Filtrations at the threshold of standardness

Gaël Ceillier, Christophe Leuridan

August 1, 2012

Abstract

A. Vershik discovered that filtrations indexed by the non-positive integers may have a paradoxical asymptotic behaviour near the time \(-\infty\), called non-standardness. For example, two dyadic filtrations with trivial tail \(\sigma\)-field are not necessarily isomorphic. Yet, any essentially separable filtration indexed by the non-positive integers becomes standard when sufficiently many integers are skipped.

In this paper, we focus on the non standard filtrations which become standard if (and only if) infinitely many integers are skipped. We call them filtrations at the threshold of standardness, since they are as close to standardness as they can be although they are non-standard.

Two class of filtrations are studied, first the filtrations of the split-words processes, second some filtrations inspired by an unpublished example of B. Tsirelson. They provide examples which disproves some naive intuitions. For example, it is possible to have a standard filtration extracted from a non-standard one with no intermediate (for extraction) filtration at the threshold of standardness. It is also possible to have a filtration which provides a standard filtration on the even times but a non-standard filtration on the odd times.

keywords: filtrations, standardness, split-words processes.

Introduction

The notion of standardness has been introduced by A. Vershik [10] in the context of decreasing sequences of measurable partitions indexed by the non-negative integers. Vershik’s definition and characterizations of standardness have been translated their original ergodic theoretic formulation into a probabilistic language by M. Émery and W. Schachermayer [2]. In this framework, the objects of focus are the filtrations indexed by non-positive integers. These are the non-decreasing sequences \((\mathcal{F}_n)_{n \leq 0}\) of sub-\(\sigma\)-fields of a probability space \((\Omega, \mathcal{A}, P)\).

All the sub-\(\sigma\)-fields of \(\mathcal{A}\) that we will consider are assumed to be complete and essentially separable with respect to \(P\). By definition, a sub-\(\sigma\)-field of \((\Omega, \mathcal{A}, P)\) is separable if it can be generated as a complete \(\sigma\)-field by a sequence of events, or equivalently, by some real random variable. One can check that a sub-\(\sigma\)-field \(\mathcal{B} \subseteq \mathcal{A}\) is separable if and only if the Hilbert space \(L^2(\Omega, \mathcal{B}, P)\) is separable.

Almost all filtrations that we will consider in this study have the following property: for each \(n\), \(\mathcal{F}_n\) is generated by \(\mathcal{F}_{n-1}\) and by some random variable \(U_n\) which is independent of \(\mathcal{F}_{n-1}\) and uniformly distributed on some finite set with \(r_n\) elements, for some sequence \((r_n)_{n \leq 0}\) of positive integers. Such filtrations are called \((r_n)_{n \leq 0}\)-adic.
For such filtrations, as shown by Vershik [10], standardness turns out to be tantamount to a simpler, much more intuitive property: an \((r_n)\)-adic filtration \(\mathcal{F}\) is standard if and only if \(\mathcal{F}\) is of product type, that is, \(\mathcal{F}\) is the natural filtration of some process \(V = (V_n)_{n \leq 0}\) where the \(V_n\) are independent random variables; in this case, it is easy to see that the process \(V\) can be chosen with the same law as \(U = (U_n)_{n \leq 0}\). So, at first reading, ‘standard’ can be replaced with ‘of product type’ in this introduction.

Although intuitive, the notion of product-type filtrations is not as simple as one could believe. For example, the assumption that the tail \(\sigma\)-field \(F_{-\infty} = \bigcap_{n \leq 0} F_n\) is trivial, and the property \(F_n = F_{n-1} \vee \sigma(U_n)\) for every \(n \leq 0\) do not ensure that \((F_n)_{n \leq 0}\) is generated by \((U_n)_{n \leq 0}\). In the standard case, \((F_n)_{n \leq 0}\) can be generated by some other sequence \((V_n)_{n \leq 0}\) of independent random variables which has the same law as \((U_n)_{n \leq 0}\). In the non-standard case, no sequence of independent random variables can generate the filtration \((F_n)_{n \leq 0}\).

The first examples of such a situation were given by Vershik [10]. By modifying and generalizing one of these examples, M. Smorodinsky [8] and Émery and Schachermayer [2] introduced the split-words processes.

The law of a split-words process depends on an alphabet \(A\), endowed with some probability measure, and a decreasing sequence \((\ell_n)_{n \leq 0}\) of positive integers (the lengths of the words) such that \(\ell_0 = 1\) and the ratios \(r_n = \ell_{n-1}/\ell_n\) are integers. For the sake of simplicity, we consider here only finite alphabets endowed with the uniform measure.

A split-words process is an inhomogeneous Markov process \(((X_n, U_n))_{n \leq 0}\) such that for every \(n \leq 0\):

- \((X_n, U_n)\) is uniform on \(A^{\ell_n} \times [1, r_n]\).
- \(U_n\) is independent of \(\mathcal{F}_{n-1}^{(X,U)}\).
- if one splits the word \(X_{n-1}\) (of length \(\ell_{n-1} = r_n \ell_n\)) into \(r_n\) subwords of lengths \(\ell_n\), then \(X_n\) is the \(U_n\)-th subword of \(X_{n-1}\).

Such a process is well-defined since the sequence of uniform laws on the sets \(A^{\ell_n} \times [1, r_n]\) is an entrance law for the transition probabilities given above. By construction, the natural filtration \(\mathcal{F}^{X,U}_{-\infty}\) of \(((X_n, U_n))_{n \leq 0}\) is \((r_n)_{n \leq 0}\)-adic. One can check that the tail \(\sigma\)-field \(\mathcal{F}^{X,U}_{-\infty}\) is trivial. Thus, it is natural to ask whether \(\mathcal{F}^{X,U}_{-\infty}\) is standard or not.

Whether a split-words process with lengths \((\ell_n)_{n \leq 0}\) generates a standard filtration or not is completely characterised: the filtration is non-standard if and only if

\[
\sum_n \frac{\ln(r_n)}{\ell_n} < +\infty \quad (\Delta).
\]

Note that this condition does not depend on the alphabet \(A\).

In this statement, the ‘if’ part and a partial converse have been proved by Vershik [10] (in a very similar framework) and by S. Laurent [5]. The ‘only if’ part has been proved by D. Heicklen [4] (in Vershik’s framework) and by G. Ceillier [1]. The generalization to arbitrary alphabets has been performed by Laurent in [7]: the characterisations and all the results below still hold are when the alphabet is a Polish space endowed with some probability measure.

Although these examples are rather simple to construct, proving the non-standardness requires sharp tools like Vershik’s standardness criterion [10, 2]. One can also use the
I-cosiness criterion of Émery and Schachermayer [2] which may be seen as more intuitive by probabilists. Actually, Laurent proved directly that both criteria are actually equivalent. Moreover, applying these criteria to the examples above leads to rather technical estimations.

Another question concerns what happens to a filtration when time is accelerated by extracting a subsequence. Clearly, every subsequence of a standard filtration is still standard. But Vershik’s lacunary isomorphism theorem [10] states that from any filtration \((\mathcal{F}_n)_{n \leq 0}\) such that \(\mathcal{F}_0\) is essentially separable and \(\mathcal{F}_{-\infty}\) is trivial, one can extract a filtration \((\mathcal{F}_{\phi(n)})_{n \leq 0}\) which is standard. This striking fact is mind-boggling for anyone who is interested by the boundary between standardness and non-standardness. A natural question arises:

when \((\mathcal{F}_n)_{n \leq 0}\) is not standard, how close to identity the increasing map \(\phi\) (from \(\mathbb{Z}_-\) to \(\mathbb{Z}_-\)) provided by the lacunary isomorphism theorem can be?

Of course, as standardness is an asymptotic property, the extracting map \(\phi\) has to skip an infinity of times integers (equivalently, \(\phi(n) - n \to -\infty\) as \(n \to -\infty\)).

In [10], Vershik provides an example of a non-standard dyadic filtration \((\mathcal{F}_n)_{n \leq 0}\) such that \((\mathcal{F}_{2n})_{n \leq 0}\) is standard. Gorbulsky also provides such an example in [3].

Using the fact that the family of split-words filtrations is stable by extracting subsequences, Ceillier exhibits in [1] an example of a non-standard filtration \((\mathcal{F}_n)_{n \leq 0}\) which is as close to standardness as it can be: every subsequence \((\mathcal{F}_{\phi(n)})_{n \leq 0}\) is standard as soon as \(\phi\) skips an infinity of integers.

This paper is devoted to the filtrations sharing this property. We call them filtrations at the threshold of standardness.

Main results and organization of the paper

Some definitions and classical facts used in the paper are recalled in an annex, at the end of the paper. In the sections 1 and 2 which are the core of the paper, two class of filtrations are studied, first the filtrations of the split-words processes, second some filtrations inspired by an unpublished example of B. Tsirelson.

The case of split-words filtrations

The first part deals with split-words filtrations.

First, we characterise the filtrations at the threshold of standardness among the split-words filtrations.

**Proposition 1.** A split-words filtration with lengths \((\ell_n)_{n \leq 0}\) is at the threshold of standardness if and only if

\[
\sum_{n \leq 0} \frac{\ln(r_n)}{\ell_n} < +\infty \quad (\Delta)
\]

and

\[
\inf_{n \leq 0} \frac{\ln(r_n r_{n-1})}{\ell_n} > 0 \quad (\ast).
\]

Next, we characterise (among the split-words filtrations) the filtrations that cannot be extracted from any split-words filtration at the threshold of standardness.
Proposition 2. If
\[
\sum_{n \leq 0} \frac{\ln(r_n)}{\ell_n} = +\infty \quad (-\Delta)
\]
and
\[
\lim_{n \to -\infty} \frac{\ln(r_n)}{\ell_n} = 0 \quad (\square),
\]
then any split-words filtration with lengths \((\ell_n)_{n \leq 0}\) is standard but cannot be extracted from a split-words filtration at the threshold of standardness.

One could think that the threshold of standardness is a kind of boundary between standardness and non-standardness. Yet, the situation is not so simple. Indeed, proposition 2 provides an example (example 3) of two split-words filtrations, where

- the first one is non-standard,
- the second one is standard,
- the second one is extracted from the first one,
- yet, no intermediate filtration (for extraction) is at the threshold of standardness.

Furthermore, we provide an example of a non-standard split-words filtration from which no filtration at the threshold of standardness can be extracted (example 9). The proof relies on theorem A below.

Recall that, given any filtration \((\mathcal{F}_n)_{n \leq 0}\) and an infinite subset \(B\) of \(\mathbb{Z}^-\), the extracted filtration \((\mathcal{F}_n)_{n \in B}\) is standard if and only if the complement \(B^c = \mathbb{Z}^- \setminus B\) is large enough in a certain way. Here, the meaning of “large enough” depends on the filtration \(\mathcal{F}\) considered. When \(\mathcal{F}\) is at the threshold of standardness, “large enough” means exactly “infinite”. But various types of transition from non-standardness to standardness are possible, and the next theorem provides some other possible conditions.

**Theorem A.** Let \((\alpha_n)_{n \leq 0}\) be any sequence of non-negative real numbers. There exists a split-words filtration \((\mathcal{F}_n)_{n \leq 0}\) such that for every infinite subset \(B\) of \(\mathbb{Z}^-\), the extracted filtration \((\mathcal{F}_n)_{n \in B}\) is standard if and only if
\[
\sum_{n \in B^c} \alpha_n = +\infty \quad \text{or} \quad \sum_{n \leq 0} 1_{[n \notin B, n+1 \notin B]} = +\infty.
\]

Theorem A immediately provides other interesting examples. For example, it may happen that \((\mathcal{F}_{2n})_{n \leq 0}\) is standard while \((\mathcal{F}_{2n-1})_{n \leq 0}\) is not, or vice versa. When this phenomenon occurs, we will say that the filtration \((\mathcal{F}_n)_{n \leq 0}\) “interlinks” standardness and non-standardness.

Repeated interlinking is possible. By suitably slowing time suitably in a filtration at the threshold of standardness (example 11), one gets can a filtration \((\mathcal{F}_n)_{n \leq 0}\) such that \((\mathcal{F}_{2n})_{n \leq 0}\), \((\mathcal{F}_{4n})_{n \leq 0}\), \((\mathcal{F}_{8n})_{n \leq 0}\),... are non-standard, whereas \((\mathcal{F}_{2n+1})_{n \leq 0}\), \((\mathcal{F}_{4n+2})_{n \leq 0}\), \((\mathcal{F}_{8n+4})_{n \leq 0}\),... are standard.
Improving on an example of Tsirelson  In a second part, we study another type of filtrations inspired by a construction of Tsirelson in unpublished notes [9].

Tsirelson has constructed an inhomogeneous discrete Markov process \((Z_n)_{n \leq 0}\) such that the random variables \((Z_{2n})_{n \leq 0}\) are independent and such that the natural filtration \((\mathcal{F}_n^Z)_{n \leq 0}\) is non-standard although its tail \(\sigma\)-field is trivial. This example is illuminating since “simple” reasons explain why the standardness criteria do not hold and no technical estimates are required. Tsirelson’s construction relies on a particular structure of the triples \((Z_{2n-2}, Z_{2n-1}, Z_{2n})\) that we explain. We call “bricks” these triples.

In this paper, we give a modified and simpler construction which provides stronger results by requiring more on the bricks: in our construction, for every \(n \leq 0\), \(Z_{2n-2}\) is a deterministic function of \(Z_{2n-1}\) and \(Z_{2n-1}\) is a deterministic function of \((Z_{2n-2}, Z_{2n})\), hence the filtration \((\mathcal{F}_n^Z)_{n \leq 0}\) is generated by the sequence \((Z_{2n})_{n \leq 0}\) of independent random variables. Yet, \((\mathcal{F}_n^Z)_{n \leq 0}\) is not standard. Thus the filtration \(\mathcal{F}_n^Z\) “interlinks” standardness and non-standardness. Actually, we have a complete characterisation of the standard filtrations among the filtrations extracted from \(\mathcal{F}_n^Z\).

Theorem B. There exists a Markov process \((Z_n)_{n \leq 0}\) such that

- for each for \(n \leq 0\), \(Z_n\) takes its values in some finite set \(F_n\).
- the random variables \((Z_{2n})_{n \leq 0}\) are independent.
- for each for \(n \leq 0\), \(Z_{2n-1}\) is a measurable deterministic function of \((Z_{2n-2}, Z_{2n})\).
- the filtration \((Z_n)_{n \leq 0}\) is \((r_n)_{n \leq 0}\)-adic for some sequence \((r_n)_{n \leq 0}\).
- for any infinite subset \(D\) of \(\mathbb{Z}_-\), the filtration \((\mathcal{F}_n^Z)_{n \in D}\) is standard if and only if \(2n - 1 \notin D\) for infinitely many \(n \leq 0\).

In particular, the filtration \((\mathcal{F}_n^Z)_{n \leq 0}\) is at the threshold of standardness.

In this theorem, the statement that \((\mathcal{F}_n^Z)_{n \leq 0}\) is at the threshold of standardness cannot be deduced from the standardness of \((\mathcal{F}_n^Z)_{n \leq 0}\) and the non-standardness of \((\mathcal{F}_n^Z)_{n \leq 0}\) only. Indeed, the example of repeated interlinking mentioned above (see example 11 in section 1) provides a counterexample (modulo a time-translation). The proof that \((\mathcal{F}_n^Z)_{n \leq 0}\) is at the threshold of standardness actually uses the fact that \((Z_n)_{n \leq 0}\) is an inhomogeneous Markov process.

1 The case of split-words filtrations

In the whole section, excepted in subsection 1.5, \(\mathcal{F} = (\mathcal{F}_n)_{n \leq 0}\) denotes a split-words filtration associated to a finite alphabet \(A\) (endowed with the uniform measure) and a decreasing sequence \((\ell_n)_{n \leq 0}\) of positive integers (the lengths) such that \(\ell_0 = 1\) and the ratios \(\alpha_n = \ell_{n-1}/\ell_n\) are integers.

First, we prove the characterisation at the threshold of standardness among the split-words filtrations stated in proposition 1.
1.1 Proof of proposition 1

**Preliminary observations**: let $B$ be an infinite subset of $\mathbb{Z}^-$ such that $B^c$ is infinite. Then the filtration $(F_n)_{n \in B}$ is a split-words filtration with lengths $(\ell_n)_{n \in B}$. The ratios between successive lengths are the integers $(R_n)_{n \in B}$ given by

$$R_n = \frac{\ell_{m(n)}}{\ell_n}$$

where $m(n) = \sup\{k < n : k \in B\}$.

Set $B_1 = B \cap (1 + B)$ and $B_2 = B \setminus (1 + B)$. Then $B_2$ is infinite and

- for $n \in B_1$, $R_n = r_n$,
- for $n \in B_2$, $R_n \geq r_n r_{n-1}$.

Furthermore, if $B^c$ does not contain two consecutive integers, then for any $n \in B_2$, one has $n - 2 \in B$ since $n - 1 \notin B$, thus $m(n) = n - 2$ and $R_n = r_n r_{n-1}$.

**Proof of the "if" part**: assume that

$$\sum_{n \leq 0} \frac{\log(r_n)}{\ell_n} < +\infty \text{ and } \inf_{n \leq 0} \frac{\log(r_n r_{n-1})}{\ell_n} > 0.$$  

The first condition $(\Delta)$ ensures that $F$ is not standard. Let $B$ be an infinite subset of $\mathbb{Z}^-$ such that $B^c$ is infinite. One has

$$\sum_{n \in B} \frac{\log(R_n)}{\ell_n} \geq \sum_{n \in B_2} \frac{\log(R_n)}{\ell_n} \geq \sum_{n \in B_2} \frac{\log(r_n r_{n-1})}{\ell_n} = +\infty,$$

since $B_2$ is infinite and $\inf\{(\log(r_n r_{n-1}))/\ell_n : n \leq 0\} > 0$. Thus, the split-words filtration $(F_n)_{n \in B}$ is standard since the sequence of lengths $(\ell_n)_{n \in B}$ fulfils condition $-(\Delta)$. Therefore $F$ is at the threshold of standardness.

**Proof of the "only if" part**: condition $(\Delta)$, which is equivalent to the non-standardness of $F$, is necessary for $F$ to be at the threshold of standardness. Let us show that if $(\Delta)$ and $-(*)$ hold, then $F$ is not at the threshold of standardness. Since the reals $\log(r_n r_{n-1})/\ell_n$ are positive, condition $-(*)$ induces the existence of a subsequence $(\log(r_{\phi(n)} r_{\phi(n)-1})/\ell_{\phi(n)})_{n \leq 0}$ such that

$$\forall n \in \mathbb{Z}^-, \quad \frac{\log(r_{\phi(n)} r_{\phi(n)-1})}{\ell_{\phi(n)}} \leq 2^n \quad \text{and} \quad \phi(n - 1) \leq \phi(n) - 2.$$  

Set $B = (\phi(\mathbb{Z}^-) - 1)^c$. Let us show that the filtration $(F_n)_{n \in B}$ is not standard. By construction, $\phi(\mathbb{Z}^-)$ is infinite and does not contain two consecutive integers. Hence $B$ and $(B)^c$ are both infinite and $B_2 = B \setminus (B + 1) = \phi(\mathbb{Z}^-)$. Moreover, according to the preliminary observations, $R_n = r_n$ for every $n \in B_1$ and $R_n = r_n r_{n-1}$ for every $n \in B_2$ since $B^c$ does not contain two consecutive integers. Thus

$$\sum_{n \in B} \frac{\log(R_n)}{\ell_n} = \sum_{n \in B_1} \frac{\log(r_n)}{\ell_n} + \sum_{n \in \phi(\mathbb{Z}^-)} \frac{\log(r_n r_{n-1})}{\ell_n} \leq \sum_{n \leq 0} \frac{\log(r_n)}{\ell_n} + \sum_{m \leq 0} 2^m < +\infty.$$  

Therefore $(F_n)_{n \in B}$ is not standard. Thus $F$ is not at the threshold of standardness.
1.2 Proof of proposition 2 and example

Proof. Assume that \((\neg \Delta)\) and \((\square)\) hold and that \(\mathcal{F}\) is extracted from some split-words filtration \(\mathcal{H}\) with lengths \((\ell'_n)_{n \leq 0}\), namely \(\mathcal{F}_n = \mathcal{H}_{\phi(n)}\) for every \(n \leq 0\), for some increasing map \(\phi\) from \(\mathbb{Z}^-\) to \(\mathbb{Z}^-\). Then for every \(n \leq 0\), \(\ell_n = \ell'_0(n)\) and \(r_n = r'_n \cdots r'_{\phi(n)-1+1}\) where \(r'_k = \ell'_{k-1}/\ell'_k\). Let us show that \(\mathcal{H}\) cannot be at the threshold of standardness.

Condition \((\neg \Delta)\) ensures that \(\mathcal{F}\) is standard. If \(\phi\) skips only finitely many integers, then \(\mathcal{H}\) is standard and the conclusion holds. Otherwise, \(\phi(u_n - 1) \leq \phi(u_n) - 2\) for infinitely many \(n\), and for those \(n\),

\[
\frac{\log(r'_n r'_{\phi(n)-1})}{\ell'_0(n)} \leq \frac{\log(r'_n \cdots r'_{\phi(n)-1+1})}{\ell'_0(n+1)} = \frac{\log r_n}{\ell_n}.
\]

Thus, \((\square)\) implies that

\[
\inf_{k \leq 0} \frac{\log(r'_k r'_{k-1})}{\ell'_k} = 0.
\]

Since the sequence \((r'_n)_{n \leq 0}\) does not fulfill condition \((\ast)\), \(\mathcal{H}\) is not at the threshold of standardness. \(\square\)

Example 3. Define the sequence of lengths \((\ell_n)_{n \leq 0}\) by \(\ell_0 = 1\), \(\ell_{-1} = 2\) and, for every \(n \leq -1\),

\[
\ell_{n-1} = \ell_n 2^{ \lfloor \ell_n/|n| \rfloor },
\]

where \(\lfloor x \rfloor\) denotes the integer part of \(x\).

A recursion shows that for every \(n \leq 0\), \(\ell_n\) is a power of 2, and that \(\ell_n \geq 2^{\lfloor |n| \rfloor} \geq |n|\), hence \(r_n = \ell_{n-1}/\ell_n \geq 2\). Moreover, for every \(n \leq -1\),

\[
\frac{\log_2(r_n)}{\ell_n} = \frac{\lfloor \ell_n/|n| \rfloor}{\ell_n} \in \left[ \frac{1}{2|n|}, \frac{1}{|n|} \right].
\]

Therefore, \((\neg \Delta)\) and \((\square)\) hold, hence \(\mathcal{F}\) is standard but cannot be extracted from any split-words filtration at the threshold of standardness.

Yet, since each \(\ell_n\) is a power of 2, \(\mathcal{F}\) is extracted from the dyadic split-words filtration \(\mathcal{H}\), which is not standard. Since every filtration extracted from \(\mathcal{H}\) is a split-words filtration, one can deduce that there is no intermediate filtration (for extraction) between \(\mathcal{H}\) and \(\mathcal{F}\).

Remark: there are trivial examples of standard split-words filtrations which cannot be extracted from any split-words filtration at the threshold of standardness. For example, consider any split-words filtrations such that \((\neg (\Delta))\) holds and such that \(r_n\) is a prime number for every \(n \leq 0\). The last condition prevents the filtration from being extracted from any other split-words filtration. Yet, it still could be extracted from some filtration at the threshold of standardness which is not a split-words filtration.

1.3 Proof of theorem A

Replacing \(\alpha_n\) by \(\min(\max(\alpha_n, 1/|n + 2|^2), 1)\) for \(n \leq -3\) does not change the nature of the series \(\sum_{k \in B^c} \alpha_k\), hence we may assume that for \(n \leq -3\),

\[
1/|n + 2|^2 \leq \alpha_n \leq 1.
\]
Set $\ell_0 = 1$, $\ell_{-1} = 2$, $\ell_{-2} = 8$, $\ell_{-3} = 64$, $\ell_{-4} = 2^{11} = 2048$ and $\ell_{n-2} = 2^{\lfloor \alpha_{n-1} \ell_n \rfloor}$ for every $n \leq -3$, where $\lfloor x \rfloor$ denotes the integer part of $x$. We begin with two technical lemmas.

**Lemma 4.** For every $n \leq -1$, $\ell_n \geq |n|^3$ and $\ell_n \geq 2|n+1|^2 \ell_{n+1}$.

**Proof of lemma 4.** The proof of lemma 4 is done by induction. One checks that the above inequalities hold for $-4 \leq n \leq -1$.

Fix some $n \leq -3$. Assume that the inequalities hold for $n+1$, $n$ and $n-1$. Then

$$\log_2 \ell_{n-2} - \log_2 \ell_{n-1} = \lfloor \alpha_{n-1} \ell_n \rfloor - \lfloor \alpha_n \ell_{n+1} \rfloor \geq \alpha_{n-1} \ell_n - \alpha_n \ell_{n+1} \geq \frac{\ell_n}{|n+1|^2} - \ell_{n+1} - 1 \geq \ell_{n+1} - 1 \quad \text{(since $\ell_n \geq 2|n+1|^2 \ell_{n+1}$)} \geq |n+1|^3 - 1 \quad \text{(since $\ell_{n+1} \geq |n+1|^3$)},$$

hence

$$\ell_{n-2}/\ell_{n-1} \geq 2^{\left( |n+1|^3 - 1 \right)} \geq 2|n-1|^2 \quad \text{(since $n \leq -3$)}.$$ 

Since $\alpha_{n-1} \geq |n-1|^3$, one has

$$\ell_{n-2} \geq 2|n-1|^2 \ell_{n-1} \geq 2|n-1|^5 \geq |n-2|^3 \quad \text{(since $n \leq -3$)}.$$

Thus the inequalities hold for $n-2$. The proof is complete.

**Lemma 5.** For every $n \leq -4$,

$$\frac{\log_2 \ell_{n-1}}{\ell_n} \leq \frac{1}{2|n+1|^2}, \quad \frac{\alpha_{n-1}}{2} \leq \frac{\log_2 \ell_{n-2}}{\ell_n} \leq \alpha_{n-1}, \quad \frac{\log_2 \ell_{n-3}}{\ell_n} \geq 1.$$

**Proof of lemma 5.** Fix $n \leq -4$. The assumptions made on the sequence $(\alpha_k)_{k \leq 0}$, and lemma 4 entail $\ell_n \alpha_{n-1} \geq |n|^3/|n+1|^2 \geq 1$, thus $\alpha_{n-1} \ell_n/2 \leq \lfloor \alpha_{n-1} \ell_n \rfloor \leq \alpha_{n-1} \ell_n$. Thus, the recursion formula $\ell_{n-2} = 2^{\lfloor \alpha_{n-1} \ell_n \rfloor}$ yields

$$\frac{\alpha_{n-1}}{2} \leq \frac{\log_2 \ell_{n-2}}{\ell_n} \leq \alpha_{n-1}.$$ 

Since $n \leq -4$, the same inequalities hold for $n+1$ and $n-1$, hence by lemma 4

$$\frac{\log_2 \ell_{n-1}}{\ell_n} \leq \frac{\ell_{n+1}}{\ell_n} \leq \frac{\ell_{n+1}}{\ell_n} \leq \frac{1}{2|n+1|^2},$$

and

$$\frac{\log_2 \ell_{n-3}}{\ell_n} \geq \frac{\alpha_{n-2} \ell_{n-1}}{2 \ell_n} \geq \frac{1}{2|n|^2} 2|n|^2 = 1.$$ 

The proof is complete.
We now prove theorem A.

Let us check that the split-words filtration associated to the to the lengths \((\ell_n)_{n \leq 0}\) fulfills the properties of the previous proposition.

Let \(B\) be an infinite subset of \(\mathbb{Z}^-\) such that \(B^c\) is infinite. Since replacing \(B\) by \(B \setminus \{-2, -1, 0\}\) does not change the nature of the filtration \((\mathcal{F}_n)_{n \in B}\), one may assume that \(B \subset (-\infty, -3]\).

Set \(m(n) = \sup\{k < n : k \in B\}\) for every \(n \leq 0\). Then \((\ell_{m(n)}/\ell_n)_{n \in B}\) is the sequence of ratios associated to the lengths \((\ell_n)_{n \in B}\). Since \((\Delta)\) characterises standardness of split-words filtrations,

\[
(\mathcal{F}_n)_{n \in B}\text{ is standard} \iff \sum_{n \in B} \log_2 (\ell_{m(n)}/\ell_n) = +\infty \iff \sum_{n \in B} \log_2 \ell_{m(n)}/\ell_n = +\infty,
\]

where the last equivalence follows from the convergence of the series \(\sum_n \log_2 \ell_n/\ell_n\) since \(\ell_n \geq 2^{2|n|}\) for every \(n \leq 0\).

Let us split \(B\) into three subsets:

- \(B_1 = \{n \in B : m(n) = n - 1\}\),
- \(B_2 = \{n \in B : m(n) = n - 2\}\),
- \(B_3 = \{n \in B : m(n) \leq n - 3\}\).

Then

\[
\sum_{n \in B} \log_2 \ell_{m(n)}/\ell_n = \sum_{n \in B_1} \log_2 \ell_{n-1}/\ell_n + \sum_{n \in B_2} \log_2 \ell_{n-2}/\ell_n + \sum_{n \in B_3} \log_2 \ell_{m(n)}/\ell_n.
\]

The inequality \(\ell_{m(n)} \geq \ell_{n-3}\) for \(n \in B_3\) and lemma 5 show that in the right-hand side,

- the first sum (over \(B_1\)) is always finite;
- the middle sum (over \(B_2\)) has the same nature as \(\sum_{n \in B_2} \alpha_n\);
- the last sum (over \(B_3\)) is finite if and only if \(B_3\) is finite.

When \(B_3\) is finite, any pair of consecutive integers excepted a finite number of them contain at least one element of \(B\). Hence, \((B_2 - 1)\) only differs from \(B^c\) by a finite set of integers. Thus the sum \(\sum_{n \in B_2} \alpha_n\) has the same nature as \(\sum_{n \in B^c} \alpha_n\). Theorem A follows.

### 1.4 Some applications of theorem A

Choosing particular sequences \((\alpha_n)_{n \leq 0}\) in theorem A provides interesting examples of non-standard filtrations. In what follows, \(\mathcal{F}\) denotes the filtration associated the sequence \((\alpha_n)_{n \leq 0}\) given by theorem A.

**Example 6.** If \(\alpha_n = 1\) for every \(n\), then \(\mathcal{F}\) is at the threshold of standardness.

**Example 7.** If \(\alpha_n = 0\) for every even \(n\) and \(\alpha_n = 1\) for every odd \(n\), then \((\mathcal{F}_{2n})_{n \leq 0}\) is standard whereas \((\mathcal{F}_{2n-1})_{n \leq 0}\) is not.
Example 8. If the series $\sum \alpha_n$ converges, then for every infinite subset $B$ of $\mathbb{Z}^-$, the extracted filtration $(F_n)_{n \in B}$ is standard if and only if $(B \cup (B - 1))^c$ is infinite. In particular, the filtrations $(F_{2n})_{n < 0}$ and $(F_{2n-1})_{n < 0}$ are at the threshold of standardness.

Example 9. If $\alpha_n \sim 1/|n|$ as $n$ goes to $-\infty$, then $F$ is not standard and no filtration at the threshold of standardness can be extracted from $F$.

**Proof of example 9.** The non-standardness of $F$ is immediate by theorem A.

Call $\mu$ the non-finite positive measure on $\mathbb{Z}^-$ defined by

$$\mu(B) = \sum_{n \in B} \alpha_n \text{ for } B \subset \mathbb{Z}^-.$$ 

Let $(F_n)_{n \in B}$ be any non-standard filtration extracted from $F$. We show that $(F_n)_{n \in B}$ cannot be at the threshold of standardness by constructing a subset $B'$ of $B$ such that $(F_n)_{n \in B'}$ is not standard although $B \setminus B'$ is finite.

By theorem A, we know that $\mu(B^c) < +\infty$ and

$$n \notin B \text{ and } n + 1 \notin B \text{ only for finitely many } n \in \mathbb{Z}^-.$$ 

Since $\mu(B^c)$ is finite, the elements of $B^c$ get rarer and rarer as $n \to -\infty$. In particular, the set $A = (B - 1) \cap B \cap (B + 1)$ is infinite.

We get $B'$ from $B$ by removing a “small” infinite subset of $A$. Namely, we set $B' = B \setminus A'$ where $A'$ is an infinite subset of $A$ which does not contain two consecutive integers and chosen such that $\mu(A') < +\infty$. By construction, $B \setminus B' = A'$ is infinite and $\mu((B')^c) < +\infty$ since $(B')^c = B^c \cup A'$. Thus $B'$ is an infinite subset of $B$.

Using the definition of $A$ and the fact that $A'$ does not contain two consecutive integers and by construction of $A$, one checks that $(B' \cup (B' - 1)) = (B \cup (B - 1))$, therefore $(B' \cup (B' - 1))^c$ is infinite.

Thus $(F_n)_{n \in B'}$ is not standard, which shows that $(F_n)_{n \in B}$ is not at the threshold of standardness.

1.5 Interlinking standardness and non standardness

Given any filtration $(F_n)_{n \leq 0}$, a simple way to get a “slowed” filtration is to repeat each $F_n$ some finite number of times, which may depend of $n$. We now show that this procedure does not change the nature of the filtration.

**Lemma 10.** Let $(F_n)_{n \leq 0}$ be any filtration and $\phi$ an increasing map from $\mathbb{Z}^-$ to $\mathbb{Z}^-$ such that $\phi(0) = 0$. For every $n \leq 0$, set $G_n = F_{\phi(k)}$ if $\phi(k) - 1 < n \leq \phi(k)$. Then:

- $(G_n)_{n \leq 0}$ is a filtration,
- $(F_n)_{n \leq 0}$ is extracted from $(G_n)_{n \leq 0},$
- $(G_n)_{n \leq 0}$ is standard if and only if $(F_n)_{n \leq 0}$ is standard.
Proof of lemma 10. By construction, $G_{\phi(k)} = F_k$ for every $k \leq 0$ and the sequence $(G_n)_{n \leq 0}$ is constant on every interval $[\phi(k-1) + 1, \phi(k)]$. The first two points follow.

The “only if” part of the third point is immediate since $F$ is extracted from $G$.

Assume that $F$ is standard. Then, up to an enlargement of the probability space, one may assume that $F$ is immersed in some product-type filtration $\mathcal{H}$. Define a slowed filtration by $K_n = H_k$ if $\phi(k-1) + 1 \leq n \leq \phi(k)$. Then $K$ is still a product-type filtration.

To prove that $G$ is immersed in $K$, we have to check that for every $n \leq -1$, $G_{n+1}$ and $K_n$ are independent conditionally on $G_n$. This holds in any case since:

- when $\phi(k-1) + 1 \leq n \leq \phi(k) - 1$, $G_{n+1} = F_k$, $K_n = H_k$ and $G_n = F_k$;
- when $n = \phi(k)$, $G_{n+1} = F_{k+1}$, $K_n = H_k$ and $G_n = F_k$.

Hence $G$ is standard.

Example 11. Assume that $(F_n)_{n \leq 0}$ is at the threshold of standardness. Set $\phi(0) = 0$, $\phi(-1) = -1$ and, for every $k \leq 0$, $\phi(2k) = -2^{|k|}$ and $\phi(2k+1) = -2^{|k|} - 1$. Let $G$ be the slowed filtration obtained from $F$ as above. Then for any $d \geq 1$, the filtration $(G_{2^d n})_{n \leq 0}$ is not standard, whereas the filtration $(G_{2^d n-2^d-1})_{n \leq 0}$ is standard.

Proof of example 11. Fix $d \geq 1$. The filtrations $(G_{2^d n})_{n \leq -2}$ and $(G_{2^d n-2^d-1})_{n \leq -1}$ can be obtained from $(F_n)_{n \leq -2d-2}$ and $(F_{2n-1})_{n \leq -d}$ by time-translations and by the slowing procedure just introduced. And truncations, time-translations and slowing procedure preserve the nature of the filtrations.

2 Improving on an example of Tsirelson

In some non-published notes, Tsirelson gives a method to construct an inhomogeneous Markov process $(X_n)_{n \leq 0}$ such that the natural filtration $(F_n)_{n \leq 0}$ is easily proved to be non-standard, although the tail $\sigma$-field $F_{-\infty}$ is trivial and the random variables $(X_{2n})_{n \leq 0}$ are independent.

In Tsirelson’s construction, each triple $(X_{2n-2}, X_{2n-1}, X_{2n})$ has a particular structure that we will explain soon. Since the sequence $(X_n)_{n \leq 0}$ is obtained by gluing the triples $(X_{2n-2}, X_{2n-1}, X_{2n})$ in a Markovian way, we call Tsirelson’s bricks these triples.

2.1 The basic Tsirelson’s brick

Informally, the basic brick in Tsirelson’s construction is a triple of uniform random variables $X_0, X_1, X_2$ with values in some finite sets $F_0, F_1, F_2$ such that for some $\alpha \in [0, 1]$,

- the set $F_2$ is arbitrarily large, and the set $F_0$ is much larger;
- the triple $(X_0, X_1, X_2)$ is Markov;
- the random variables $X_0$ and $X_2$ are independent;
- any two different values of $X_0$ lead to different values of $X_2$ with probability $\geq 1 - \alpha$. 

11
We now explain what the last requirement means.

Fix two distinct values in $F_0$, namely $x_0'$ and $x_0''$. Choose randomly but not necessarily independently $x_1'$ and $x_1''$ in $F_1$ according to the laws $\mathcal{L}(X_1|X_0 = x_0')$ and $\mathcal{L}(X_1|X_0 = x_0'')$. Then choose randomly but not necessarily independently $x_2'$ and $x_2''$ in $F_2$ according to the laws $\mathcal{L}(X_2|X_1 = x_1')$ and $\mathcal{L}(X_2|X_1 = x_1'')$. Then the values $x_2'$ and $x_2''$ must be different with probability $\geq 1 - \alpha$, whatever was the strategy used to make the different choices.

More precisely, note $\rho_2$ the discrete metric on $F_2$: for all $x_2'$ and $x_2''$ in $F_2$,

$$
\rho_2(x_2', x_2'') = 1 \quad \text{if} \quad x_2' \neq x_2'', \\
\rho_2(x_2', x_2'') = 0 \quad \text{if} \quad x_2' = x_2''.
$$

For all $x_1'$ and $x_1''$ in $F_1$, note $\rho_1(x_1', x_1'')$ the Kantorovitch-Rubinstein distance between the laws $\mathcal{L}(X_2|X_1 = x_1')$ and $\mathcal{L}(X_2|X_1 = x_1'')$. By definition,

$$
\rho_1(x_1', x_1'') = \inf\{E[\rho_2(X_2', X_2'')]; X_2' \sim \mathcal{L}(X_2|X_1 = x_1'), X_2'' \sim \mathcal{L}(X_2|X_1 = x_1'')\}.
$$

Since $\rho_2$ is the discrete metric on $F_2$, $\rho_1(x_1', x_1'')$ is actually the total variation distance between $\mathcal{L}(X_2|X_1 = x_1')$ and $\mathcal{L}(X_2|X_1 = x_1'')$.

By the same way, for all $x_0'$ and $x_0''$ in $F_0$, denote by $\rho_0(x_0', x_0'')$ the Kantorovitch-Rubinstein distance between the laws $\mathcal{L}(X_1|X_0 = x_0')$ and $\mathcal{L}(X_1|X_0 = x_0'')$. The last requirement means that $\rho_0(x_0', x_0'') \geq 1 - \alpha$ when $x_0' \neq x_0''$. This condition is used by Tsirelson to negate Vershik’s criterion.

Here is another formulation, which is closer to the I-cosiness criterion recalled in section 3: for any non-anticipative coupling of two copies $(X_0', X_1', X_2')$ and $(X_0'', X_1'', X_2'')$ of $(X_0, X_1, X_2)$, defined on some probability space $(\Omega, \mathcal{A}, \mathbb{P})$,

$$
\mathbb{P}[X_2' \neq X_2''|\sigma(X_0', X_0'')] \geq 1 - \alpha \quad \text{on the event} \quad [X_0' \neq X_0''].
$$

Here, the expression “non-anticipative” means that the filtrations generated by the processes $X'$ and by $X''$ are immersed in the natural filtration of $(X', X'')$. In particular, $X_1'$ and $X_0''$ are independent conditionally on $X_0'$ (the couple $(X_0', X_0'')$ gives no more information on $X_1'$ than $X_0'$ does). Similarly, $X_2'$ and $(X_0', X_0'')$ are independent conditionally on $(X_0', X_1')$. And the same holds when the roles of $X'$ and $X''$ are exchanged.

Let us give a formal definition.

**Definition 12.** Fix $\alpha \in [0, 1]$. Let $F_0, F_1, F_2$ be finite sets. We will say that a triple $(Z_0, Z_1, Z_2)$ of uniform random variables with values in $F_0, F_1, F_2$ is a Tsirelson’s $\alpha$-brick if

- the triple $(Z_0, Z_1, Z_2)$ is Markov.
- $Z_0$ and $Z_2$ are independent.
- for any non-anticipative coupling of two copies $(X_0', X_1', X_2')$ and $(X_0'', X_1'', X_2'')$ of $(X_0, X_1, X_2)$, defined on some probability space $(\Omega, \mathcal{A}, \mathbb{P})$,

$$
\mathbb{P}[X_2' \neq X_2''|\sigma(X_0', X_0'')] \geq 1 - \alpha \quad \text{on the event} \quad [X_0' \neq X_0''].
$$
2.2 Tsirelson’s example of a brick

Tsirelson gives an example of such a brick which is enlightening.

Let $p$ be a prime number, and $\mathbb{Z}_p$ be the finite field with $p$ elements. Note $F_0$ the set of all two-dimensional linear subspaces of $(\mathbb{Z}_p)^5$, $F_1$ the set of all one-dimensional affine subspaces of $(\mathbb{Z}_p)^5$ and $F_2 = (\mathbb{Z}_p)^5$. Then the size of $F_2$ is $|F_2| = p^5$ whereas

\[ |F_0| = \frac{(p^5 - 1)(p^5 - p)}{(p^2 - 1)(p^2 - p)} = (p^4 + p^3 + p^2 + p + 1)(p^2 + 1). \]

Indeed, the number of couples of independent vectors in $(\mathbb{Z}_p)^5$ is $(p^5 - 1)(p^5 - p)$, but any linear plane in $(\mathbb{Z}_p)^5$ can be generated by $(p^2 - 1)(p^2 - p)$ of these couples.

Tsirelson constructs a Markovian triple $(X_0, X_1, X_2)$ as follows:

- choose uniformly $X_0$ in $F_0$ ;
- given $X_0$, choose uniformly $X_1$ among the affine lines whose direction are included in the linear plane $X_0$ ;
- given $X_0$ and $X_1$, choose uniformly $X_2$ on the affine line $X_1$.

One can check that $X_2$ is uniform on $F_2$, and independent of $X_0$.

Now, let $(X'_0, X'_1, X'_2)$ and $(X''_0, X''_1, X''_2)$ be any non-anticipative coupling of two copies of $(X_0, X_1, X_2)$, defined on some probability space $(\Omega, \mathcal{A}, \mathbb{P})$. Then, conditionally on $(X'_0, X''_0, X'_1, X''_1)$, the law of $X'_2$ is uniform on the line $X'_1$ and the law of $X''_2$ is uniform on the $X''_1$. Since two distinct lines have at most one common point, one has

\[ \mathbb{P}[X'_2 = X''_2|\sigma(X'_0, X''_0, X'_1, X''_1)] \leq 1_{[X'_1 = X''_1]} + \frac{1}{p}1_{[X'_1 \neq X''_1]}, \]

hence

\[ \mathbb{P}[X'_2 \neq X''_2|\sigma(X'_0, X''_0, X'_1, X''_1)] \geq \frac{p - 1}{p}1_{[X'_1 \neq X''_1]}. \]

Similarly, conditionally on $(X'_0, X''_0)$, the law of $X'_1$ is uniform on the set of all affine lines which are parallel to $X'_0$ and the law of $X''_1$ is uniform on the set of all affine lines which are parallel to $X''_0$. But the affine lines $X'_1$ and $X''_1$ must have the same direction to be equal. Since each linear plane in $(\mathbb{Z}_p)^5$ contains $p + 1$ linear lines whereas two distinct planes contain at most one common line,

\[ \mathbb{P}[X'_1 = X''_1|\sigma(X'_0, X''_0)] \leq 1_{[X'_0 = X''_0]} + \frac{1}{p + 1}1_{[X'_0 \neq X''_0]}, \]

hence

\[ \mathbb{P}[X'_1 \neq X''_1|\sigma(X'_0, X''_0)] \geq \frac{p}{p + 1}1_{[X'_0 \neq X''_0]}. \]

Putting things together, one gets

\[ \mathbb{P}[X'_2 \neq X''_2|\sigma(X'_0, X''_0)] \geq \frac{p - 1}{p} \mathbb{P}[X'_1 \neq X''_1|\sigma(X'_0, X''_0)] \]

\[ \geq \frac{p - 1}{p + 1}1_{[X'_0 \neq X''_0]}. \]

Hence, $(X_0, X_1, X_2)$ is a Tsirelson’s $\alpha$-brick with $\alpha = 2/(p + 1)$. 

13
2.3 Assembling bricks together

The next step is to construct a non-homogeneous Markov process \((X_n)_{n \leq 0}\) such that for each \(n \leq 0\), the subprocess \((X_{2n-2}, X_{2n-1}, X_{2n})\) is an Tsirelson’s \(\alpha_n\)-brick, where the \([0,1]-valued sequence \((\alpha_n)_{n \leq 0}\) fulfills

\[
\sum_{n \leq 0} \alpha_n < +\infty.
\]

The next theorem achieves Tsirelson’s construction.

**Theorem C.** Let \((X_n)_{n \leq 0}\) be a sequence of uniform random variables with values in finite sets \((F_n)_{n \leq 0}\) and \((\alpha_n)_{n \leq 0}\) be an \([0,1]-valued sequence such that the series \(\sum_n \alpha_n\) converges. Assume that

- the sets \(F_{2n}\) are not singles,
- \((X_n)_{n \leq 0}\) is a non-homogeneous Markov process,
- for each \(n \leq 0\), the subprocess \((X_{2n-2}, X_{2n-1}, X_{2n})\) is a Tsirelson’s \(\alpha_n\)-brick.

Then the natural filtration \(\mathcal{F}^X\) is not standard. Moreover, if the tail \(\sigma\)-field \(\mathcal{F}^X\) is trivial, then \(|F_{2n}| \to +\infty\) as \(n \to -\infty\).

**Proof of theorem C.** First, we show that \(X_0\) does not fulfills the I-cosiness criterion (see section 3). Indeed, set

\[
c = \prod_{k \leq 0} (1 - \alpha_k) > 0
\]

and consider any non-anticipative coupling \((X'_n)_{n \leq 0}\) and \((X''_n)_{n \leq 0}\) of the process \((X_n)_{n \leq 0}\), defined on some probability space \((\Omega, \mathcal{A}, \mathbb{P})\). By assumption, for every \(n \leq 0\),

\[
\mathbb{P}[X'_{2n} \neq X''_{2n} | \sigma(X'_{2n-2}, X''_{2n-2})] \geq (1 - \alpha_n) \mathbf{1}_{[X'_{2n-2} \neq X''_{2n-2}]}.
\]

By induction, for every \(n \leq 0\),

\[
\mathbb{P}[X'_0 \neq X''_0 | \sigma(X'_2, X''_2)] \geq \left( \prod_{k=n+1}^{0} (1 - \alpha_k) \right) \mathbf{1}_{[X'_2 \neq X''_2]} \geq \mathbf{1}_{[X'_2 \neq X''_2]}
\]

If, for some \(N \leq 0\), the \(\sigma\)-fields \(\mathcal{F}^X_{2N}\) and \(\mathcal{F}^X_{2N}\) are independent, then

\[
\mathbb{P}[X'_0 \neq X''_0] \geq \mathbb{P}[X'_0 \neq X''_0] \geq c |F_{2n}|^{-1} \geq c/2.
\]

Hence \(\mathbb{P}[X'_0 \neq X''_0]\) is bounded away from 0, which negates the I-cosiness criterion. The non-standardness of \(\mathcal{F}^X\) follows.

The second part of the theorem directly follows from the next proposition, applied to the sequence \((Y_n)_{n \leq 0} = (X_{2n})_{n \leq 0}\).

**Proposition 13.** Let \((\gamma_n)_{n \leq 0}\) be a sequence of positive constants such that

\[
\prod_{n \leq 0} \gamma_n > 0.
\]
Let \((Y_n)_{n\leq 0}\) be a family of random variables which are uniformly distributed on finite sets \((E_n)_{n\leq 0}\). Let \((Y'_n)_{n\leq 0}\) and \((Y''_n)_{n\leq 0}\) be independent copies of the process \((Y_n)_{n\leq 0}\), defined on some probability space \((\Omega, \mathcal{A}, \mathbb{P})\). Assume that \(\mathcal{F}^Y_{-\infty}\) is trivial and that for every \(n \leq 0\),
\[
\mathbb{P}[Y'_n \neq Y''_n | \sigma(Y_{n-1}, Y''_{n-1})] \geq \gamma_n \mathbb{1}[Y'_n \neq Y''_{n-1}].
\]
Then \(|E_n| \to 1\) or \(|E_n| \to +\infty\) as \(n \to -\infty\).

**Proof of proposition 13.** By the independence of \((Y'_n)_{n\leq 0}\) and \((Y''_n)_{n\leq 0}\), the following exchange properties apply (see [11])
\[
\bigcap_{m \leq 0} \bigcap_{n \leq 0} \left( \mathcal{F}^Y_{m} \vee \mathcal{F}^{Y''}_{n} \right) = \bigcap_{m \leq 0} \left( \mathcal{F}^Y_{m} \vee \left( \bigcap_{n \leq 0} \mathcal{F}^{Y''}_{n} \right) \right)
\]
\[
= \bigcap_{m \leq 0} \left( \mathcal{F}^Y_{m} \vee \mathcal{F}^{Y''}_{-\infty} \right)
\]
\[
= \left( \bigcap_{m \leq 0} \mathcal{F}^Y_{m} \right) \vee \mathcal{F}^{Y''}_{-\infty}
\]
\[
= \mathcal{F}^Y_{-\infty} \vee \mathcal{F}^{Y''}_{-\infty}.
\]
Using that \(\mathcal{F}^Y_{m} \vee \mathcal{F}^{Y''}_{n}\) is non-decreasing with respect to \(m\) and \(n\), one gets
\[
(\mathcal{F}^Y \vee \mathcal{F}^{Y''})_{-\infty} = \bigcap_{n \leq 0} \left( \mathcal{F}^Y_{n} \vee \mathcal{F}^{Y''}_{n} \right) = \bigcap_{m \leq 0} \bigcap_{n \leq 0} \left( \mathcal{F}^Y_{m} \vee \mathcal{F}^{Y''}_{n} \right).
\]
Hence the tail \(\sigma\)-field \((\mathcal{F}^Y \vee \mathcal{F}^{Y''})_{-\infty}\) is trivial. Thus the asymptotic event
\[
\liminf_{n \to -\infty} [Y'_n \neq Y''_n]
\]
has probability 0 or 1.

But a recursion shows that for every \(n \leq 0\)
\[
\mathbb{P} \left( \bigcap_{n \leq k \leq 0} [Y'_k \neq Y''_k] \bigg| \sigma(Y'_n, Y''_n) \right) \geq \left( \prod_{n+1 \leq k \leq 0} \gamma_k \right) \mathbb{1}[Y'_n \neq Y''_n].
\]
By taking expectations,
\[
\mathbb{P} \left( \bigcap_{n \leq k \leq 0} [Y'_k \neq Y''_k] \right) \geq (1 - |E_n|^{-1}) \prod_{n+1 \leq k \leq 0} \gamma_k.
\]
If \(|E_n| \geq 2\) for infinitely many \(n \leq 0\), then
\[
\mathbb{P} \left( \bigcap_{k \leq 0} [Y'_k \neq Y''_k] \right) \geq \frac{1}{2} \prod_{k \leq 0} \gamma_k > 0.
\]
Thus \(|E_n| \geq 2\) for every \(n \leq 0\) and
\[
\mathbb{P} (\liminf_{n \to -\infty} [Y'_n \neq Y''_n]) = 1.
\]
But by Fatou's lemma,
\[
\mathbb{P} (\liminf_{n \to -\infty} [Y'_n \neq Y''_n]) \leq \liminf_{n \to -\infty} \mathbb{P}[Y'_n \neq Y''_n].
\]
Hence \(1 - |E_n|^{-1} = \mathbb{P}[Y'_n \neq Y''_n] \to 1\) thus \(|E_n| \to +\infty\) as \(n \to -\infty\).
Choosing the size of the sets $F_n$

The last theorem explains the necessity to have bricks $(Z_0, Z_1, Z_2)$ such that the set $F_2$ of all possible values of $Z_2$ is arbitrarily large, and the set $F_0$ of all possible values of $Z_0$ is much larger. In Tsirelson’s example, the size of $F_2$ is $p^5$ where $p$ is a prime number, whereas the size of $F_0$ is $(p^4 + p^3 + p^2 + p + 1)(p^2 + 1)$.

Such bricks provided cannot be glued together since the size of $F_2$ is not a power of a prime number: it has at least two prime divisors since the greatest common divisor of $p^4 + p^3 + p^2 + p + 1$ and $p^2 + 1$ is 1. Replacing $Z_p$ by a more general finite field would not change anything since the size of any finite field is necessarily a power of a prime number. Fortunately, a slight modification solve this problem.

A first way to solve the problem is to choose a prime number $q$ such that $q^5$ is slightly smaller than $(p^4 + p^3 + p^2 + p + 1)(p^2 + 1)$ and to call $F_0$ a subset with size $q^5$ of all two-dimensional linear subspaces of $(Z_p)^5$. After this modification, the law of $Z_1$ (a random line choose uniformly along the affine lines which are parallel to the linear plane $Z_0$) will no longer be an uniform law, but the law of $Z_1$ plays no particular role in the construction.

A second solution is to replace the affine lines by the affine planes in the definition of $Z_1$ and $F_1$. In this last solution, $Z_0$ is a deterministic function of $Z_1$ (namely, the vector plane is the direction of the affine plane) and $Z_1$ is a deterministic function of $(Z_0, Z_2)$ (namely, $Z_1$ is the only affine plane which is parallel to $Z_0$ and contains $Z_2$). These two additional properties have many advantages. First, the construction and the proofs are even simpler. Next, we will use them to get stronger results.

From now on, we will consider only bricks having these two additional properties.

Strong bricks

Let us give a rigorous definition.

**Definition 14.** Fix $\alpha \in [0,1]$ and two positive integers $r_1,r_2$. Let $F_0,F_1,F_2$ be finite sets. We will say that a triple $(Z_0,Z_1,Z_2)$ of uniform random variables with values in $F_0,F_1,F_2$ is a strong $(r_1,r_2)$-adic $\alpha$-brick if

- $Z_0$ and $Z_2$ are independent.
- $Z_1$ is a deterministic function of $(Z_0, Z_2)$;
- $Z_0$ is a deterministic function of $Z_1$;
- the conditional law of $Z_1$ given $Z_0$ is uniform on some finite random set of size $r_1$;
- the conditional law of $Z_2$ given $Z_1$ is uniform on some finite random set of size $r_2$;
- for every distinct elements $z_1'$ and $z_1''$ in $F_1$,

$$\sum_{z \in F_2} \min \left( \mathbb{P}[Z_2 = z | Z_1 = z_1'], \mathbb{P}[Z_2 = z | Z_1 = z_1''] \right) \leq \alpha. \quad (1)$$

The next lemma shows that the definition of strong bricks is more restrictive that the definition of Tsirelson’s bricks.
Lemma 15. If \((Z_0, Z_1, Z_2)\) is a strong \(\alpha\)-brick, then for any non-anticipative coupling \((Z'_0, Z'_1, Z'_2)\) and \((Z''_0, Z''_1, Z''_2)\) of \((Z_0, Z_1, Z_2)\), defined on some probability space \((\Omega, \mathcal{A}, \mathbb{P})\),

\[
\mathbb{P}[Z'_2 \neq Z''_2 | \sigma(Z'_1, Z'_1)] \geq (1 - \alpha)\mathbb{1}_{[Z'_1 \neq Z''_1]} \geq (1 - \alpha)\mathbb{1}_{[Z'_0 \neq Z''_0]}.
\]

Thus, \((Z_0, Z_1, Z_2)\) is a Tsirelson’s \(\alpha\)-brick

Proof of lemma 15. The triple \((Z_0, Z_1, Z_2)\) is Markov since \(Z_0\) is a function of \(Z_1\). Now, let \((Z'_0, Z'_1, Z'_2)\) and \((Z''_0, Z''_1, Z''_2)\) be any non-anticipative coupling of \((Z_0, Z_1, Z_2)\), defined on some probability space \((\Omega, \mathcal{A}, \mathbb{P})\). Set \(\mathcal{G} = \sigma(Z'_0, Z'_1, Z'_2, Z''_2)\). By the non-anticipative and the Markov properties,

\[
\mathcal{L}(Z'_2|\mathcal{G}) = \mathcal{L}(Z'_2|\sigma(Z'_0, Z'_1)) = \mathcal{L}(Z'_2|\sigma(Z'_1))
\]

and the same holds with \(Z''_2\).

Thus for any distinct values \(z', z''\) in \(F_1\), one has, on the event \([Z'_1 = z' ; Z''_1 = z'']\),

\[
\mathbb{P}[Z'_2 = Z''_2|\mathcal{G}] = \sum_{z \in F_2} \mathbb{P}[Z'_2 = z ; Z''_2 = z|\mathcal{G}] \\
\leq \sum_{z \in F_2} \mathbb{P}[Z'_{2n} = z|\mathcal{G}] \land \mathbb{P}[Z''_2 = z|\mathcal{G}] \\
= \sum_{z \in F_2} \mathbb{P}[Z'_2 = z|Z'_1 = z'] \land \mathbb{P}[Z''_2 = z|Z''_1 = z''] \\
= \sum_{z \in F_2} \mathbb{P}[Z_2 = z|Z_1 = z'] \land \mathbb{P}[Z_2 = z|Z_1 = z''] \\
\leq \alpha.
\]

Hence

\[
\mathbb{P}[Z'_2 = Z''_2|\mathcal{G}] \leq \alpha \mathbb{1}_{[Z'_1 \neq Z''_1]} + \mathbb{1}_{[Z'_1 = Z''_1]}.
\]

Taking complements, one gets

\[
\mathbb{P}[Z'_2 \neq Z''_2|\mathcal{G}] \geq (1 - \alpha)\mathbb{1}_{[Z'_1 \neq Z''_1]}.
\]

The last inequality follows from the inclusion \([Z'_0 \neq Z''_0] \subset [Z'_1 \neq Z''_1]\).

As we now see, the definition of a strong brick provides constraints on the size of the sets \(F_0, F_1, F_2\).

Lemma 16. (Properties of bricks) Fix \(\alpha \in [0, 1]\) and two positive integers \(r_1, r_2\). Let \(F_0, F_1, F_2\) be finite sets. Assume the existence of a triple \((Z_0, Z_1, Z_2)\) of uniform random variables with values in \(F_0, F_1, F_2\) such that \((Z_0, Z_1, Z_2)\) is a \((r_1, r_2)\)-adic \(\alpha\)-brick. Let \(f : F_1 \rightarrow F_0\) and \(g : F_0 \times F_2 \rightarrow F_1\) be the maps such that \(f(Z_1) = Z_0\) and \(g(Z_0, Z_2) = Z_1\). Then:

1. the map \(f\) is \(r_1\) to one and the map \(g\) is \(r_2\) to one. More precisely, for every \(z_1 \in F_1\), \(g^{-1}(\{z_1\}) = \{f(z_1)\} \times S(z_1)\) where \(S(z_1)\) is a subset of \(F_2\) of size \(r_2\).
2. for every \(z_1 \in F_1\), the law of \(Z_2\) conditionally on \(Z_1 = z_1\) is uniform on \(S(z_1)\).
3. for each \(z_0 \in F_0\), the subsets \(S(z_1)\) for \(z_1 \in f^{-1}(\{z_0\})\) form a partition of \(F_2\) in \(r_1\) blocks.
4. \(|F_1| = r_1|F_0|, |F_0 \times F_2| = r_2|F_1|\) and \(|F_2| = r_1r_2\).

5. for every distinct elements \(z'_1\) and \(z''_1\) in \(F_1\), \(|S(z'_1) \cap S(z''_1)| \leq \alpha r_2\).

6. if \(|F_0| \geq 2\), then \(r_2 \geq 1/\alpha\).

**Proof of lemma 16.** By hypothesis, for every \((z_0, z_1, z_2) \in F_0 \times F_1 \times F_2\),

\[
P[Z_0 = z_0; Z_1 = z_1] = \frac{1}{|F_1|} 1_{z_0 = f(z_1)}.
\]

Hence

\[
P[Z_1 = z_1|Z_0 = z_0] = \frac{1}{|f^{-1}(\{z_0\})|} 1_{f^{-1}(\{z_0\})(z_1)},
\]

which shows that \(|f^{-1}(\{z_0\})| = r_1\).

By the same way,

\[
P[Z_0 = z_0; Z_1 = z_1; Z_2 = z_2] = \frac{1}{|F_0 \times F_2|} 1_{z_1 = g(z_0, z_2)}.
\]

Hence

\[
P[Z_0 = z_0; Z_2 = z_2|Z_1 = z_1] = \frac{1}{|g^{-1}(\{z_1\})|} 1_{g^{-1}(\{z_1\})(z_0, z_2)},
\]

which shows that \(|g^{-1}(\{z_1\})| = r_2\).

Since \((Z_0, Z_2)\) is uniform on \(F_0 \times F_2\), the equalities \(Z_0 = f(Z_1)\) and \(Z_1 = g(Z_0, Z_2)\) shows that \(z_0 = f(g(z_0, z_2))\) for every \((z_0, z_2) \in F_0 \times F_2\). Hence, for every \(z_1 \in F_1\), if \((z_0, z_2) \in g^{-1}(\{z_1\})\) then \(z_0 = f(z_1)\). This shows that \(g^{-1}(\{z_1\}) = \{f(z_1)\} \times S(z_1)\) where \(S(z_1)\) is some subset of \(F_2\).

Thus, for every \((z_1, z_2) \in F_1 \times F_2\),

\[
P[Z_2 = z_2|Z_1 = z_1] = \frac{1}{|S(z_1)|} 1_{S(z_1)}(z_2).
\]

Hence the law of \(Z_2\) conditionally on \(Z_1 = z_1\) is uniform on \(S(z_1)\) which has size \(r_2\). This completes the proof of the first two points.

The third and fourth points follow.

Fix two distinct elements \(z'_1\) and \(z''_1\) in \(F_1\). Then for every \(z \in F_2\),

\[
\min\left(P[Z_2 = z|Z_1 = z'_1], P[Z_2 = z|Z_1 = z''_1]\right) = \frac{1}{r_2} \min(1_{S(z'_1)}(z), 1_{S(z''_1)}(z)).
\]

Summing over \(z\) and using the inequality 1, one gets

\[|S(z'_1) \cap S(z''_1)| \leq \alpha r_2,\]

which is the fifth point.

If \(|F_0| \geq 2\), then one can choose two distinct elements \(z'_0\) and \(z''_0\) in \(F_0\). Let \(z_2 \in F_2\), \(z'_1 = g(z'_0, z_2)\) and \(z''_1 = g(z''_0, z_2)\). Then \(z'_1\) and \(z''_1\) are distinct elements in \(F_1\) since \(f(z'_1) = z'_0\) and \(f(z''_1) = z''_0\) are distinct. But \(z_2\) belongs to \(S(z'_1)\) since

\[
P[Z_1 = z'_1|Z_2 = z_2] = P[Z_0 = z'_0|Z_2 = z_2] = |F_0|^{-1},
\]

and \(z_2\) also belongs to \(S(z''_1)\). Hence \(1 \leq |S(z'_1) \cap S(z''_1)| \leq \alpha r_2\), which shows the sixth point. \(\square\)
2.6 Getting bricks

The next lemma provides a general method to get bricks.

Lemma 17. (Method to get bricks)

Fix $\alpha \in ]0, 1]$ and two positive integers $r_1, r_2$.

Let $F_0, F_2$ be finite sets such that $F_2$ has size $r_1 r_2$.

Let $Z_0$ and $Z_2$ be independent random variables, uniformly distributed in $F_0$ and $F_2$.

Let $(\Pi_z)_{z \in F_0}$ be a family of partitions of $F_2$ indexed by $F_0$ such that

- each partition $\Pi_z$ has $r_1$ blocks $S_{z,1}, \ldots, S_{z,r_1}$;
- each block has $r_2$ elements.
- for any distinct $(z', i')$ and $(z'', i'')$ in $F_0 \times [1, r_1]$, $|S_{z',i'} \cap S_{z'',i''}| \leq \alpha r_2$.

(This "transversality condition" forces the partitions to be all different and says that two blocks chosen in any two different partitions have a small intersection.)

Define a random variable with values in $F_1 = F_0 \times [1, r_1]$ by $Z_1 = (Z_0, J)$, where $J$ is the index of the only block of $\Pi_{Z_0}$ which contains $Z_2$ (that is to say $Z_2 \in S_{Z_0, J}$).

Then $(Z_0, Z_1, Z_2)$ is a $(r_1, r_2)$-adic $\alpha$-brick.

Proof of lemma 17. The first statement is obvious.

For every $z_0 \in F_0$, $j \in [1, r_1]$ and $z_2 \in F_2$,

$$
\mathbb{P}[Z_0 = z_0 \ ; \ J = j \ ; \ Z_2 = z_2] = 1_{[z_0 \in S_{j,0,j}]} \mathbb{P}[Z_0 = z_0 \ ; \ Z_2 = z_2] = 1_{[z_2 \in S_{j,0,j}]} \times \frac{1}{|F_0|} \times \frac{1}{r_1 r_2}.
$$

Summing over $z_2$ yields

$$
\mathbb{P}[Z_0 = z_0 \ ; \ J = j] = \frac{1}{|F_0|} \times \frac{1}{r_1}.
$$

By division, one gets

$$
\mathbb{P}[Z_2 = z_2 \mid Z_0 = z_0 \ ; \ J = j] = 1_{[z_2 \in S_{j,0,j}]} \times \frac{1}{r_1}.
$$

The last two equalities show that $J$ is independent of $Z_0$ and uniform on $[1, r_1]$, and that given $(Z_0, J)$, $Z_2$ is uniform on the block $S_{Z_0, J}$. This proves the third and the fourth statement.

Let $z'_1$ and $z''_1$ be distinct elements in $F_1$. Conditionally on $[Z_1 = z'_1]$, the law $Z_2$ is uniform on the block $S_{z'_1}$. Conditionally on $[Z_1 = z''_1]$, the law $Z_2$ is uniform on the block $S_{z''_1}$. Thus

$$
\sum_{z \in F_2} \mathbb{P}[Z_2 = z \mid Z_1 = z'_1] \wedge \mathbb{P}[Z_2 = z \mid Z_1 = z''_1] = \sum_{z \in S_{z'_1} \cap S_{z''_1}} \frac{1}{r_2} \leq \alpha.
$$

The last statement follows. \qed
2.7 Examples of bricks

Algebra helps us to construct many partitions on a given set such that each partition has a fix number of blocks, each block has a fix number of elements and any two blocks chosen in any two different partitions have a small intersection.

Let $q$ be any power of a prime number. Let $K$ be the field with $q$ elements, and $L$ the field with $q^2$ elements. Since $L$ is a quadratic extension of $K$, $L$ is isomorphic to $K^2$ as a vector space on $K$. Actually, one only needs to have a bijection between $K^2$ and $L$.

First example

We set $r_1 = r_2 = q^4$, $F_0 = L^2$ (identified with the set $\mathcal{M}_4(K)$ of all $4 \times 4$ matrices with entries in $K$) and $F_2 = K^2$, $F_2 = K^8$ identified with $K^4 \times K^4$.

To each matrix $A \in \mathcal{M}_4(K)$, one can associate the partition of $K^8$ given by all four-dimensional affine subspaces of $K^8$ with equations $y = Ax + b$ where $b$ ranges over $K^4$. Each of these subspaces has size $q^4$. But two subspaces of equations $y = A'x + b'$ and $y = A''x + b''$ intersect in at most $q^3$ points (a three dimensional affine subspace) when $A' \neq A''$. Hence these partitions provide a $(q^4, q^4)$-adic $1/q$-brick.

Second example

We set $r_1 = r_2 = q$, $F_0 = L^2$ (identified with $K^4$) and $F_2 = K^2$.

To each quadruple $(a, b, c, d) \in K^4$, one can associate the partition of $K^2$ given by the $q$ graphs of equations $y = ax^4 + bx^3 + cx^2 + dx + e$ where $e$ ranges over $K$. Each of these graphs has size $q$. But two graphs with different $(a, b, c, d) \in K^4$ intersect in at most 4 points. Hence, if $p \geq 5$ these partitions provide a $(q, q)$-adic $4/q$-brick.

Gluing bricks together

In both examples above, the family of partitions provides bricks which can be glued as follows. Let $q$ be any power of a prime number. For each $n \leq 0$, call $K_n$ the field with $q^n = q^{2|n|}$ elements. Set

$$\forall n \leq 0, \quad F_{2n} = K_n^8, \quad r_{2n-1} = r_{2n} = q^n, \quad \alpha_n = 1/q_n \quad \text{and} \quad F_{2n-1} = F_{2n-2} \times [1, r_{2n-1}]$$

or

$$\forall n \leq 0, \quad F_{2n} = K_n^2, \quad r_{2n-1} = r_{2n} = q^n, \quad \alpha_n = 4/q_n \quad \text{and} \quad F_{2n-1} = F_{2n-2} \times [1, r_{2n-1}].$$

Start with a sequence of independent random variables $(Z_{2n})_{n \leq 0}$. For each $n \leq 0$, consider the partitions of $F_{2n}$ provided by the first or the second example and define $Z_{2n-1}$ from $Z_{2n-2}$ and $Z_{2n}$ as in lemma 17. By construction, $(Z_{2n}, Z_{2n-1}, Z_{2n})$ is an $(r_{2n-1}, r_{2n})$-adic $\alpha_n$-brick.

The next theorem shows that the process $(Z_n)_{n \leq 0}$ thus defined provides an example which proves the existence stated in theorem B.

2.8 Proof of theorem B

Theorem B directly follows from the construction above and from the theorem below.

**Theorem D.** Let $(\alpha_n)_{n \leq 0}$ be a sequence of reals in $]0, 1[$ such that the series $\sum_n \alpha_n$ converges. Let $(Z_n)_{n \leq 0}$ be any sequence of random variables taking values in some finite sets $(F_n)_{n \leq 0}$ of size $\geq 2$. Assume that
Then

- The random variables \((Z_{2n})_{n \leq 0}\) are independent;
- for each \(n \leq 0\), \((Z_{2n-2}, Z_{2n-1}, Z_{2n})\) is an \((r_{2n-1}, r_{2n})\)-adic \(\alpha_n\)-brick.

In particular, the filtration \((\mathcal{F}_{2n-1}^Z)_{n \leq 0}\) is at the threshold of standardness.

Proof of theorem D. We now prove the statements.

**Proof that \((Z_n)_{n \leq 0}\) is a Markov process and generates a \((r_n)\)-adic filtration**

First, note that the filtration \((\mathcal{F}_{2n}^Z)_{n \leq 0}\) is generated by the independent random variables \((Z_{2n})_{n \leq 0}\) since for every \(n \leq 0\), \(Z_{2n-1}\) is a deterministic function of \((Z_{2n-2}, Z_{2n})\).

Hence, for every \(n \leq 0\),

\[
\mathcal{F}_{2n-2}^Z = \sigma(Z_{2n-2}) \lor \mathcal{F}_{2n-4}^Z.
\]

Moreover, since \(Z_{2n-2}\) is a deterministic function of \(Z_{2n-1}\),

\[
\mathcal{F}_{2n-1}^Z = \sigma(Z_{2n-1}) \lor \mathcal{F}_{2n-2}^Z = \sigma(Z_{2n-1}) \lor \mathcal{F}_{2n-4}^Z.
\]

By independence of \((Z_{2n-2}, Z_{2n-1}, Z_{2n})\) and \(\mathcal{F}_{2n-4}^Z\), we get

\[
\mathcal{L}(Z_{2n-1}|\mathcal{F}_{2n-2}^Z) = \mathcal{L}(Z_{2n-1}|\sigma(Z_{2n-2})),
\]

\[
\mathcal{L}(Z_{2n}|\mathcal{F}_{2n-1}^Z) = \mathcal{L}(Z_{2n}|\sigma(Z_{2n-1})).
\]

The Markov property follows. But for every \(n \leq 0\), \((Z_{2n-2}, Z_{2n-1}, Z_{2n})\) is an \((r_{2n-1}, r_{2n})\)-adic \(\alpha_n\)-brick. The \((r_n)\)-adic character of \(\mathcal{F}_{2n}^Z\) follows.

**Proof that \((\mathcal{F}_{2n}^Z)_{n \in D}\) is not standard when \(D\) contains all but finitely many odd negative integers**

First, we show that \((\mathcal{F}_{2n}^Z)_{n \leq 0}\) is not standard. To do this, we check that the random variable \(Z_{-1}\) does not satisfy the \(I\)-cosiness criterion. Note that \((\mathcal{F}_{2n}^Z)_{n \leq 0}\) is the natural filtration of \((Z_{2n-1})_{n \leq 0}\) only since for every \(n \leq 0\), \(Z_{2n-2}\) is some deterministic function \(f_n\) of \(Z_{2n-1}\).

Let \((Z'_{2n-1})_{n \leq 0}\) and \((Z''_{2n-1})_{n \leq 0}\) be two copies of the process \((Z_{2n-1})_{n \leq 0}\), defined on some probability space \((\Omega, \mathcal{A}, \mathbb{P})\). Set \(Z'_{2n-2} = f_n(Z'_{2n-1})\) and \(Z''_{2n-2} = f_n(Z''_{2n-1})\) for every \(n \leq 0\). Then \((Z'_{n})_{n \leq 0}\) and \((Z''_{n})_{n \leq 0}\) are copies of the process \((Z_{n})_{n \leq 0}\). Moreover, \((\mathcal{F}_{2n-1}^Z)_{n \leq 0}\) and \((\mathcal{F}_{2n-1}^Z)_{n \leq 0}\) are the natural filtrations of \((Z'_{2n-1})_{n \leq 0}\) and \((Z''_{2n-1})_{n \leq 0}\).

Assume that these filtrations are immersed in some filtration \((\mathcal{G}_{2n-1})_{n \leq 0}\). Then, for every \(n \leq -1\),

\[
\mathcal{L}(Z'_{2n+1}|\mathcal{G}_{2n-1}) = \mathcal{L}(Z'_{2n+1}|\mathcal{F}_{2n-1}^Z) = \mathcal{L}(Z'_{2n+1}|\sigma(Z'_{2n-1})),
\]

and since \(Z'_{2n}\) is a deterministic function of \(Z'_{2n+1}\),

\[
\mathcal{L}(Z'_{2n}|\mathcal{G}_{2n-1}) = \mathcal{L}(Z'_{2n}|\sigma(Z'_{2n-1})).
\]

The same holds with the process \(Z''\).
For any distinct values $z', z''$ in $F_{2n-1}$, one has on the event $[Z'_{2n-1} = z' ; Z''_{2n-1} = z'']$,

$$
P[Z'_{2n} = Z''_{2n} | G_{2n-1}] = \sum_{z \in F_{2n}} P[Z'_{2n} = z ; Z''_{2n} = z | G_{2n-1}] \leq \sum_{z \in F_{2n}} P[Z'_{2n} = z | G_{2n-1}] \land P[Z''_{2n} = z | G_{2n-1}] = \sum_{z \in F_{2n}} P[Z'_{2n} = z | Z'_{2n-1} = z'] \land P[Z''_{2n} = z | Z''_{2n-1} = z''] = \sum_{z \in F_{2n}} P[Z_{2n} = z | Z_{2n-1} = z'] \land P[Z_{2n} = z | Z_{2n-1} = z''] \leq \alpha_n.
$$

Hence, since $[Z'_{2n+1} = Z''_{2n+1}] \subset [Z'_{2n} = Z''_{2n}]$,

$$
\mathbb{P}[Z'_{2n+1} = Z''_{2n+1} | G_{2n-1}] \leq \mathbb{P}[Z'_{2n} = Z''_{2n} | G_{2n-1}] \leq \alpha_n \mathbf{1}_{[Z'_{2n-1} \neq Z''_{2n-1}]} + \mathbf{1}_{[Z'_{2n-1} = Z''_{2n-1}]}.
$$

Taking the complements, one gets

$$
\mathbb{P}[Z'_{2n+1} \neq Z''_{2n+1} | G_{2n-1}] \geq (1 - \alpha_n) \mathbf{1}_{[Z'_{2n-1} \neq Z''_{2n-1}]}.
$$

A simple recursion yields

$$
P[Z'_{-1} \neq Z''_{-1} | G_{2n-1}] \geq \prod_{n \leq k \leq -1} (1 - \alpha_k) \mathbf{1}_{[Z'_{2n-1} \neq Z''_{2n-1}]}.
$$

Taking the expectations, one gets

$$
P[Z'_{-1} \neq Z''_{-1}] \geq \prod_{n \leq k \leq -1} (1 - \alpha_k) P[Z'_{2n-1} \neq Z''_{2n-1}].
$$

Assume now that for some $N > -\infty$, the $\sigma$-fields $\mathcal{F}_{2N-1}'$ and $\mathcal{F}_{2N-1}''$ are independent. Then for every $n \leq N$,

$$
P[Z'_{2n-1} \neq Z''_{2n-1}] = 1 - \frac{1}{|F_{2n-1}|} \geq \frac{1}{2},
$$

since $Z'_{2n-1}$ and $Z''_{2n-1}$ are independent and uniform on $F_{2n-1}$. Going to the limit yields

$$
P[Z'_{-1} \neq Z''_{-1}] \geq \frac{1}{2} \prod_{k \leq -1} (1 - \alpha_k) > 0,
$$

which shows that $Z_{-1}$ does not satisfy the I-cosiness criterion.

Thus $(\mathcal{F}_{2n-1}')_{n \leq 0}$ is not standard. Thus, if $D$ is any subset of $\mathbb{Z}_-$ which contains all odd negative integers, the filtration $(\mathcal{F}_{2n}')$ is not standard (since standardness is preserved by extraction). This conclusion still holds when $D$ contains all but finitely many odd negative integers (since standardness is an asymptotic property).

**Proof that $(\mathcal{F}_{2n}')_{n \in D}$ is standard when $D$ skips infinitely many odd negative integers**

Since standardness is preserved by extraction, one only needs to consider the case where $D$ contains all even non-positive numbers. In this case, the filtration $(\mathcal{F}_{2n}')_{n \in D}$ is
generated by $(Z_n)_{n \in D}$ only. Indeed, if $n$ is any integer in $\mathbb{Z}_- \setminus D$, then $n$ is odd, hence $n - 1 \in D$, $n + 1 \in D$ and $Z_n$ is a function of $(Z_{n-1}, Z_{n+1})$.

For each $n \leq 0$, the conditional law $\mathcal{L}(Z_n|\mathcal{F}^Z_{n-1}) = \mathcal{L}(Z_n|Z_{n-1})$ is (almost surely) uniform on some random subset of $F_n$ with $r_n$ elements. By fixing a total order on the set $F_n$, one can construct an uniform random variable uniform $U_n$ on $[1, r_n]$, independent of $\mathcal{F}_{n-1}^Z$, such that $Z_n$ is a function of $Z_{n-1}$ and $U_n$. Set $Y_n = Z_n$ if $n - 1 \in D$ (which may happen only for even $n$) and $Y_n = U_n$ otherwise. Then $Y_n$ is $\mathcal{F}_{n}^Z$-measurable. This shows that $\mathcal{F}_n^Y \subset \mathcal{F}_n^Z$ for every $n \in D$.

Let us prove the reverse inclusion. Fix $n \in D$, and call $m \leq n$ the integer such that $m - 1 \notin D$ but $k \in D$ for all $k \in [m, n]$. Then $Z_n$ is $\mathcal{F}_n^Y$-measurable as a function of $Y_m = Z_m, Y_{m+1} = U_{m+1}, \ldots, Y_n = U_n$.

Last, for every $n \in D$, $Y_n$ is independent of $\mathcal{F}_{n-1}^Z$ if $n - 1 \in D$ and $Y_n$ is independent of $\mathcal{F}_{n-2}^Z$ otherwise. This shows the independence of the random variables $(Y_n)_{n \in D}$. Hence the filtration $(\mathcal{F}_n^Z)_{n \in D}$ is of product type, which completes the proof.

3 Annexe: some basic facts on standardness

We summarize here the main definitions and results used in this paper. A complete exposition can be found in [2]

Recall that we work with filtrations indexed by the non-positive integers on a probability space $(\Omega, \mathcal{A}, \mathbb{P})$, and that all the sub-$\sigma$-fields of $\mathcal{A}$ that we consider here are assumed to be complete and essentially separable with respect to $\mathbb{P}$.

Most of the time, the probability measure $\mathbb{P}$ is not explicitly mentioned when we deal with filtrations. Yet, it actually plays an important role and the true object of study are filtered probability spaces $(\Omega, \mathcal{A}, \mathbb{P}, (\mathcal{F}_n)_{n \leq 0})$.

3.1 Isomorphisms of filtered probability spaces

The definition of isomorphism is not as simple as one could expect.

Let $\mathcal{F} = (\mathcal{F}_n)_{n \leq 0}$ and $\mathcal{F}′ = (\mathcal{F}_n′)_{n \leq 0}$ be filtrations on $(\Omega, \mathcal{A}, \mathbb{P})$ and $(\Omega′, \mathcal{A}, \mathbb{P})$.

**Definition 18.** An isomorphism of filtered probability spaces from $(\Omega, \mathcal{A}, \mathbb{P}, \mathcal{F})$ into $(\Omega′, \mathcal{A}′, \mathbb{P}, \mathcal{F}′)$ is a bijective (linear) application from the space $L^0(\Omega, \mathcal{F}, \mathbb{P})$ of the real random variables on $(\Omega, \mathcal{F}, \mathbb{P})$ into $L^0(\Omega′, \mathcal{F}_\infty, \mathbb{P})$ which preserves the laws of the random variables, commutes with Borelian applications, and sends $\mathcal{F}$ on $\mathcal{F}′$.

By definition, saying that an isomorphism $\Psi$ sends $\mathcal{F}$ on $\mathcal{F}′$ means that for every $n \leq 0$, the random variables $\Psi(X)$ for $X \in L^0(\Omega, \mathcal{F}_n, \mathbb{P})$ generate $\mathcal{F}_n'$. Saying that $\Psi$ commutes with Borelian applications means that for every sequence $(X_n)_{n \geq 1}$ of real random variables on $(\Omega, \mathcal{A}, \mathbb{P})$, and every Borelian application $F : \mathbb{R}^\infty \to \mathbb{R}$,

$$\Psi(F \circ (X_n)_{n \geq 1}) = F \circ (\Psi(X_n))_{n \geq 1}.$$ 

In particular, this equality holds when $F$ is given by $F((x_n)_{n \geq 1}) = \alpha_1 x_1 + \alpha_2 x_2$ with $(\alpha_1, \alpha_2) \in \mathbb{R}^2$, which shows that $\Psi$ is linear.
Of course, any bimeasurable application \( \psi \) from \( (\Omega, \mathcal{F}_\infty) \) to \( (\Omega', \mathcal{F}'_\infty) \) which sends \( P \) on \( P' \) induces an isomorphism \( \Psi \) from \( (\Omega, \mathcal{A}, P, \mathcal{F}) \) into \( (\Omega', \mathcal{A}', P', \mathcal{F}') \), defined by \( \Psi(X) = X \circ \phi^{-1} \). Yet, the converse is not true: an isomorphism of filtered spaces from \( (\Omega, \mathcal{F}_\infty) \) to \( (\Omega', \mathcal{F}'_\infty) \) is not necessarily associated to some bimeasurable application from \( \Omega \) to \( \Omega' \) which sends \( P \) on \( P' \).

As a matter of fact, the most interesting objects associated to a probability space \( (\Omega, \mathcal{A}, P) \) are the random variables and not the elements of \( \Omega \). Note that for any sequence \( (X_n)_{n \leq 0} \) of random variables defined on \( (\Omega, \mathcal{A}, P) \), the filtrations which are isomorphic to the natural filtration of \( (X_n)_{n \leq 0} \) are exactly the filtrations of the copies of \( (X_n)_{n \leq 0} \) on arbitrary probability spaces.

### 3.2 Immersion of filtrations

Let \( \mathcal{F} = (\mathcal{F}_n)_{n \leq 0} \) and \( \mathcal{G} = (\mathcal{G}_n)_{n \leq 0} \) be filtrations on \( (\Omega, \mathcal{A}, P) \).

**Definition 19.** One says that \( \mathcal{F} \) is immersed into \( \mathcal{G} \), if, for every \( n \leq 0 \), \( \mathcal{F}_n \subset \mathcal{G}_n \) and \( \mathcal{F}_n \) is independent of \( \mathcal{G}_{n-1} \) conditionally on \( \mathcal{F}_{n-1} \). Equivalently, \( \mathcal{F} \) is immersed into \( \mathcal{G} \) if and only if every martingale in \( \mathcal{F} \) is still a martingale in \( \mathcal{G} \).

Immersion is stronger than mere inclusion. If \( \mathcal{F} \) is immersed into \( \mathcal{G} \), the additional information contained in \( \mathcal{G} \) cannot give information on \( \mathcal{F} \) in advance: intuitively, the independence of \( \mathcal{F}_n \) and \( \mathcal{G}_{n-1} \) conditionally on \( \mathcal{F}_{n-1} \) means that \( \mathcal{G}_{n-1} \) gives no more information on \( \mathcal{F}_n \) than \( \mathcal{F}_{n-1} \) does.

The notion of immersion is implicitly present in many usual situations. For instance, when one considers a Markov process \( X \) in some filtration \( \mathcal{G} \), it means that the natural filtration of \( X \) is immersed in \( \mathcal{G} \).

### 3.3 Immerisibility and standardness

The notion of immersion can be weakened to provide a notion invariant by isomorphism.

**Definition 20.** Let \( \mathcal{F} = (\mathcal{F}_n)_{n \leq 0} \) and \( \mathcal{G}' = (\mathcal{G}'_n)_{n \leq 0} \) be filtrations on \( (\Omega, \mathcal{A}, P) \) and \( (\Omega', \mathcal{A}', P') \). One says that \( \mathcal{F} \) is immersible into \( \mathcal{G}' \) if there exists a filtration \( \mathcal{F}' \) on \( (\Omega', \mathcal{A}', P') \), isomorphic to \( \mathcal{F} \), such that \( \mathcal{F}' \) is immersed into \( \mathcal{G}' \).

We can now define the standardness of filtrations.

**Definition 21.** A filtration is standard if it is immersible into a product-type filtration.

Because of Kolmogorov’s 0-1 law, any filtration must have a trivial tail \( \sigma \)-field in order to be standard, but this necessary condition is not sufficient. In [10], Vershik established two different characterisations of standardness in the context of decreasing sequences of measurable partitions, which were extended and reformulated into a probabilistic language and called Vershik’s “first level” and “second level” criteria by Émery and Schachermayer [2]. Émery and Schachermayer also introduced a new standardness criterion, namely the I-cosiness criterion.

### 3.4 I-cosiness criterion

Let \( \mathcal{F} = (\mathcal{F}_n)_{n \leq 0} \) be a filtration on \( (\Omega, \mathcal{A}, P) \).
Definition 22. Let $R$ be any $\mathcal{F}_0$-measurable real random variable $R$. One says that $R$ satisfies I-cosiness criterion for $(\mathcal{F}_n)_{n \leq 0}$ (to abbreviate, we say that $I(R)$ holds) if for any positive real number $\delta$, there exists a probability space $(\Omega, \mathcal{A}, P)$ supplied with two filtrations $\mathcal{F}'$ and $\mathcal{F}''$ such that:

- the filtrations $\mathcal{F}'$ and $\mathcal{F}''$ are isomorphic to the filtration $\mathcal{F}$;
- the filtrations $\mathcal{F}'$ and $\mathcal{F}''$ are immersed into $\mathcal{F}' \lor \mathcal{F}''$;
- there exists an integer $n_0 < 0$ such that the $\sigma$-fields $\mathcal{F}'_{n_0}$ and $\mathcal{F}''_{n_0}$ are independent;
- the copies $R'$ and $R''$ of $R$ given by the isomorphisms of the first condition are such that $P[|R' - R''| \geq \delta] \leq \delta$.

One says that $\mathcal{F}$ is I-cosy when $I(R)$ holds for every $R \in L^0(\Omega, \mathcal{F}_0, P)$.

The definition of I-cosiness was implicitly used by Smorodinsky in [8] to prove that the dyadic split-words filtration is not standard (although Smorodinsky uses a different terminology). The I stands for independence, to distinguish I-cosiness from other variants of cosiness.

Intuitively, the conditions defining $I(R)$ mean that one can couple two copies of $\mathcal{F}$ in a non-anticipative way so that old enough independent initial conditions have weak influence on the final value of $R$.

Laurent noticed that if $I(R)$ holds, then $I(\phi(R))$ holds for every Borel function $\phi$ from $\mathbb{R}$ to $\mathbb{R}$. Hence, to prove that $\mathcal{F}$ is I-cosy, it is sufficient to check that $I(R)$ for one real random variable generating $\mathcal{F}_0$.

It is also sufficient and sometimes handful to check $I(R)$ for all random variables with values in an arbitrary finite set, with the discrete distance $1_{[R' \neq R'']} \text{ replacing } |R' - R''|$ in the definition of $I(R)$.

I-cosiness provides a standardness criterion.

Theorem E. (Émery and Schachermayer [2]) $\mathcal{F}$ is standard if and only if $\mathcal{F}$ is I-cosy.
