(Received: 15 April 2017; accepted: 02 June 2017)

A field experiment was carried out at Agronomy Farm, B. A. College of Agriculture, Anand Agricultural University, Anand, Gujarat during the summer season of the year 2015 to study the effect of time of sowing, row spacing and variety on summer cluster bean under middle Gujarat conditions, in loamy sand soil. Eighteen treatment combinations comprised of three dates of sowing viz., D₁; (21st January); D₂; (1st February) and D₃; (11th February) as main plot treatments and combination of three different row spacing viz., S₁; 30 cm; S₂; 45 cm; and S₃; 60 cm along with two varieties V₁ (GG 1) and V₂ (GG 2) as sub plot treatments, were laid out in Split Plot Design with three replications. Results revealed that treatment combination D₃S₁V₂ (sowing on 11th February with 30 cm row spacing with variety GG 2) recorded significantly higher seed yield (1476 kg ha⁻¹) which was found at par with treatment combination D₂S₃V₂ (sowing on 1st February with 60 cm row spacing with variety GG 2). However, maximum net realization (Rs.50667 ha⁻¹) and BCR (4.53) were obtained under treatment combination D₂S₃V₂, followed by D₃S₁V₂ with net realization of Rs.48511 ha⁻¹ and BCR of 4.24.

Keywords: Time of sowing, row spacing, variety, cluster bean.
1) and Gujarat Guar 2 (GG 2) have been released by G.A.U., S.K. Nagar, which have been found suitable for cultivation during summer season in north Gujarat conditions. But the performance of cluster bean varieties at varied time of sowing and row spacing have not been evaluated for middle Gujarat conditions in summer season. Therefore, this experiment was conducted.

**MATERIALS AND METHOD**

A field experiment was carried out at Agronomy Farm, B. A. College of Agriculture, Anand Agricultural University, Anand, Gujarat during the summer season of the year 2015 to study the effect of time of sowing, row spacing and variety on summer cluster bean under middle Gujarat conditions, in loamy sand soil, low in organic carbon (0.35%), medium in available phosphorous (43.28 kg P$_2$O$_5$ ha$^{-1}$) and high in available potash (388.17 kg K$_2$O ha$^{-1}$). Eighteen treatment combinations comprised of three dates of sowing viz., D$_1$: (21st January); D$_2$: (1st February) and D$_3$: (11th February) as main plot treatments and combination of three different row spacing viz., S$_1$: 30 cm; S$_2$: 45 cm; and S$_3$: 60 cm along with two varieties V$_1$ (GG 1) and V$_2$ (GG 2) as sub plot treatments, were laid out in Split Plot Design with three replications.

**RESULTS AND DISCUSSION**

**Effect of time of sowing**

A perusal of data presented in table-1 revealed that sowing on 1st February (D$_2$) being at par with sowing on 11th February (D$_3$) gave significantly higher plant height at 30 (32.31 cm), 60 DAS (56.47 cm) and at harvest (82.97 cm) and for test weight (38.90 g) of cluster bean over sowing on 21st January (D$_1$). Conversely, crop sown on 11th February (D$_3$) produced significantly the highest branches plant$^{-1}$ (6.01), pods plant$^{-1}$ (43.92), seeds pod$^{-1}$ (7.96) and pod length (9.11 cm) over early sowing on 1st February (D$_2$) and 21st January (D$_1$). Better growth of plant in terms of plant height under late sowing on 1st February (D$_2$) and 11th February (D$_3$) reflected into better development of yield attributes. Moreover, congenial climatic conditions especially at reproductive phase also played vital role in development of yield attributes due to positive sink to source ratio wherein assimilates translocation to reproductive components. These

findings are substantiated with those reported by Patel et al., (2004) and Vishal et al., (2014).

Similar trend was observed for seed and stalk yield. The impact of different time of sowing on seed and stalk yield of cluster bean reported in table 2 indicated that 1st February sowing (D1), being at par with 11th February sowing (D2) produced significantly higher seed (1027 kg ha⁻¹) as well as stalk (5043 kg ha⁻¹) yield which were 21.12 % and 27.87 % higher over 21st January sowing (D3), respectively. Higher seed and stalk yield under treatments D₂ (1st February) and D₁ (11th February) over D₃ (21st January) might be attributed to enhanced yield attributes in later sowing over early sowing under favorable weather conditions which might induced photosynthetic activity and translocation of assimilates which was reflected in augmentinggermination, plant height and ultimately had complimentary impact on number of branches plant⁻¹, pod development and seed formation (Kalyani, 2012).

Harvest index (Table 2) was found unchanged due to different time of sowing. However, maximum harvest index (19.56 %) was reported under sowing on 11th February (D₃).

Effect of row spacing

Results given in table-1 and table-2 revealed that significantly the highest plant height at 60 DAS (55.96 cm) and at harvest (82.04 cm) and stalk yield (4859 kg ha⁻¹) were obtained when crop sown at 30 cm spacing (S₁) over rest of the treatments. Nevertheless, crop sown at 60 cm spacing (S₃) being at par with 45 cm spacing (S₂) produced significantly higher pod length (8.24 cm) and seeds pod⁻¹ (7.13) over 30 cm spacing (S₁). Plant height at 30 DAS, branches plant⁻¹, pods plant⁻¹, test weight (g), seed yield (kg ha⁻¹) and harvest index (%) were found statistically at par due to different row spacing. Under wider spacing some of the yield components might have been increased on individual plant basis but would have been decreased on per unit area basis, while under narrow spacing though number of plants per unit area might have been increased, but the yield components might have been declined on individual basis and eventually the biological yield was reduced. A similar result was obtained by Machado et al., (2003).

Effect of variety

In the present experiment different varieties showed imperial impact on all the growth

| Treatments       | Seed yield (kg ha⁻¹) | Stalk yield (kg ha⁻¹) | Harvest index (%) |

Table 2. Effect of time of sowing, row spacing and variety on seed and stalk yield and harvest index of Cluster bean
parameters, yield attributing characters and yield (Table 1 and Table-2). Variety GG 2 (V₂) proved statistically superior over variety GG1 (V₁) in all the aspects barring periodical plant height and stalk yield. Significantly maximum branches plant⁻¹ (6.13), pods plant⁻¹ (40.89), pod length (9.28 cm), number of seeds pod⁻¹ (8.07), test weight (41.86 g), seed yield (1245 kg ha⁻¹) and harvest index (26.59 %) were recorded under variety GG 2 (V₂) over GG 1 (V₁). On the other hand, variety GG 1 (V₁) exhibited higher plant height at 30 DAS (34.38 cm), 60 DAS (60.12 cm) and at harvest (88.39 cm) and produced higher stalk yield (5392 kg ha⁻¹) over variety GG 2 (V₂). Variety GG 2 (V₂) produced 89 % higher seed yield over variety GG 1 (V₁). This can be attributed to higher biomass accumulation coupled with effective translocation and distribution of photosynthesis from source to sink (Patel et al., 2010).

**Interaction effect**

Interaction effect between D X V was found significant (Table 3(a)) for plant height at 30 DAS, pod length, seeds pod⁻¹, stalk yield and harvest index. Treatment combination Dᵥ₁V₁ (sowing on 11th February with GG 1) being at par with treatment combination Dᵥ₂V₁ (sowing on 1st January with GG 1) reported significantly higher plant height (37.17 cm) as well as stalk yield (5589 kg ha⁻¹). However, in case of pod length and number of seeds pod⁻¹, treatment combination Dᵥ₂V₂ (sowing on 11th February with GG 2) out right produced highest pod length (10.95 cm) and number of seeds pod⁻¹ (9.84). Significantly higher harvest index (28.96) was reported under treatment combination Dᵥ₁V₂ which remained at par with Dᵥ₂V₂.

Interaction between D X S (Table 3(b)) were found significant for seed yield as well as harvest index, wherein treatment combination Dₛ₁S₂ (sowing on 11th February at 30 cm row spacing) gave significantly higher seed yield (1085 kg ha⁻¹) and harvest index (22.05 %). Nevertheless, it remained at with Dₛ₁S₁ and Dₛ₁S₂ for seed yield and with Dₛ₂S₁ and Dₛ₂S₂ for harvest index.

Number of pod plant⁻¹, seed yield as well as harvest index were found significantly influenced due to interaction between S X V (Table 3 (c)) and treatment combination Sᵥ₃V₂ gave appreciably higher Number of pod plant⁻¹ (42.51), seed yield (1245 kg ha⁻¹) and harvest index (28.02 %).

The perusal of result given in table 3(d) revealed that treatment combination D\(_3\), S\(_1\), V\(_2\) (cluster bean variety GG 2 sown on 11\(^{th}\) February with 30 cm row spacing), being at par with D\(_2\), S\(_3\), V\(_2\) (cluster bean variety GG 2 sown on 1\(^{st}\) February with 60 cm row spacing) produced significantly higher seed yield (1476 kg ha\(^{-1}\)) over rest of the treatment combinations. This could be also attributed to higher biomass accumulation coupled with effective translocation and distribution of photosynthates from source to sink. The result was also supported by Sonani et al. (2016).

**Economics**

Data pertaining to economics (Table-4) clearly indicated that the highest net realization Rs. 50667 ha\(^{-1}\) and BCR (4.53) were obtained under treatment combination D\(_2\), S\(_3\), V\(_2\), i.e. cluster bean variety GG 2 sown on 1\(^{st}\) February with 60 cm

Selling Price: Seed – Rs. 40 kg⁻¹, Stalk – Rs. 1.5 kg⁻¹

row spacing; followed by treatment combination D₁S₁V₂ i.e. cluster bean variety GG 2 sown on 11th February with 30 cm row spacing, with net realization of Rs. 47511 ha⁻¹ and BCR of 4.24.

CONCLUSION

In light of the above results it can be concluded that summer cluster bean variety GG-2 should be sown on 1st February with wider row spacing of 60 cm for getting higher yield and monetary return. In case, sowing is delayed, variety GG-2 should be sown on 11th February at narrow spacing of 30 cm.
