\beta) E \left( \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \pi_t^{\nu\beta}(f) \right) \right\} = E \left\{ \Psi_t(Y^\beta) \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \pi_t^{\nu\beta}(f) \right\} \]
\[ = E \left( \Psi_t(Y^\nu) \pi_t^\nu(f) \right) = E \left( \Psi_t(Y^\nu) f(X_t^\nu) \right) = E \left( \Psi_t(Y^\nu) \frac{d\nu}{d\beta}(X_0^\beta)f(X_t^\nu) \right), \]
and notice that (2.8) is valid by the arbitrariness of $\Psi_t$.

**The proof of (2.8)⇒(2.4).** Using (2.7) and
\[ E \left( \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \pi_t^{\nu\beta}(f) \right) = E \left( \frac{d\nu}{d\beta}(X_0^\beta) f(X_t^\beta)|_{[0,1]} \right), \]
we derive
\[ E \left| \pi_t^{\beta\nu}(f) - \pi_t^\nu(f) \right| = E \left| E \left( \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \pi_t^\beta(f) - E \left( \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \pi_t^{\nu\beta}(f) \right) \right) \right| \]
\[ = E \left| E \left( \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \pi_t^\beta(f) - \pi_t^{\nu\beta}(f) \right) \right| \leq E \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \left| \pi_t^{\beta\nu}(f) - \pi_t^\nu(f) \right|, \]
where the Jensen inequality has been used. Let for definiteness $|f| \leq K$ with some constant $K$. Then $\pi_t^\beta(f)$, $\pi_t^{\nu\beta}(f)$ can also be chosen such that $|\pi_t^\beta(f)|$ and $|\pi_t^{\nu\beta}(f)|$ are bounded by $K$. Hence, for any $C > 0$, we have
\[ E \left| \pi_t^{\beta\nu}(f) - \pi_t^\nu(f) \right| \leq CE \left| \pi_t^\beta(f) - \pi_t^{\nu\beta}(f) \right| + 2KP \left( \frac{d\nu}{d\beta}(X_0^\beta) > C \right). \]

Therefore, \[ \lim_{t \to \infty} E \left| \pi_t^{\beta\nu}(f) - \pi_t^\nu(f) \right| \leq 2KP \left( \frac{d\nu}{d\beta}(X_0^\beta) > C \right) \] and by the Chebyshev inequality $P \left( \frac{d\nu}{d\beta}(X_0^\beta) > C \right) \leq C^{-1} \to 0$, $C \to \infty$.

**The proof of (2.4)⇒(2.8).** By (2.7)
\[ E \left| \pi_t^{\beta\nu}(f) - \pi_t^\nu(f) \right| \]
\[ = E \left| \left( f(X_t^\beta) \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \pi_t^\beta(f) \right) - E \left( f(X_t^\beta) \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \pi_t^{\nu\beta}(f) \right) \right| \]
Notice also
\[ E \left( f(X_t^\beta) \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \pi_t^{\nu\beta}(f) \right) = E \left( f(X_t^\beta) \frac{d\nu}{d\beta}(X_0^\beta)|_{[0,1]} \right), \]
Since $|f| \leq K$, by the Jensen inequality we have

\begin{equation}
(2.9) \quad E[\pi_t^{\beta'}(f) - \pi_t^{\beta''}(f)] \leq KE\left[ E\left( \frac{d\nu}{d\beta} (X_0^\beta) \mid \mathcal{Y}_0^\beta \right) - E\left( \frac{d\nu}{d\beta} (X_0^\beta) \mid \mathcal{Y}_0^\beta \right) \right].
\end{equation}

Both random processes $E\left( \frac{d\nu}{d\beta} (X_0^\beta) \mid \mathcal{Y}_0^\beta \right)$ and $E\left( \frac{d\nu}{d\beta} (X_0^\beta) \mid \mathcal{Y}_0^\beta \right)$ are uniformly integrable forward and backward martingales with respect to the filtrations $\mathcal{Y}_0^\beta \mid \tau \geq 0$ and $\mathcal{Y}_0^\beta \mid \tau \sim 0$. Therefore, they admit limits a.s. in $t \to \infty$:

\begin{equation}
\lim_{t \to \infty} E\left( \frac{d\nu}{d\beta} (X_0^\beta) \mid \mathcal{Y}_0^\beta \right) = 0.
\end{equation}

We show also that

\begin{equation}
(2.10) \quad \lim_{t \to \infty} E\left[ E\left( \frac{d\nu}{d\beta} (X_0^\beta) \mid \mathcal{Y}_0^\beta \right) - E\left( \frac{d\nu}{d\beta} (X_0^\beta) \mid \mathcal{Y}_0^\beta \right) \right] = 0.
\end{equation}

Denote by $\alpha_t$ any of $E\left( \frac{d\nu}{d\beta} (X_0^\beta) \mid \mathcal{Y}_0^\beta \right)$ and $E\left( \frac{d\nu}{d\beta} (X_0^\beta) \mid \mathcal{Y}_0^\beta \right)$ and

$$
\alpha_\infty = \lim_{t \to \infty} \alpha_t.
$$

It is clear that (2.10) holds true, if $\lim_{t \to \infty} E[\alpha_t - \alpha_\infty] = 0$. Since $\lim_{t \to \infty} \alpha_t = \alpha_\infty$, $\alpha_t \geq 0$ and $E\alpha_t = E\alpha_\infty = 1$, by the Scheffe theorem we get the desired property.

Thus the right hand side of (2.6) converges to zero and the result follows.

### 2.3. Connection to the gap in [23]

In [23], H. Kunita studies ergodic properties of the filtering process $\pi_t$. He considers $\pi_t$ as a Markov process with values in the space of probability measures and claims (in Theorem 3.3) that there exists the unique invariant measure being “limit point” of marginal distributions of $\pi_t$, $t \nearrow \infty$. As was later shown in [24], this result is the key to the stability analysis under $L_2$.

Below we demonstrate that the main argument, used in the proof of Theorem 3.3 of [23], cannot be taken for granted. We discuss this issue in the context of Proposition 2.1. Suppose the Markov process $X$ is ergodic in the sense of [14] and [13]. It is well known that its tail $\sigma$-algebra $\mathcal{T}(X^\beta)$ (see [24] for definition) is empty almost surely. It is very tempting in this case to change the order of intersection and supremum as follows:

\begin{equation}
(2.11) \quad \bigcap_{t \geq 0} \mathcal{Y}_0^\beta \vee \mathcal{T}^\beta_{[t, \infty)} = \mathcal{Y}_0^\beta \vee \mathcal{T}(X^\beta), \quad a.s.
\end{equation}

Then, the right-hand side of (2.6) is transformed to

$$
\lim_{t \to \infty} E\left( \frac{d\nu}{d\beta} (X_0^\beta) \mid \mathcal{Y}_0^\beta \vee \mathcal{T}^\beta_{[t, \infty)} \right) = E\left( \frac{d\nu}{d\beta} (X_0^\beta) \mid \mathcal{Y}_0^\beta \vee \mathcal{T}(X^\beta) \right) = E\left( \frac{d\nu}{d\beta} (X_0^\beta) \mid \mathcal{Y}_0^\beta \right)
$$

\footnote{The notations of this paper are used here.}
and (2.6) would be correct, regardless (!) of any other ingredients of the problem (e.g., with $\sigma = 0$ in (1.1)).

In [23], the relation of (2.11) type plays the key role in verification of the uniqueness for the invariant measure corresponding to $\pi_\nu^\nu$, $t \geq 0$. However, the validity of (2.11) is far from being obvious. According to Williams [44], it ”...tripped up even Kolmogorov and Wiener” (see Y. Sinai [39, p. 837] for some details). The reader can find a discussion concerning (2.11) in Weizsäcker [43]; unfortunately, the counterexample there is incorrect. A proper counterexample to (2.11) is given in Exercise 4.12 in Williams [44], which, however, seems somewhat artificial in the filtering context. It turns out that the example, considered by Delyon and Zeitouni in [20] (see [22] by Kaijser for its earlier discrete-time version), is nothing but another case when (2.11) fails.

For the reader convenience, we give below a detailed analysis of this example.

It is important to note that the counterexamples mentioned above do not fit exactly to the setup, considered by Kunita. They merely indicate that (2.11) is not evident and so the claim of Theorem 3.3 in [23] remains a conjecture.

Generally, the stability of nonlinear filters for ergodic Markov processes remains an open problem, and some results [24], [10], [11], [6], [8], [7], [35] based on [23] have to be revised.

3. Counterexample. Below we give a detailed discussion of one counterexample to (2.11). Consider Markov process $X$ with values in $S = \{1, 2, 3, 4\}$, with the initial distribution $\nu$ and the transition intensities matrix

$$
\Lambda = \begin{pmatrix}
-1 & 1 & 0 & 0 \\
0 & -1 & 1 & 0 \\
0 & 0 & -1 & 1 \\
1 & 0 & 0 & -1
\end{pmatrix}.
$$

All states of $\Lambda$ communicate and so, $X$ is an ergodic Markov process (see e.g., [34]) with the unique invariant measure $\mu = (1/4, 1/4, 1/4, 1/4)$. Let $h(x) = I(x = 1) + I(x = 3)$, that is,

$$Y_t = \int_0^t [I(X_s = 2) + I(X_s = 3)] ds + \sigma W_t.
$$

By Theorem 4.1 below, the filter is stable in this case for any $\sigma > 0$.

3.1. Noiseless observation. Consider the case $\sigma = 0$.

It will be convenient to redefine the observation process as follows:

$$Y_t = [I(X_t = 1) + I(X_t = 3)].$$

We assume $\nu \ll \beta$ and notice that (2.11) holds true. We omit the superscripts $\nu$ and $\beta$, when the initial condition does not play a significant role. Since $X$ is ergodic Markov process, satisfying (1.8), $\mathcal{F}(X) = (\Omega, \emptyset)$, a.s.

**Proposition 3.1.**

$$\bigcap_{t \geq 0} \left( \mathcal{F}_{[0, \infty)} \cup \mathcal{F}_{[t, \infty)} \right) \supseteq \mathcal{F}_{[0, \infty)}, \text{ a.s.}$$
Proof. It suffices to show that \( X_0 \) is \( \cap_{t \geq 0} \left( \mathcal{Y}_{(0,\infty)} \cup \mathcal{Y}_{[t,\infty)} \right) \)-measurable random variable and at the same time \( X_0 \notin \mathcal{Y}_{(0,\infty)} \).

The structure of matrix \( \Lambda \) admits only cyclic transitions in the following order

\[
\cdots \to \{3\} \to \{4\} \to \{1\} \to \{2\} \to \{3\} \to \cdots
\]

So, since \( Y \) and \( X \) jump simultaneously, \( X_0 \) can be recovered exactly from the trajectory \( Y_s, s \leq t \) and \( X_t \) for any \( t > 0 \), i.e., \( X_0 \) is \( \mathcal{Y}_{(t,\infty)} \)-measurable. Owing to \( \mathcal{Y}_{(t,\infty)} \subset \mathcal{X}_{(t,\infty)} \cup \mathcal{Y}_{(0,\infty)} \), \( X_0 \) is measurable with respect to

\[
\cap_{t \geq 0} \left( \mathcal{Y}_{(0,\infty)} \cup \mathcal{Y}_{[t,\infty)} \right).
\]

Denote by \( (\tau_i)_{i \geq 1} \) the time moments where \( Y \) jumps. It is not hard to check that \( (\tau_i)_{i \geq 0} \) is independent of \((X_0, Y_0)\) and moreover

\[
\mathcal{Y}_{[0,t]} = \bigvee_{i \geq 0} \sigma\{\tau_i \leq t\} \cup \sigma\{Y_0\}.
\]

Thus for any \( t \geq 0 \)

\[
P(X_0 = 1|\mathcal{Y}_{[0,t]}) = P \left( X_0 = 1 \big| \bigvee_{i \geq 0} \sigma\{\tau_i \leq t\} \cup \sigma\{Y_0\} \right) = P(X_0 = 1|Y_0) = \frac{\nu_1}{\nu_1 + \nu_3} Y_0.
\]

Since \( \nu_1 > 0 \) is valid for any \( t \geq 0 \), we conclude that

\[
P(X_0 = 1|\mathcal{Y}_{(0,\infty)}) = \frac{\nu_1}{\nu_1 + \nu_3} Y_0.
\]

Obviously \( I(X_0 = 1) \neq \frac{\nu_1}{\nu_1 + \nu_3} Y_0 \) and thus \( X_0 \) is not \( \mathcal{Y}_{(0,\infty)} \)-measurable. \( \square \)

3.2. Invariant measures of \( \pi_t \) and the filter instability. Since \( I_t(2) + I_t(4) = 1 - Y_t \) and \( I_t(1) + I_t(3) = Y_t \), only \( I_t(1) \) and \( I_t(2) \) have to be filtered while \( \pi_t(3) = Y_t - \pi_t(1) \) and \( \pi_t(4) = (1 - Y_t) - \pi_t(2) \). The derivation of the filtering equations is sketched in the appendix.

\textbf{Proposition 3.2.} The optimal filtering estimate satisfies

\[
d\pi_t(1) = (1 - \pi_t(2))(1 - Y_t) dY_t + \pi_t(1)Y_t dY_t,
\]

\[
d\pi_t(2) = -\pi_t(2)(1 - Y_t) dY_t - \pi_t(1)Y_t dY_t
\]

subject to \( \pi_0(1) = \frac{\nu_1}{\nu_1 + \nu_3} Y_0 \), \( \pi_0(2) = \frac{\nu_2}{\nu_2 + \nu_4}(1 - Y_0) \).

Let us examine the behavior of the filter from Proposition 3.2. A pair of typical trajectories are given in Table 3.1 (for \( Y_0 = 1 \)) and Table 3.2 (for \( Y_0 = 0 \)).

It is not hard to see that \( Y \) is itself Markov chain with values in \( \{0, 1\} \) and the transition intensities matrix \( \begin{pmatrix} -1 & 1 \\ 1 & -1 \end{pmatrix} \) and thus its invariant measure is \( \mu' = (1/2, 1/2) \). Hence, the invariant measure \( \Phi \) of the filtering process \((\pi_t(1), \pi_t(2))\) is concentrated on eight vectors

\[
\phi_1 = \begin{pmatrix} \frac{\nu_2}{\nu_2 + \nu_4} \\ 0 \end{pmatrix}, \quad \phi_2 = \begin{pmatrix} 0 \\ \frac{\nu_1}{\nu_1 + \nu_3} \end{pmatrix}, \quad \phi_3 = \begin{pmatrix} \frac{\nu_3}{\nu_1 + \nu_3} \\ 0 \end{pmatrix}, \quad \phi_4 = \begin{pmatrix} 0 \\ \frac{\nu_2}{\nu_2 + \nu_4} \end{pmatrix},
\]

\[
\phi_5 = \begin{pmatrix} \frac{\nu_2}{\nu_2 + \nu_4} \\ 0 \end{pmatrix}, \quad \phi_6 = \begin{pmatrix} 0 \\ \frac{\nu_1}{\nu_1 + \nu_3} \end{pmatrix}, \quad \phi_7 = \begin{pmatrix} \frac{\nu_3}{\nu_1 + \nu_3} \\ 0 \end{pmatrix}, \quad \phi_8 = \begin{pmatrix} 0 \\ \frac{\nu_2}{\nu_2 + \nu_4} \end{pmatrix}.
\]
Table 3.1  
Typical trajectory of $\pi_t$ for $Y_0 = 1$.

| $t$ | $(0, \tau_1)$ | $(\tau_1, \tau_2)$ | $(\tau_2, \tau_3)$ | $(\tau_3, \tau_4)$ | $(\tau_4, \tau_5)$ | ... |
|-----|----------------|-------------------|-------------------|-------------------|-------------------|-----|
| $Y_t$ | 1 | 0 | 1 | 0 | 1 | ... |
| $\pi_t(1)$ | $\nu_1 + \nu_3$ | 0 | $\nu_1 + \nu_4$ | 0 | $\nu_1 + \nu_4$ | ... |
| $\pi_t(2)$ | 0 | $\nu_1 + \nu_3$ | 0 | $\nu_1 + \nu_4$ | 0 | ... |

Table 3.2  
Typical trajectory of $\pi_t$ for $Y_0 = 0$.

| $t$ | $(0, \tau_1)$ | $(\tau_1, \tau_2)$ | $(\tau_2, \tau_3)$ | $(\tau_3, \tau_4)$ | $(\tau_4, \tau_5)$ | ... |
|-----|----------------|-------------------|-------------------|-------------------|-------------------|-----|
| $Y_t$ | 0 | 1 | 1 | 0 | 0 | ... |
| $\pi_t(1)$ | 0 | $\nu_2 + \nu_4$ | 0 | $\nu_2 + \nu_4$ | 0 | ... |
| $\pi_t(2)$ | $\nu_2 + \nu_4$ | 0 | $\nu_2 + \nu_4$ | 0 | $\nu_2 + \nu_4$ | ... |

with

$$\Phi(\phi_i) = (\nu_1 + \nu_3)/4, \quad i = 1, 2, 3, 4,$$

$$\Phi(\phi_i) = (\nu_2 + \nu_4)/4, \quad i = 5, 6, 7, 8,$$

and, consequently, $\Phi$ is not unique. Moreover, the optimal filter is not stable in the sense [14]. In fact, for different initial conditions, the filtering distribution $\pi_t, t > 0$ can “sit” on different vectors!

4. Main results.

4.1. Ergodic case. Markov chain $X$ is ergodic, if and only if all entries of its transition intensities matrix $\Lambda$ communicate, i.e., for any pair of indices $i$ and $j$, a string of indices $\{\ell_1, \ldots, \ell_m\}$ can be found so that $\lambda_{i\ell_1} \lambda_{\ell_1 \ell_2} \ldots \lambda_{\ell_m j} \neq 0$ (see, e.g., [34]). In this case, the distribution of $X_t$ converges to the positive invariant distribution $\mu$ being the unique solution of $\Lambda^* \mu = 0$ in the class of vectors with positive entries the sum of which is equal to one.

Theorem 4.1. If all states of $\Lambda$ communicate, then there exists a positive constant $c$ such for any $\nu$ and $\beta$

$$\lim_{t \to \infty} \frac{1}{t} \log \| \pi_t^{\beta \nu} - \pi_t^\nu \| < -c, \quad a.s.$$

Remark 1. Clearly, Theorem 4.1 provides [14]. Also it allows to conclude that $\lim_{t \to \infty} \| \pi_t^{\beta \nu} - \pi_t^\nu \| = 0$, $a.s.$ for $\beta$ concentrated in a single state of $S$. Then, in particular, we have

$$\lim_{t \to \infty} \| \pi_t^\nu - \pi_t^\mu \| = 0$$

which is the main argument in the proof of existence of the unique invariant measure for the process $(\pi_t)_{t \geq 0}$. This fact corroborates Kunita’s result from [23] in the finite state space setup of Theorem 4.1.

Actually, Theorem 4.1 verifies the logarithmic rate in $t \to \infty$ which is in general a function of $\Lambda$, $h$ and $\sigma$. However stronger assumptions on $\Lambda$ guarantee exponential or logarithmic rates, regardless of $h$ and $\sigma$ ($\sigma$ is only required to be nonzero).
Theorem 4.2. Assume all states of $\Lambda$ communicate. Then

$$\lim_{t \to \infty} \frac{1}{t} \log \|\pi_t^{\beta \nu} - \pi_t^{\nu}\| \leq - \sum_{r=1}^{n} \mu_r \min_{i \neq r} \lambda_{ri}. \quad (4.1)$$

Remark 2. The bound $(4.1)$ is negative if at least one row of $\Lambda$ has all nonzero entries.

Theorem 4.3. Assume all entries of $\Lambda$ are nonzero.

1. If $\nu \ll \beta$, then

$$E \|\pi_t^{\beta \nu} - \pi_t^{\nu}\| \leq n \sum_{j=1}^{n} \frac{d\nu}{d\beta}(a_j) \exp \left( -2t \min_{p \neq q} \sqrt{\lambda_{pq} \lambda_{qp}} \right), \quad t > 0. \quad (4.2)$$

2. If $\nu \sim \beta$, then

$$\|\pi_t^{\beta \nu} - \pi_t^{\nu}\| \leq n^2 \max_{j=1}^{n} \frac{d\nu}{d\beta}(a_j) \max_{j=1}^{n} \frac{d\beta}{d\nu}(a_j) \exp \left( -2t \min_{p \neq q} \sqrt{\lambda_{pq} \lambda_{qp}} \right), \quad t > 0. \quad (4.3)$$

4.2. Nonergodic case. Let $m \geq 2$ and $\Lambda$ be given in $(1.3)$. If $X_0 \in S_j$, then $X$ is Markov process with values in $S_j$ with transition intensities matrix $\Lambda_j$. We denote this process by $X^j$. In addition to $h$, introduce column vectors $h_j, j = 1, \ldots, m$ with entries $h_j(a_{ij})$ respectively.

Theorem 4.4. Assume the following.

A-1. For any $j$, all states of $\Lambda_j$ communicate.

A-2. For each $j, k$ with $j \neq k$ either

$$h_j^* \mu_j \neq h_k^* \mu_k$$

or

$$h_j^* \text{diag}(\mu^j) \Lambda_j h_j \neq h_k^* \text{diag}(\mu^k) \Lambda_k h_k, \quad \text{for some } 0 \leq q \leq n_j + n_k - 1.$$  

Then the asymptotic stability $(1.6)$ holds true.

The condition $[A-1]$ is inherited from Theorem 4.1 to ensure the stability within each ergodic class, while under $[A-2]$, $\beta_{(0, \infty)}$ completely identifies the class in which $X$ actually resides.

5. Proofs for the ergodic case. Recall that under $m = 1$, $X$ is a homogeneous ergodic Markov chain with values in the finite alphabet $S = \{a_1, \ldots, a_n\}$ with the transition intensities matrix $\Lambda$. The unique invariant measure $\mu = (\mu_1, \ldots, \mu_n)$ is the positive distribution on $S$. Let $\nu$ be the distribution of $X_0$ and $\beta$ a probability measure on $S$. The observation process $Y$ is defined in $(1.1)$. Recall that the entries of $\pi_t^\nu$ and $\pi_t^{\beta \nu}$ are the true and “wrong” conditional probabilities respectively as defined in the introduction.

5.1. The proof of Theorem 4.1. We use the method proposed by Atar and Zeitouni in [2], which is elaborated for the considered filtering setup for reader convenience.

Recall the following facts from the theory of nonnegative matrices. For a pair $(p, q)$ of nonnegative measures on $S$ (i.e., vectors with nonnegative entries), the Hilbert
The properties of Hilbert metric, listed above, provide

\[
H(p, q) = \begin{cases} 
\log \frac{\max_{q_i > 0} \{p_i/q_i\}}{\min_{q_i > 0} \{p_i/q_i\}}, & p \sim q, \\
\infty, & p \not\sim q.
\end{cases}
\] (5.1)

The Hilbert metric is known to satisfy the following properties:
1. \(H(c_1 p, c_2 q) = H(p, q)\) for any positive constants \(c_1\) and \(c_2\).
2. for matrix \(A\) with nonnegative entries \((A_{ij})\),
   \(H(Ap, Aq) \leq \tau(A)H(p, q)\) (see, e.g., [38])
   where \(\tau(A) = \frac{1-\sqrt{\psi(A)}}{1+\sqrt{\psi(A)}}\) is the Birkhoff contraction coefficient with
   \[
   \psi(A) = \min_{i,j,k,T} \frac{A_{ik}A_{jl}}{A_{it}A_{jk}}.
   \]
3. \(\|p - q\| \leq \frac{2}{\log 3} H(p, q)\) (2 Lemma 1).

Returning to the filtering problem, let us first consider the special case when \(\nu = \mu\) and thus the signal \(X^\mu\) is the stationary Markov chain. It is well known that \(\pi_t^\mu = \eta_t^\mu / \langle 1, \eta_t^\mu \rangle\), where \(1\) denotes the vector with unit entries, \(\langle \cdot, \cdot \rangle\) is the usual inner product and \(\eta_t^\mu\) solves the Zakai equation

\[
d\eta_t^\mu = A^\star \eta_t^\mu dt + \sigma^{-2} \text{diag}(h) \eta_t^\mu dY_t^\mu
\]
subject to \(\eta_0^\mu = \mu\). Similarly, \(\pi_t^\beta = \eta_t^\beta / \langle 1, \eta_t^\beta \rangle\), where \(\eta_t^\beta\) is the solution of \(\eta_t^\beta = J_{[0,t]}\mu\) subject to \(\eta_t^\beta = \beta\).

The Zakai equation possesses the unique strong solution which is linear with respect to the initial condition. Hence, \(\eta_t^\mu = J_{[0,t]}\mu\) and \(\eta_t^\beta = J_{[0,t]}\beta\), \(t > 0\), where \(J_{[0,t]}\) is the random Cauchy matrix corresponding to \(\tilde{D}\).

The matrix \(J_{[0,t]}\) can be factored (here \([t]\) is the integer part of \(t\)):

\[
J_{[0,t]} = J_{[[t],t]} \left( \prod_{n=2}^{[t]} J_{[n-1,n]} \right) J_{[0,1]}.
\]

The properties of Hilbert metric, listed above, provide

\[
\|[\pi_t^\mu - \pi_t^\beta]\| \leq \frac{2}{\log 3} H(\pi_t^\mu, \pi_t^\beta) = \frac{2}{\log 3} H(J_{[0,t]}\mu, J_{[0,t]}\beta)
\]

\[
\leq \frac{2}{\log 3} \tau(J_{[[t],t]}) \prod_{n=2}^{[t]} \tau(J_{[n-1,n]}) H(J_{[0,1]}\mu, J_{[0,1]}\beta).
\]

Assume for a moment that \(H(J_{[0,1]}\mu, J_{[0,1]}\beta) < \infty\) a.s. Then

\[
\lim_{t \to \infty} \frac{1}{t} \log \|[\pi_t^\mu - \pi_t^\beta]\| \leq \lim_{t \to \infty} \frac{1}{t} \sum_{n=2}^{[t]} \log \tau(J_{[n-1,n]})
\]

\[
\leq \lim_{t \to \infty} \frac{1}{[t]} \sum_{n=2}^{[t]} \left( -1 \lor \log \tau(J_{[n-1,n]}) \right) = E \left[ -1 \lor \log \tau(J_{[0,1]}) \right] \leq 0.
\] (5.3)
The equality is implied by the law of large numbers, which is valid since \(-1 \leq \{ -1 \vee \log \tau(J_{[n-1,n]}) \} \leq 0 \) and \( \log \tau(J_{[n-1,n]}) \) is generated by
\[
\{ X_s^\mu - X_n^\mu, W_s - W_{n-1} \}, \quad n - 1 \leq s < n,
\]
where the processes \( X_s^\mu \) and \( W \) are independent and \( X_s^\mu \) is an ergodic Markov chain.

Let \( J_{[n-1,n]}^\mu \) be the matrices defined similarly to \( J_{[n-1,n]}^\nu \) with \( Y_s^\mu \) replaced by \( Y_s^\nu \).

Recall that \( \mu \) is the positive measure on \( \mathbb{S} \), so that \( \nu \ll \mu \) and, in turn, \( \overline{Q}^\nu \ll \overline{Q}^\mu \) (here \( \overline{Q}^\nu \) is the distribution of \( Y_s^\nu \)).

Since (5.3) holds \( \overline{Q}^\nu \)-a.s., it also holds \( \overline{Q}^\mu \)-a.s., i.e., with \( J_{[n-1,n]}^\nu \) replaced by \( J_{[n-1,n]}^\nu \) which gives

**Theorem 5.1.** (version of Theorem 1(a) in Atar and Zeitouni, [2]) Assume that all states of \( \Lambda \) communicate, i.e., \( X \) is an ergodic Markov chain. Assume \( J_{[0,1]}^\beta \) and \( J_{[0,1]}^\nu \) have positive entries a.s. Then,
\[
\lim_{t \to \infty} \frac{1}{t} \log \| \pi_t^\nu - \pi_t^\beta \| \leq E \left[ -1 \vee \log \tau(J_{[0,1]}) \right], \quad \text{a.s..}
\]

Now the statement of Theorem 4.1 follows from the lemma below.

**Lemma 5.2.** The right-hand side of (5.4) is strictly negative.

**Proof.** It suffices to show that all entries of \( J_{[0,1]} \) are positive a.s. For fixed \( i, j \), we have
\[
J_{[0,t]}(i,j) = \delta_{ij} + \int_0^t J_{[0,s]}(i,j) [\lambda_{i} \sigma^{-2} h(a_i) dY_s^\mu + \sum_{r \neq i} \lambda_{r} J_{[0,s]}(r,j) ds].
\]

With the help of Itô formula and with
\[
\phi_t(i) = \exp \{ \lambda_{i} t + \sigma^{-2} h(a_i) Y_t^{\mu} - (1/2) \sigma^{-2} h^2(a_i) t \}
\]
we derive
\[
J_{[0,t]}(j,j) = \phi_t(j) \left( 1 + \int_0^t \phi_{s}^{-1}(j) \sum_{r \neq j} \lambda_{r} J_{[0,s]}(r,j) ds \right),
\]
\[
J_{[0,t]}(i,j) = \phi_t(i) \int_0^t \phi_{s}^{-1}(i) \sum_{r \neq i} \lambda_{r} J_{[0,s]}(r,j) ds, \quad i \neq j.
\]

Also notice that the entries of \( J_{[0,t]} \) are unnormalized conditional probabilities and so nonnegative a.s. Since all states of \( \Lambda \) communicate, for pair of indices \( (i,j) \) there is a string of indexes \( j = i_\ell, \ldots, i_1 = i \) such that \( \lambda_{i_{\ell-1}} \ldots \lambda_{i_1} > 0 \). So from (5.5), it follows that a.s.
\[
J_{[0,t]}(i_\ell, i_\ell) \geq \phi_t(i_\ell) > 0,
\]
\[
J_{[0,t]}(i_{\ell-1}, i_\ell) \geq \phi_t(i_{\ell-1}) \int_0^t \phi_{s}^{-1}(i_{\ell-1}) \lambda_{i_{\ell-1}} J_{[0,s]}(i_{\ell-1}, i_\ell) ds > 0,
\]
\[
J_{[0,t]}(i_{\ell-2}, i_\ell) \geq \phi_t(i_{\ell-2}) \int_0^t \phi_{s}^{-1}(i_{\ell-2}) \lambda_{i_{\ell-2}} J_{[0,s]}(i_{\ell-2}, i_\ell) ds > 0
\]
for any \( t > 0 \), and so on until we get \( J_{[0,t]}(i_1, i_\ell) > 0, \ t > 0 \). \( \square \)
5.2. The proof of Theorem 4.2. Denote $\rho_{ji}(t) = P(X_0^\beta = a_j | Y_{0:t}^\beta, X_t^\beta = a_i)$. If $\beta$ is a positive distribution, then by Lemma 9.5 in [29, Chap. 9] we have

$$\rho_{ji}(0) = \begin{cases} 1, & j = i \\ 0, & j \neq i \end{cases}$$

(5.6)

$$\frac{d\rho_{ji}(t)}{dt} = \sum_{r \neq i} \frac{\lambda_{ri}\pi_i^\beta(r)}{\pi_i^\beta(i)} (\rho_{jr}(t) - \rho_{ji}(t)), \quad i = 1, \ldots, n.$$  

Remark 3. By the arguments, used in the proof of Lemma 5.2, it can be readily shown that $\pi_i^\beta(i) > 0$ a.s., $i = 1, \ldots, n$ for any $t > 0$. Then (5.6) remains valid for $t > t_0$ for any $t_0 > 0$ initialized by

$$\rho_{ji}(t_0) = P(X_0^\beta = a_j | Y_{0:t_0}^\beta, X_{t_0}^\beta = a_i).$$

Set $i^c(t) = \text{argmax}_{i \in S} \rho_{ji}(t)$ and $i^c(t) = \text{argmin}_{i \in S} \rho_{ji}(t)$ (if the maximum or the minimum are attained at several indices, the lowest one is taken by convention). Set

$$\rho^c(t) := \rho_{ji^c(t)}(t) \quad \text{and} \quad \rho^c(t) := \rho_{ji^c(t)}(t).$$

Lemma 5.3. The processes $\rho^c(t)$ and $\rho^c(t)$ have absolutely continuous paths with

$$\frac{d\rho^c(t)}{dt} = \sum_{i=1}^n I(i^c(t) = i) \rho_{ji}(t) dt,$$

(5.8)

and

$$\frac{d\rho^c(t)}{dt} = \sum_{i=1}^n I(i^c(t) = i) \rho_{ji}(t) dt.$$  

The proof of this lemma uses two results formulated in Propositions 5.2 and 5.3 below.

Proposition 5.4. (Theorem A.6.3 in Dupuis and Ellis [21].) Let $g = g(t)$ be an absolutely continuous function mapping of $[0, 1]$ into $\mathbb{R}$. Then for each real number $a$ the set $\{ t : g(t) = a, g(t) \neq 0 \}$ has Lebesgue measure 0.

Proposition 5.5. Let $X(t, \omega)$ be a random process with absolutely continuous paths with respect to $dt$ in the sense that there exists a measurable random process $x(t, \omega)$ such that $\int_0^t |x(s, \omega)| ds < \infty$ a.s., $t > 0$, and

$$X(t, \omega) = X(0, \omega) + \int_0^t x(s, \omega) ds.$$  

(5.9)

Then

$$|X(t, \omega)| = |X(0, \omega)| + \int_0^t \text{sign}(X(s, \omega)) x(s, \omega) ds,$$

where $\text{sign}(0) = 0$.

Proof. Set $V_t(\omega) = \int_0^t |x(s, \omega)| ds$ and notice that for any $t' \leq t''$ it holds that

$$|X(t'', \omega)| - |X(t', \omega)| \leq |X(t'', \omega) - X(t', \omega)| \leq (V_{t''}(\omega) - V_{t'}(\omega)).$$
Hence, for fixed $\omega$, the function $|X(t, \omega)|$ possesses bounded total variation for any finite time interval. Denote $U_t(\omega)$ this total variation corresponding to $[0, t]$. Obviously, $dU_t(\omega) \ll dV_t(\omega) \ll dt$. Recall that $U_t(\omega) = U_t^i(\omega) + U_t^m(\omega)$, where $U_t^i(\omega)$, $U_t^m(\omega)$ are increasing continuous in $t$ functions such that for any $t > 0$ and measurable set $A$ from $\mathbb{R}^1$, $\int_{[0, t] \cap A} dU_t^i(\omega) = 0$ and $\int_{[0, t] \cap A^c} dU_t^i(\omega) = 0$, and at the same time, $|X(t, \omega)| = U_t^m(\omega) - U_t^i(\omega)$. Since $dU_t^i \ll dU_t(\omega)$, $dU_t^m \ll dU_t(\omega)$, it follows $d|X(t, \omega)| \ll dU_t(\omega) \ll dV_t(\omega) \ll dt$ and so that

$$(5.10) \quad |X(t, \omega)| = |X(0, \omega)| + \int_0^t g(s, \omega) ds$$

though we may not claim that $g(t, \omega)$ is measurable in $(t, \omega)$.

Now, we show that $\text{sign}(X(s, \omega))x(s, \omega)$ is a measurable version of $g(s, \omega)$. By (5.10), we have $X^2(t, \omega) = X^2(0, \omega) + 2 \int_0^t X(s, \omega)x(s, \omega)ds$. At the same time by (5.10) it holds $|X(t, \omega)|^2 = |X(0, \omega)|^2 + 2 \int_0^t |X(s, \omega)|g(s, \omega)ds$. Hence, the following identity is valid: for any $t \geq 0$

$$\int_0^t |X(s, \omega)|g(s, \omega)ds \equiv \int_0^t X(s, \omega)x(s, \omega)ds.$$ 

Therefore, $|X(s, \omega)|g(s, \omega) = X(s, \omega)x(s, \omega)$ for almost all $s$ with respect to Lebesgue measure. Consequently, we have $I(|X(s, \omega)| \neq 0)g(s, \omega) = \text{sign}(X(s, \omega))x(s, \omega)$ for almost all $s$ with respect to Lebesgue measure. It remains to show that

$$I(X(s, \omega) = 0)g(s, \omega) = 0$$

for almost all $s$ with respect to Lebesgue measure. Taking into account (5.10), it suffices to prove that $\int_0^\infty I(X(s, \omega) = 0)d|X(s, \omega)| = 0$, a.s. On the other hand, whereas $d|X(t, \omega)| \ll dV_t(\omega)$, it suffices to show that $\int_0^\infty I(X(s, \omega) = 0)dV_t(\omega) = 0$, a.s. The latter holds by Proposition 5.3.

Now we give the proof for Lemma 5.2.

Proof. Let us introduce $\rho^{0,1}(t) = \rho_{j1} \vee \rho_{j2} \vee \cdots \vee \rho_{ji}$ and $\rho_{0,i}(t) = \rho_{j1} \wedge \rho_{j2} \wedge \cdots \wedge \rho_{ji}$ and notice that $\rho^{0,n}(t) = \rho^{0}(t)$, $\rho_{0,n}(t) = \rho_{0}(t)$.

The use of obvious identities

$$\rho^{0,2}(t) + \rho_{0,2}(t) = \rho_{j1}(t) + \rho_{j2}(t),$$

$$\rho^{0,2}(t) - \rho_{0,2}(t) = |\rho_{j1}(t) - \rho_{j2}(t)|$$

and the fact, provided by Proposition 5.3, that $d|\rho_{j1}(t) - \rho_{j2}(t)| = p(t, \omega)dt$ with measurable derivative $p(\omega, t)$, allow us to claim that $\rho^{0,2}(t)$ and $\rho_{0,2}(t)$ are absolutely continuous with respect to $dt$ with measurable derivatives.

Further, taking into account $\rho^{0,i}(t) = \rho^{0,i-1}(t) \vee \rho_{ji}$ and $\rho_{0,i}(t) = \rho_{0,i-1}(t) \wedge \rho_{ji}(t)$ and consequent identities

$$\rho^{0,i}(t) + \rho^{0,i-1}(t) \wedge \rho_{ji}(t) = \rho^{0,i-1}(t) + \rho_{j1}(t)$$

$$\rho^{0,i}(t) - \rho^{0,i-1}(t) \wedge \rho_{ji}(t) = |\rho^{0,i-1}(t) - \rho_{j1}(t)|$$

$$\rho_{0,i-1}(t) \vee \rho_{ji}(t) + \rho_{0,i}(t) = \rho_{0,i-1}(t) + \rho_{j1}(t)$$

$$\rho_{0,i-1}(t) \vee \rho_{ji}(t) - \rho_{0,i}(t) = |\rho_{0,i-1}(t) - \rho_{j1}(t)|$$

absolute continuity for $\rho^{0}(t)$ and $\rho_{0}(t)$ is verified by the induction method.
Thus, \( dp^\omega(t) = u(t)dt \) with some density \( u(t) \) such that \( \int_0^t |u(s)|ds < \infty \) a.s., \( t > 0 \). On the other hand, since \( \sum_{i=1}^n I(i^\omega(t) = i) = 1 \), we have

\[
\rho^\omega(t) = \rho^\omega(0) + \int_0^t \sum_{i=1}^n I(i^\omega(s) = i)u(s)ds.
\]

So, it suffices to show that for any \( t > 0 \) and any \( i = 1, 2, \ldots, n \)

\[
\int_0^t I(i^\omega(s) = i)|u(s) - \rho_{ji}(s)|ds = 0, \text{ a.s.}
\]

The latter holds true by Proposition 5.4, since

\[
\sum_{i=1}^n \int_0^t I(i^\omega(s) = i)\rho_{ji}(s)ds = \int_0^t \rho^\omega(s) - \rho_{ji}(s)ds = 0.
\]

\[\blacksquare\]

**Lemma 5.6.** Under the assumptions of Theorem 1.2

\[\lim_{t \to \infty} \frac{1}{t} \log \max_{1 \leq j, k, \ell \leq n} |\rho_{jk}(t) - \rho_{j\ell}(t)| \leq - \sum_{i=1}^n \mu_i \min_{i \neq r} \lambda_r.\]

**Proof.** By 5.6 and 5.8, we have \(^2\)

\[
\frac{dp_{i\omega}}{dt} = \sum_{r \neq i_\omega} \frac{\lambda_{r\omega}(i_\omega)\pi^\beta_r(i_{i\omega})}{\pi^\beta_r(i_\omega)} (p_{jr}(t) - p_{i\omega}(t))
\]

\[\frac{dp^\omega}{dt} = \sum_{r \neq i^\omega} \frac{\lambda_{r\omega}(i^\omega)\pi^\beta_r(i_{i^\omega})}{\pi^\beta_r(i_{i^\omega})} (p_{jr}(t) - p^\omega(t)).\]

In what follows, we will omit the time variable in \( i_\omega(t) \) and \( i^\omega(t) \) for brevity. Set \( \Delta_t = \rho^\omega(t) - \rho_{i\omega}(t) \). By (5.12), we have

\[
\frac{d\Delta_t}{dt} = - \sum_{r \neq i^\omega} \frac{\lambda_{r\omega}(i^\omega)\pi^\beta_r(i_{i^\omega})}{\pi^\beta_r(i_{i^\omega})} (p^\omega(t) - p_{jr}(t)) - \sum_{r \neq i_\omega} \frac{\lambda_{r\omega}(i_\omega)\pi^\beta_r(i_{i_\omega})}{\pi^\beta_r(i_{i_\omega})} (p_{jr}(t) - p_{i\omega}(t))
\]

\[\Delta_t \left( \frac{\lambda_{i\omega}(i_{i_\omega})\pi^\beta_{i_\omega}(i_{i^\omega})}{\pi^\beta_{i_\omega}(i_{i_\omega})} + \frac{\lambda_{i_\omega}(i_{i_\omega})\pi^\beta_{i_\omega}(i_{i^\omega})}{\pi^\beta_{i_\omega}(i_{i_\omega})} \right) + \sum_{r \neq i^\omega} \left[ \frac{\lambda_{r\omega}(i_{i^\omega})\pi^\beta_r(i_{i^\omega})}{\pi^\beta_r(i_{i^\omega})} \left( \frac{p^\omega(t) - p_{jr}(t)}{\Delta_t} \right) \right] - \sum_{r \neq i_\omega} \left[ \frac{\lambda_{r\omega}(i_{i_\omega})\pi^\beta_r(i_{i_\omega})}{\pi^\beta_r(i_{i_\omega})} \left( \frac{p_{jr}(t) - p_{i\omega}(t)}{\Delta_t} \right) \right] \right).\]

\(^2\)In 5.12, ..., 5.14 we use for brevity a form of differential equalities (inequalities) which are valid for any \( \omega \) and almost all \( t \) with respect to Lebesgue measure.
STABILITY OF THE WONHAM FILTER

Letting $0/0 = 1/2$, set $\alpha_r(t) = \frac{\rho_s(t) - \rho_i(t)}{\Delta_t}$. Then, we get $1 - \alpha_r(t) = \frac{\rho_i(t) - \rho_s(t)}{\Delta_t}$ and $0 \leq \alpha_r(t) \leq 1$ and (5.13) implies

$$
\frac{d\Delta_t}{dt} = -\Delta_t \left( \frac{\lambda_{i_0} \pi_t^\beta(i_0)}{\pi_t^\beta(i_0)} + \frac{\lambda_{i_0} \pi_t^\beta(i_0)}{\pi_t^\beta(i_0)} \right)

- \Delta_t \left( \sum_{r \neq i_0} \left[ \alpha_r(t) \frac{\lambda_{r,i_0} \pi_t^\beta(r)}{\pi_t^\beta(i_0)} + (1 - \alpha_r(t)) \frac{\lambda_{r,i_0} \pi_t^\beta(r)}{\pi_t^\beta(i_0)} \right] \right)

\leq -\Delta_t \left( \lambda_{i_0} \pi_t^\beta(i_0) + \lambda_{i_0} \pi_t^\beta(i_0) \right)

- \Delta_t \left( \sum_{r \neq i_0} \left[ \alpha_r(t) \lambda_{r,i_0} + (1 - \alpha_r(t)) \lambda_{r,i_0} \right] \pi_t^\beta(r) \right)

\leq -\Delta_t \left( \lambda_{i_0} \pi_t^\beta(i_0) + \lambda_{i_0} \pi_t^\beta(i_0) + \sum_{r \neq i_0} \left[ \lambda_{r,i_0} \wedge \lambda_{r,i_0} \right] \pi_t^\beta(r) \right).

(5.14)

Recall that all offdiagonal entries of $\Lambda$ are nonnegative and $\sum_{r=1}^n \lambda_{ir} = 0$ for any $i$. Then, $|\lambda_{i_0 i_0}| \wedge |\lambda_{i_0 i_0}| \geq \lambda_{i_0 i_0}$, $|\lambda_{i_0 i_0} \wedge |\lambda_{i_0 i_0} \geq \lambda_{i_0 i_0}$, and (5.14) provides

$$
\frac{d\Delta_t}{dt} \leq -\Delta_t \sum_{r=1}^n \left( \left| \lambda_{r,i_0} \wedge \lambda_{r,i_0} \right| \pi_t^\beta(r) \right) \leq -\Delta_t \sum_{r=1}^n \min_{i \neq r} |\lambda_{ri}| \pi_t^\beta(r).

$$

Since the derivative $\frac{d\Delta_t}{dt}$ is defined for each $\omega$ and almost everywhere (a.e.) in $t$ with respect to $dt$, the above inequality $\frac{d\Delta_t}{dt} \leq -\Delta_t \sum_{r=1}^n \pi_t^\beta(r) \min_{i \neq r} \lambda_{ri}$ is also valid a.e. So, it allows us to define a.e. the function

$$
H(t) = -\Delta_t \sum_{r=1}^n \pi_t^\beta(r) \min_{i \neq r} \lambda_{ri} - \frac{d\Delta_t}{dt}.

$$

Moreover, for the definiteness, we may redefine $H(t)$ everywhere so as $H(t) \geq 0$. Then we have

$$
d\Delta_t = -\left[ \Delta_t \sum_{r=1}^n \pi_t^\beta(r) \min_{i \neq r} \lambda_{ri} + H(t) \right] dt.

$$

Notice also that $\int_t^t |H(s)| ds < \infty$, a.s. for any $t > 0$ and recall that $\Delta_0 = 1$. Then, we get

$$
\Delta_t = \exp \left( -\int_0^t \sum_{r=1}^n \pi_t^\beta(r) \min_{i \neq r} \lambda_{ri} ds \right) - \int_0^t \exp \left( -\int_s^t \sum_{r=1}^n \pi_t^\beta(r) \min_{i \neq r} \lambda_{ri} du \right) H(s) ds

$$

and in turn
\[
\frac{1}{t} \log \Delta_t \leq - \sum_{r=1}^{n} \left( \min_{i \neq r} \lambda_r \right) \frac{1}{t} \int_0^t \pi_t^\beta(r) ds.
\]
So, it is left to verify that
\[
(5.15) \quad \lim_{t \to \infty} \frac{1}{t} \int_0^t \pi_t^\beta(r) ds = \mu_r, \quad \text{a.s.}
\]
Similarly to (1.3), \( \pi_t^\beta \) satisfies
\[
d\pi_t^\beta = \Lambda^* \pi_t^\beta dt + \sigma^{-2} \left( \text{diag}(\pi_t^\beta) - \pi_t^\beta (\pi_t^\beta)^* \right) h(dY_t^\beta - \sigma^* \pi_t^\beta dt).
\]
Recall that \( \sigma^{-1}(Y_t^\beta - \int_0^t h^* \pi_s^\beta ds) \) is the innovation Wiener process (see, e.g., Theorem 9.1 in Chapter 10 in [30]). Hence \( M_t = \int_0^t \left( \text{diag}(\pi_t^\beta) - \pi_t^\beta (\pi_t^\beta)^* \right) h(dY_t^\beta - \sigma^* \pi_t^\beta dt) \) is vector-valued continuous martingale. Its entries \( M_i(i), i = 1, \ldots, n \), have predictable quadratic variation processes \( \langle M(i) \rangle_t \) with the following property:
for some positive constant \( c \), \( d\langle M(i) \rangle_t \leq cd^t \). Then by Theorem 10 in Chapter 3 in [31], \( \lim_{t \to \infty} \frac{1}{t} M_t(i) = 0 \), a.s. This fact and the boundedness of \( \pi_t^\beta \) provide
\[ \Lambda^* \lim_{t \to \infty} \frac{1}{t} \int_0^t \pi_s^\beta ds = 0. \]
The vector \( Z_t = \frac{1}{t} \int_0^t \pi_s^\beta ds \) has nonnegative entries, whose sum equals 1. Therefore the limit vector \( Z_\infty \), obeying the same property, is the unique solution of the linear algebraic equation \( \Lambda^* Z_\infty = 0 \), i.e., \( Z_\infty = \mu \).

To prove Theorem 22 without loss generality, due to Remark 8, we may assume that \( \nu \sim \beta \). Then, we show that for any \( t \geq 0 \) and \( i = 1, \ldots, n \)
\[
(5.16) \quad \left| \pi_t^\nu(i) - \pi_t^\beta(i) \right| \leq n \max_j \left| \frac{d\nu}{d\mu}(a_j) \right| \max_{1 \leq i,j,k \leq d} \left| \rho_{ij}(t) - \rho_{jk}(t) \right|.
\]
Recall that \( Q^\nu \) and \( Q^\beta \) are distributions of \( (X^\nu, Y^\nu) \) and \( (X^\beta, Y^\beta) \) respectively, which are equivalent, by virtue of \( \nu \sim \beta \), with
\[
\frac{dQ^\beta}{dQ^\nu}(X^\nu, Y^\nu) = \frac{d\beta}{d\nu}(X^\nu) \quad \text{and} \quad \frac{dQ^\nu}{dQ^\beta}(X^\beta, Y^\beta) = \frac{d\nu}{d\beta}(X^\beta).
\]
Now, we show that for any \( i = 1, \ldots, d \) and \( t > 0 \), \( Q^\nu \)- and \( Q^\beta \)-a.s.
\[
(5.17) \quad \pi_t^\beta(i) = \sum_{j=1}^{\max_{i,j,k} \left| \rho_{ij}(t) - \rho_{jk}(t) \right|}, \quad \text{a.e.} \quad \frac{d\nu}{d\mu}(a_j) P \left( X^\nu_t = a_j, X^\nu_t = a_i \right| \mathcal{F}_t^\nu) \quad \text{and} \quad \frac{d\beta}{d\nu}(X^\nu_t) \left| \mathcal{F}_t^\nu \right) \quad \text{a.e.}
\]
To this end, with any bounded \( \mathcal{B}_t^\nu \)-measurable function \( \psi_t(y) \), write
\[
E\psi_t(Y^\nu) \pi_t^\beta(i) E \left( \frac{d\beta}{d\nu}(X^\nu_t) \left| \mathcal{F}_t^\nu \right) \right) = E\psi_t(Y^\nu) \pi_t^\beta(i) \frac{d\beta}{d\nu}(X^\nu_t)
\]
\[= E\psi_t(Y^\nu) \pi_t^\beta(i) \frac{dQ^\beta}{dQ^\nu}(X^\nu_t, Y^\nu) = E\psi_t(Y^\beta) \pi_t^\beta(i)
\]
\[= E\psi_t(Y^\beta) I(X^\beta_t = a_i) = E\psi_t(Y^\nu) I(X^\nu_t = a_i) \frac{dQ^\beta}{dQ^\nu}(X^\nu_t, Y^\nu)
\]
\[= E\psi_t(Y^\nu) I(X^\nu_t = a_i) \frac{d\beta}{d\nu}(X^\nu_t) = E\psi_t(Y^\nu) E \left( I(X^\nu_t = a_i) \frac{d\beta}{d\nu}(X^\nu_t) \right| \mathcal{F}_t^\nu).\]
Hence, by the arbitrariness of \( \psi_t(y) \),
\[
\pi_t^{\beta}(i)E\left(\frac{d\beta}{d\nu}(X'_0)|\mathcal{F}_{[0,t]}\right) = E(I(X'_t = a_i)\frac{d\beta}{d\nu}(X'_0)|\mathcal{F}_{[0,t]}).
\]
Further, \( Q' \sim Q^\beta \) provides \( E\left(\frac{d\beta}{d\nu}(X'_0)|\mathcal{F}_{[0,t]}\right) > 0 \), \( Q' \)- and \( Q^\beta \)-a.s., so that
\[
\pi_t^{\beta}(i) = \frac{E(I(X'_t = a_i)\frac{d\beta}{d\nu}(X'_0)|\mathcal{F}_{[0,t]})}{E\left(\frac{d\beta}{d\nu}(X'_0)|\mathcal{F}_{[0,t]}\right)}
\]
and it remains to notice that
\[
E(I(X'_t = a_i)\frac{d\beta}{d\nu}(X'_0)|\mathcal{F}_{[0,t]} = \sum_{j=1}^n \frac{d\beta}{d\nu}(a_j)P(X'_0 = a_j, X'_t = a_j|\mathcal{F}_{[0,t]}).
\]
Taking into consideration (5.17), we find
\[
|\pi'_t(i) - \pi_t^{\beta}(i)| = \left|\pi'_t(i) - \frac{\sum_{j=1}^n \left(\frac{d\beta}{d\nu}(a_j)P(X'_0 = a_j, X'_t = a_j|\mathcal{F}_{[0,t]})\right)}{E\left(\frac{d\beta}{d\nu}(X'_0)|\mathcal{F}_{[0,t]}\right)}\right|
\]
\[
= \sum_{j=1}^n \frac{d\beta}{d\nu}(a_j)\left|\pi'_t(i)P(X'_0 = a_j|\mathcal{F}_{[0,t]}) - P(X'_0 = a_j, X'_t = a_j|\mathcal{F}_{[0,t]})\right|
\]
Then, since by the Jensen inequality \(1/E\left(\frac{d\beta}{d\nu}(X'_0)|\mathcal{F}_{[0,t]}\right) \leq E\left(\frac{d\beta}{d\nu}(X'_0)|\mathcal{F}_{[0,t]}\right)\), we get the chain of estimates
\[
|\pi'_t(i) - \pi_t^{\beta}(i)| \leq \max_{a_j \in \mathcal{E}} \frac{d\beta}{d\nu}(a_j) \max_{a_j \in \mathcal{E}} \frac{d\nu}{d\beta}(a_j)
\]
\[
\times \sum_{j=1}^n \pi'_t(i)\left|P(X'_0 = a_j|\mathcal{F}_{[0,t]}) - P(X'_0 = a_j, X'_t = a_j|\mathcal{F}_{[0,t]})\right|
\]
\[
\leq \max_{a_j \in \mathcal{E}} \frac{d\beta}{d\nu}(a_j) \max_{a_j \in \mathcal{E}} \frac{d\nu}{d\beta}(a_j)
\]
\[
\times \sum_{j=1}^n \left|P(X'_0 = a_j|\mathcal{F}_{[0,t]}) - P(X'_0 = a_j, X'_t = a_j|\mathcal{F}_{[0,t]})\right|
\]
\[
= \max_{a_j \in \mathcal{E}} \frac{d\beta}{d\nu}(a_j) \max_{a_j \in \mathcal{E}} \frac{d\nu}{d\beta}(a_j) \sum_{j=1}^n \left|P(X'_0 = a_j|\mathcal{F}_{[0,t]}) - \rho_{j1}(t)\right|
\]
(5.18)
The obvious formula \( P(X'_0 = a_j|\mathcal{F}_{[0,t]} = \sum_{k=1}^n \pi'_t(k)\rho_{jk}(t)\), and (5.18) provide
\[
|\pi'_t(i) - \pi_t^{\beta}(i)| \leq \max_{a_j \in \mathcal{E}} \frac{d\beta}{d\nu}(a_j) \max_{a_j \in \mathcal{E}} \frac{d\nu}{d\beta}(a_j) \sum_{j=1}^n \sum_{k=1}^n \pi'_t(k)\rho_{jk}(t) - \rho_{ji}(t)\]
(5.19)
and \(5.10\). Thus, by Lemma \(5.6\) the desired statement \(1.11\) holds true.

5.3. The proof of Theorem \(4.3\)

We start with the following lemma.

**Lemma 5.7.** Under the assumptions of Theorem \(4.3\) for any \(t > 0\)

\[
\max_{1 \leq i, k, \ell \leq n} |\rho_{jk}(t) - \rho_{j\ell}(t)| \leq \exp \left( -2t \min_{p \neq q} \sqrt{\lambda_{pq} \lambda_{qp}} \right),
\]

**Proof.** Here we follow the notations from Lemma \(5.6\) From \(5.20\) it follows that

\[
\frac{d\triangle_t}{dt} \leq -\triangle_t \left( \frac{\lambda_{i_0, i_0} \pi^\beta_t (i_0)}{\pi^\beta_t (i_0)} + \frac{\lambda_{i_0, i_0} \pi^\beta_t (i)}{\pi^\beta_t (i_0)} \right)
\]

subject to \(\triangle_0 = 1\). Set \(\tau = \inf \{ t : \pi^\beta_t (i_0) = 0 \}\). Since \(\triangle_t\) is nonincreasing, \(\triangle_t \equiv 0\) for \(t \geq \tau\), and \(5.20\) holds trivially. For \(t < \tau\), as previously we find

\[
\triangle_t \leq \exp \left\{ -\int_0^t \left( \frac{\lambda_{i_0, i_0} \pi^\beta_t (i_0)}{\pi^\beta_t (i_0)} + \frac{\lambda_{i_0, i_0} \pi^\beta_t (i)}{\pi^\beta_t (i_0)} \right) ds \right\}
\]

\[
\leq \exp \left\{ -\int_0^t \min_{x \geq 0} \left( \lambda_{i_0, i_0} x + \lambda_{i_0, i_0} \frac{1}{x} \right) ds \right\}
\]

\[
= \exp \left\{ -\int_0^t 2 \lambda_{i_0, i_0} \lambda_{i_0, i_0} ds \right\} \leq \exp \left( -2t \min_{p \neq q} \sqrt{\lambda_{pq} \lambda_{qp}} \right),
\]

and \(5.20\) follows. \(\square\)

To prove the first statement of the theorem, taking into account \(\nu \ll \beta\) we replicate a fragment from the proof of Proposition \(2.1\).

Using the notations introduced in section \(2.1\) write \(\pi^\nu_t (i) : = \pi^\nu_t (f)\) and \(\pi^\beta \nu_t (i) : = \pi^\beta \nu_t (f)\) for \(f(x) = I(x = a_i)\). Then,

\[
E|\pi^\beta \nu_t (i) - \pi^\nu_t (i)| \leq E \left( E \left( \frac{d\nu}{d\beta} (X^\beta_0 | \mathcal{Y}^\beta_{[0,t]} \right) - E \left( \frac{d\nu}{d\beta} (X^\beta_0 | \mathcal{Y}^\beta_{(0,\infty)} \cup \mathcal{Y}^{t \beta}_{[t,\infty]} \right) \right)
\]

and, since \((X^\beta, Y^\beta)\) is a Markov process,

\[
E \left( \frac{d\nu}{d\beta} (X^\beta_0 | \mathcal{Y}^\beta_{[0,\infty)} \cup \mathcal{Y}^{t \beta}_{[t,\infty]} \right) = E \left( \frac{d\nu}{d\beta} (X^\beta_0 | \mathcal{Y}^\beta_{[0,t]} \cup \mathcal{Y}^{t \beta}_{[t,\infty]} \right).
\]

Then,

\[
E \left( \frac{d\nu}{d\beta} (X^\beta_0 | \mathcal{Y}^\beta_{[0,t]} \right) - E \left( \frac{d\nu}{d\beta} (X^\beta_0 | \mathcal{Y}^\beta_{[0,\infty)} \cup \mathcal{Y}^{t \beta}_{[t,\infty]} \right)
\]

\[
= \sum_{j=1}^n \left( P(X^\beta_0 = a_j | \mathcal{Y}^\beta_{[0,t]} \right) - P(X^\beta_0 = a_j | \mathcal{Y}^\beta_{[0,\infty)} \cup \mathcal{Y}^{t \beta}_{[t,\infty]} \right)
\]

\[
= \sum_{j=1}^n \sum_{t=1} I(X^\beta_t = a_j) \frac{d\nu}{d\beta} (a_j) \left( P(X^\beta_0 = a_j | \mathcal{Y}^\beta_{[0,t]} \right) - \rho_{j\ell}(t) \right)
\]

\[
= \sum_{j=1}^n \sum_{t=1} \sum_{k=1}^n \pi^\beta_t (k) I(X^\beta_t = a_j) \frac{d\nu}{d\beta} (a_j) \left( \rho_{jk}(t) - \rho_{j\ell}(t) \right)
\]

\[
\leq \max_{1 \leq j, k, \ell \leq n} |\rho_{jk}(t) - \rho_{j\ell}(t)| \sum_{j=1}^n \frac{d\nu}{d\beta} (a_j).
\]
The first statement of Theorem 4.3 follows from (5.22), (5.23), and Lemma 5.7. The second statement follows from (5.10) and Lemma 5.7.

6. Proofs for non-ergodic case. Recall that in the non-ergodic setting under consideration

$$S = \left\{ a_1, \ldots, a_n, \ldots, a_1, \ldots, a_m \right\}, \quad m \geq 2$$

with subalphabets $S_1, \ldots, S_m$ noncommunicating in the sense of (1.2).

6.1. Auxiliary lemmas. In this subsection, $X_t^j$ is an independent copy of $X_t^j$ with the initial distribution $\mu_j$, defined on some auxiliary probability space $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P})$ and $E$ is the expectation with respect to $\tilde{P}$. Recall that $\mu_j$ is the invariant measure, so that $X_t^j$ is stationary process.

**Lemma 6.1.** Fix $r > 0$ and define $Z_n = \sum_{i=1}^{n} (Y_{ir}^\beta - Y_{(i-1)r}^\beta)^2$. Then with $n \to \infty$

$$\frac{1}{n} Z_n \to r + \sum_{j=1}^{m} I(X_0^\beta \in S_j) \tilde{E} \left( \int_0^r h(\tilde{X}_s^j) \, ds \right)^2.$$

**Proof.** Define

$$F(i) = E \left[ \left( \int_0^r h(X_s^\beta) \, ds \right)^2 \right| X_0^\beta = a_i]$$

and $\mathcal{G}_n = \sigma\{Y_{(i,n)r}\} \vee \sigma\{X_{(i,n)r}\}$. Then $E \left[ \left( Y_{(i+1)n}^\beta - Y_{in}^\beta \right)^2 \right| \mathcal{G}_n] = r + F(X_{nr}^\beta)$ so that the sequence $M_n = Z_n - nr - \sum_{i=1}^{n-1} F(X_{ir}^\beta)$ is a martingale with respect to the filtration $(\mathcal{G}_n)_{n \geq 1}$. It is easy to verify that there exists $K < \infty$ such that for all $n$ we have $E(M_{n+1} - M_n)^2 \leq K$. It follows that $(1/n)M_n \to 0$ almost surely as $n \to \infty$ (see, e.g., Chapter VII, Section 5, Theorem 4 in [12]).

Now consider $(1/n) \sum_{i=1}^{n} F(X_{ir}^\beta)$. If $X_0 \in S_j$, then $X_t \in S_j$ for all $t \geq 0$ and the process is ergodic in $S_j$ with stationary distribution $\mu_j$. Applying the ergodic theorem for each class $S_j$ we obtain

$$\frac{1}{n} \sum_{i=0}^{n-1} F(X_{ir}^\beta) \to \sum_{j=1}^{m} \tilde{E}(F(X_0^\beta)) I(X_0^\beta \in S_j) = \sum_{j=1}^{m} \tilde{E} \left( \int_0^r h(\tilde{X}_s^j) \, ds \right)^2 I(X_0^\beta \in S_j)$$

as $n \to \infty$ a.s. Finally

$$\lim_{n \to \infty} \frac{1}{n} Z_n = \lim_{n \to \infty} \frac{1}{n} M_n + r + \lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} F(X_{ir}^\beta)$$

$$= r + \sum_{j=1}^{m} \tilde{E} \left( \int_0^r h(\tilde{X}_s^j) \, ds \right)^2 I(X_0^\beta \in S_j)$$

and we are done. □

With $\tilde{X}_t^j$ defined as in Lemma 6.1 and $r \geq 0$ let $d_j(r) = \tilde{E} \left( \int_0^r h(\tilde{X}_s^j) \, ds \right)^2$.

**Lemma 6.2.** For any $k \neq j$ the following are equivalent:
i. \( d_k(r) = d_j(r) \) for all \( r \geq 0 \):

ii. \( h_j^* \text{diag}(\mu_k) \Lambda^q_k h_k = h_j^* \text{diag}(\mu_j) \Lambda^q_j h_j \) for all \( 0 \leq q \leq n_i + n_j - 1 \).

Proof. Notice first that

\[
    d_j(r) = 2 \bar{E} \int_0^r \int_0^s h(\tilde{X}^*_t) h(\tilde{X}^*_s) \, ds \, dv = 2 \int_0^r \int_0^s \bar{E} h(\tilde{X}^*_t) h(\tilde{X}^*_s) \, ds \, dv
\]

Now, introduce the vector \( \tilde{I_i} \) with entries \( I(\tilde{X}^*_t) = a_i^t \), \( I(\tilde{X}^*_t) = a_i^t \) and notice also that

\[
    \bar{E} h(\tilde{X}^*_t) h(\tilde{X}^*_s) = \bar{E} h_j^* \tilde{I}_i (\tilde{I}_j)^* h_j = \bar{E} h_j^* \tilde{I}_i (\tilde{I}_j)^* e^{\Lambda^q_j} h_j
\]

Therefore \( d_j(r) = 2 \int_0^r \int_0^s h_j^* \text{diag}(\mu^q) e^{\Lambda^q_j} h_j \, dv \, ds \) so, \( d_j(0) = d_j'(0) = 0 \) and

\[
    d_j''(r) = 2 h_j^* \text{diag}(\mu^q) e^{\Lambda^q_j} h_j.
\]

Differentiating with respect to \( r \) a further \( q \) times and then putting \( r = 0 \) we get

\[
    d_j^{(2+q)}(0) = 2 h_j^* \text{diag}(\mu^q) \Lambda^q_j h_j.
\]

It follows immediately that if \( d_k(r) = d_j(r) \) for all \( r \geq 0 \), then

\[
    h_j^* \text{diag}(\mu^q) \Lambda^q_k h_k = h_j^* \text{diag}(\mu^q) \Lambda^q_j h_j
\]

for all \( q \geq 0 \) and so in particular for all \( 0 \leq q \leq n_k + n_j - 1 \).

Suppose conversely that \( h_j^* \text{diag}(\mu^q) \Lambda^q_k h_k = h_j^* \text{diag}(\mu^q) \Lambda^q_j h_j \) for all \( 0 \leq q \leq n_k + n_j - 1 \). The Cayley-Hamilton theorem applied to the \((n_k + n_j) \times (n_k + n_j)\) block diagonal matrix \( \begin{pmatrix} \Lambda_k & 0 \\ 0 & \Lambda_j \end{pmatrix} \) gives constants \( c_0, c_1, \ldots, c_{n_k + n_j - 1} \) so that

\[
    \Lambda^{n_k+n_j}_k = \sum_{q=0}^{n_k+n_j-1} c_q \Lambda^q_k \quad \text{and} \quad \Lambda^{n_k+n_j}_j = \sum_{q=0}^{n_k+n_j-1} c_q \Lambda^q_j.
\]

Therefore we have \( h_j^* \text{diag}(\mu^q) \Lambda^q_k h_k = h_j^* \text{diag}(\mu^q) \Lambda^q_j h_j \) for all \( q > n_j + n_k - 1 \) as well.

Using the fact that \( e^{\Lambda^q_j} = \sum_{q=0}^{\infty} \frac{\Lambda^q_j}{q!} \), we see that \( d_k''(r) = d_j''(r) \) for all \( r \geq 0 \), and hence \( d_k(r) = d_j(r) \) for all \( r \geq 0 \).

Lemma 6.3. Assume (A-2). For any \( \beta \)

\[
    \lim_{t \to \infty} E \left| P(\mathbb{X}_0^\beta \in S_j | \mathscr{G}_{[0,t]}^\beta) - I(\mathbb{X}_0^\beta \in S_j) \right| = 0, \quad j \geq 1.
\]

Proof. We use the notation \( Z_n^{(r)} \) to express the dependence on \( r \) of the function \( Z_n \) in Lemma 6.1. We have \( \frac{1}{n} Z_n^{(r)} \to \sum_{j=1}^{m} h_j^* \mu J(I(\mathbb{X}_0^\beta \in S_j)) \) and

\[
    \frac{1}{n} Z_n^{(r)} \to r + \sum_{j=1}^{m} d_j(r) I(\mathbb{X}_0^\beta \in S_j)
\]

as \( n \to \infty \), a.s. Using the assumption (A-2) and Lemma 6.2 we can find an integer \( \ell \) and numbers \( r_i > 0, i = 1, \ldots, \ell \) and construct a random variable of the form

\[
    V_n = (Y_n^1, Y_n^2, \ldots, Y_n^n) - nr_1, \ldots, Z_n^{(r_\ell)} - nr_\ell
\]

so that \( \frac{1}{n} V_n \to \sum_{j=1}^{m} v_j I(\mathbb{X}_0^\beta \in S_j) \) as \( n \to \infty \), \( P \)-a.s., where the \( v_1, \ldots, v_m \) are distinct vectors in \( \mathbb{R}^{\ell+1} \). Therefore \( \{\mathbb{X}_0^\beta \in S_j\} \) is \( Y_{[0,\infty)} \)-measurable a.s. and the result follows immediately.
6.2. The proof of Theorem 4.4. By Proposition 3.2, it suffices to show that
\[
\lim_{t \to \infty} E \| \pi_t^\beta - \pi_t^{\beta_0} \| = 0.
\]
We introduce a new filter, intermediate between \( \pi_t^\beta \) and \( \pi_t^{\beta_0} \). Define the random variable \( U \) by \( U = j \) on the set \( \{ X_0^\beta \in S_j \} \), and then define
\[
\pi_t^{\beta,U}(i) = P(X_t^\beta = a_i | \mathcal{F}_0^\beta, U).
\]
Then
\[
\| \pi_t^\beta - \pi_t^{\beta,U} \| = \sum_{i=1}^n \left| P(X_t^\beta = a_i | \mathcal{F}_0^\beta) - P(X_t^\beta = a_i | \mathcal{F}_0^\beta, U) \right|
\]
\[
= \sum_{i=1}^n \left| \sum_{j=1}^m P(X_t^\beta = a_i | \mathcal{F}_0^\beta, U = j) \left( P(U = j | \mathcal{F}_0^\beta) - I(U = j) \right) \right|
\]
\[
\leq \sum_{j=1}^m \left| P(U = j | \mathcal{F}_0^\beta) - I(U = j) \right|
\]
and
\[
\| \pi_t^{\beta,U} - \pi_t^{\beta_0} \| = \sum_{i=1}^n \left| P(X_t^\beta = a_i | \mathcal{F}_0^\beta, U) - P(X_t^\beta = a_i | \mathcal{F}_0^\beta, X_0^\beta) \right|
\]
\[
= \sum_{i=1}^n \sum_{j=1}^m I(U = j) \left| P(X_t^\beta = a_i | \mathcal{F}_0^\beta, U = j) - P(X_t^\beta = a_i | \mathcal{F}_0^\beta, U = j, X_0^\beta) \right|
\]
\[
= \sum_{j=1}^m I(U = j) \| \pi_t^{\beta,j} - \pi_t^{\beta_0,j} \|,
\]
where \( \beta^j \) denotes the conditional distribution of \( \beta \) restricted to the subalphabet \( S_j \).

By Lemma 6.3,
\[
\sum_{j=1}^m \left| P(U = j | \mathcal{F}_0^\beta) - I(U = j) \right| \xrightarrow{t \to \infty} 0
\]
while \( \sum_{j=1}^m I(U = j) \| \pi_t^{\beta,j} - \pi_t^{\beta_0,j} \| \xrightarrow{t \to \infty} 0 \) by applying Theorem 4.1 to each \( S_j \).

Appendix A. Proof of Proposition 3.2.

Proof. (Sketch) We use the following construction for \( X \). Let \( X_0 \) be a random variable with values in \( S = \{1, 2, 3, 4\} \) and \( P(X_0 = j) = \nu_j, j = 1, \ldots, 4 \). Introduce independent of \( X_0 \) matrix-valued process
\[
N_t = \begin{pmatrix}
-N_{12}(t) & N_{12}(t) & 0 & 0 \\
0 & -N_{23}(t) & N_{23}(t) & 0 \\
0 & 0 & -N_{34}(t) & N_{34}(t) \\
N_{41}(t) & 0 & 0 & -N_{41}(t)
\end{pmatrix},
\]
where \( N_{ij}(t) \) are independent copies of Poisson process with the unit rate. Let us consider the Itô equation
\[
I_t = I_0 + \int_0^t dN_s \cdot I_s
\]
with \( I_0 \) the vector with entries \( I_0(j) = I(X_0 = j), j = 1, \ldots, 4 \). Since the jumps of Poisson processes \( N_i(t) \)'s are disjoint, for any \( t > 0 \) the vector \( I_t \) has only one nonzero entry. Moreover, whereas the increments of \( N_i \) are independent for nonoverlapping intervals, \( I_t \) is Markov process. It is readily checked that, with the row vector \( g = (1 \ 2 \ 3 \ 4) \), \( X_t = gI_t \) is Markov process with values in \( S \) and the transition intensities matrix \( \Lambda \) and \( I_t(j) = I(X_t = j), j = 1, \ldots, 4 \).

We will follow Theorem 4.10.1 from [31]. The random process \( Y \) has piecewise constant paths with jumps of two magnitudes, +1 and −1. Due to (A.2), its saltus measure \( p(dt, dy) \) is completely described by

\[
\begin{align*}
    p(dt, \{1\}) &= \{ I_{-}(4) dN_{41}(t) + I_{-}(2) dN_{23}(t) \} \\
    p(dt, \{-1\}) &= \{ I_{-}(1) dN_{12}(t) + I_{-}(3) dN_{34}(t) \}.
\end{align*}
\]

So, the compensator \( \overline{\pi}(dt, dy) \) of \( p(dt, dy) \) with respect to the filtration \( (\mathcal{F}_{[0,t]} \}_{t \geq 0} \) is defined as

\[
\begin{align*}
    \overline{\pi}(dt, \{1\}) &= (\pi_{-}(4) + \pi_{-}(2)) dt = (1 - Y_{-}) dt \\
    \overline{\pi}(dt, \{-1\}) &= (\pi_{-}(1) + \pi_{-}(3)) dt = Y_{-} dt.
\end{align*}
\]

Notice also that

\[
\begin{align*}
    p(dt, \{1\}) &= (1 - Y_{-}) dY_t \quad \text{and} \quad p(dt, \{-1\}) = -Y_{-} dY_t.
\end{align*}
\]

Equation (A.2) also gives “drift+martingale” presentation for \( I_1(t), I_2(t) \):

\[
\begin{align*}
    dI_1(t) &= (-I_1(1) + I_1(4)) dt + dM_1(t) \\
    dI_2(t) &= (I_1(1) - I_1(2)) dt + dM_2(t)
\end{align*}
\]

with martingales

\[
\begin{align*}
    M_1(t) &= \int_0^t \left( -I_{-}(1) d(N_{12}(s) - s) + I_{-}(4) d(N_{41}(s) - s) \right) dt \\
    M_2(t) &= \int_0^t \left( I_{-}(1) d(N_{12}(s) - s) - I_{-}(2) d(N_{23}(s) - s) \right) dt.
\end{align*}
\]

Then, by Theorem 4.10.1 in [31], adapted to the case considered, we have

\[
\begin{align*}
    d\pi_1(t) &= (-\pi_1(1) + \pi_1(4)) dt + \int H_1(\omega, t, y) [p(dt, dy) - \overline{\pi}(dt, dy)] d\\omega \\
    d\pi_2(t) &= (\pi_1(1) - \pi_1(2)) dt + \int H_2(\omega, t, y) [p(dt, dy) - \overline{\pi}(dt, dy)] d\\omega,
\end{align*}
\]

where \( H_i(\omega, t, y), i = 1, 2 \), are \( \mathcal{P}(Y) \otimes \mathcal{B}(\mathbb{R}) \)-measurable functions (here \( \mathcal{B}(\mathbb{R}) \) is the Borel \( \sigma \)-algebra on \( \mathbb{R} \) and \( \mathcal{P}(Y) \) is the predictable \( \sigma \)-algebra on \( \Omega \times \mathbb{R}_+ \) with respect to the filtration \( (\mathcal{F}_{[0,t]} \}_{t \geq 0} \). Moreover

\[
H_i(\omega, t, y) = M(\Delta M_i + I_-(i) | \mathcal{P}(Y) \otimes \mathcal{B}(\mathbb{R}))(\omega, t, y) - \pi_{-}(i),
\]

where \( \Delta M_i \) and \( I_-(i) \) are the processes \( M_i(t) - M_i(t-) \) and \( I_-(i) \), respectively, and \( M(\cdot | \mathcal{P}(Y) \otimes \mathcal{B}(\mathbb{R})) \) is the conditional expectation with respect to the measure \( M(d\omega, dt, dy) = P(d\omega)p(dt, dy) \) given \( \mathcal{P}(Y) \otimes \mathcal{B}(\mathbb{R}) \).
By (A.3), \( \Delta M_t(t) + I_{t-}(i) = I_t(i) \) and the structure of compensator \( \mathcal{P} \) provides (here \( \Delta I_t(i) = I_t(i) - I_{t-}(i) \))

\[
M(I(i)|\mathcal{P}(Y) \otimes \mathcal{B}(\mathbb{R})) - \pi_{t-}(i) = M(\triangle I(i)|\mathcal{P}(Y) \otimes \mathcal{B}(\mathbb{R})).
\]

The desired conditional expectation is determined uniquely from the following identity: for any bounded, compactly supported in \( t \) and \( \mathcal{P}(Y) \otimes \mathcal{B}(\mathbb{R}) \)-measurable function \( \phi(\omega, t, y) \)

\[
E \int_0^\infty \int \phi(\omega, t, y) \Delta I_t(i) p(dt, dy)
= E \int_0^\infty \int \phi(\omega, t, y) M(\triangle I(i)|\mathcal{P}(Y) \otimes \mathcal{B}(\mathbb{R}))(\omega, t, y) \mathcal{P}(dt, dy).
\]

By (A.2)

\[
\begin{align*}
\Delta I_t(1) &= -I_{t-}(1) \Delta N_{12}(t) + I_{t-}(4) \Delta N_{41}(t), \\
\Delta I_t(2) &= I_{t-}(1) \Delta N_{12}(t) - I_{t-}(2) \Delta N_{23}(t),
\end{align*}
\]

and so

\[
\begin{align*}
\Delta I_t(1)p(dt, \{1\}) &= I_{t-}(4) dN_{41}(t), \\
\Delta I_t(1)p(dt, \{-1\}) &= -I_{t-}(1) dN_{12}(t), \\
\Delta I_t(2)p(dt, \{1\}) &= -I_{t-}(2) dN_{23}(t), \\
\Delta I_t(2)p(dt, \{-1\}) &= I_{t-}(1) dN_{12}(t).
\end{align*}
\]

Owing to the obvious relations

\[
I_4(t) \equiv I_4(t)(1 - Y_t), \quad I_2(t) \equiv I_2(t)(1 - Y_t), \\
I_1(t) \equiv I_1(t)Y_t, \quad I_3(t) \equiv I_3(t)Y_t
\]

we have

\[
\begin{align*}
\pi_{t-}(2)dt &= \pi_{t-}(2)(1 - Y_{t-})dt, \quad \pi_{t-}(2)dt = \pi_{t-}(2)(1 - Y_{t-})dt \\
\pi_{t-}(1)dt &= \pi_{t-}(1)Y_{t-}dt, \quad \pi_{t-}(3)dt = \pi_{t-}(3)Y_{t-}dt.
\end{align*}
\]

Taking into account (A.3), we find

\[
H_1(\omega, t, y) = \begin{cases} 
\pi_{t-}(4), & y = 1, \\
-\pi_{t-}(1), & y = -1
\end{cases}
\]

\[
H_2(\omega, t, y) = \begin{cases} 
-\pi_{t-}(2), & y = 1, \\
\pi_{t-}(1), & y = -1
\end{cases}
\]

In accordance with (A.3), (A.4), the formulae for \( H_1, H_2 \), and (A.7), we transform (A.6) to

\[
\begin{align*}
d\pi_1(t) &= (-\pi_{t-}(1) + \pi_{t}(4))dt + \pi_{t-}(4)(1 - Y_{t-})(dY_t - dt) + \pi_{t-}(1)Y_{t-}(dY_t + dt) \\
&= \pi_{t-}(4)(1 - Y_{t-})dY_t + \pi_{t-}(1)Y_{t-}dY_t \\
&= (1 - \pi_{t-}(2))(1 - Y_{t-})dY_t + \pi_{t-}(1)Y_{t-}dY_t, \\
d\pi_2(t) &= (\pi_{t}(1) - \pi_{t}(4))dt + \pi_{t-}(2)(1 - Y_{t-})(dY_t - dt) - \pi_{t-}(1)Y_{t-}(dY_t + dt) \\
&= -\pi_{t-}(2)(1 - Y_{t-})dY_t - \pi_{t-}(1)Y_{t-}dY_t.
\end{align*}
\]
Acknowledgements. The authors gratefully acknowledge Boris Tsirelson for bringing [43] and the example in [44] to their attention, Rami Atar for suggesting use of Theorem 1 in [2] for the proof of Theorem 4.1, and the anonymous referees whose comments and advises allowed us to improve the paper significantly.
