Abstract

The common marmoset (Callithrix jacchus) is considered a novel experimental animal model of non-human primates. However, due to antibody unavailability, immunological and pathological studies have not been adequately conducted in various disease models of common marmoset. Quantitative real-time PCR (qPCR) is a powerful tool to examine gene expression levels. Recent reports have shown that selection of internal reference housekeeping genes are required for accurate normalization of gene expression. To develop a reliable qPCR method in common marmoset, we used geNorm applets to evaluate the expression stability of eight candidate reference genes (GAPDH, ACTB, rRNA, B2M, UBC, HPRT, SDHA and TBP) in various tissues from laboratory common marmosets. geNorm analysis showed that GAPDH, ACTB, SDHA and TBP were generally ranked high in stability followed by UBC. In contrast, HPRT, rRNA and B2M exhibited lower expression stability than other genes in most tissues analyzed. Furthermore, by using the improved qPCR with selected reference genes, we analyzed the expression levels of CD antigens (CD3, CD4, CD8α and CD20) and cytokines (IL-1β, IL-2, IL-4, IL-5, IL-6, IL-10, IL-12(β), IL-13, IFN-γ and TNF-α) in peripheral blood leukocytes and compared them between common marmosets and humans. The expression levels of CD4 and IL-4 were lower in common marmosets than in humans whereas those of IL-10, IL-12(β) and IFN-γ were higher in the common marmoset. The ratio of Th1-related gene expression level to that of Th2-related genes was inverted in common marmosets. We confirmed the inverted ratio of CD4 to CD8 in common marmosets by flow cytometric analysis. Therefore, the difference in Th1/Th2 balance between common marmosets and humans may affect host defense and/or disease susceptibility, which should be carefully considered when using common marmoset as an experimental model for biomedical research.

Introduction

The common marmoset (Callithrix jacchus) is a New World monkey and is considered potentially useful as an experimental animal model in research fields such as drug toxicity [1,2], neuroscience [3,4], autoimmune diseases [5,6] and infectious diseases [7,8], because of its size, availability and high genetic similarity with humans [9,10]. Compared with mice, common marmosets are more useful as an in vivo model to study immune function [11]. However, essential tools and gene information for conducting studies using common marmosets are in short supply or unavailable. For example, monoclonal antibodies specific for common marmosets have been only partially established. Although DNA microarray research for common marmoset brain has been reported [12], sufficient studies have not been performed in other research fields.

Quantitative real-time polymerase chain reaction (qPCR) is the dominant quantitative technique for gene expression analysis due to its broad dynamic range, accuracy, sensitivity, specificity and...
speed [13]. Thus, qPCR is very useful for investigating physiological and pathological status from a small amount of sample. Normalization to reference genes such as housekeeping genes is usually required for qPCR analysis. However, expression levels of reference genes may vary between tissues, cell types and experimental conditions. Therefore, the validation of suitable reference genes in each experiment is critical for the accurate evaluation of qPCR data. Recently, a set of guidelines for evaluating qPCR experiments was developed [14] and a strict method for the selection of reference genes suitable for normalization was proposed [13]. A freely available program, geNorm applet (http://medgen.ugent.be/~jdesomp/genorm/), can determine gene stability ranking and the number of reference genes required for normalization in a given panel of samples [15].

To develop an accurate and reliable qPCR method for common marmosets, we examined the expression stabilities of candidate reference genes in various tissues of laboratory common marmosets using geNorm applet. Then, we compared expression levels of immune-related genes in peripheral blood leukocytes between common marmosets and humans. To the best of our knowledge, this is the first such study for the selection of reference genes in common marmosets. The present data will contribute to future studies of gene expression analysis by qPCR for common marmosets.

Materials and Methods

Ethics statement

The study was conducted in accordance with the Act on Welfare and Management of Animals of Japanese government. All animals were housed, cared for, and used according to the principles set forth in the Guide for the Care and Use of Laboratory Animals: Eighth Edition (National Research Council, 2011). All experiments using common marmosets were approved by the committee for animal experiments at the National Institute of Infectious Diseases (Approval Number: 610,007). For humans, whole blood was obtained from eight healthy volunteers (mean age ± sd: 35.7±13.0 years old) after obtaining written informed consent. This study and the consent procedure were approved by the ethics committee of Tokai University School of Medicine (Approval Number: 101-22).

Animals

Eight common marmosets (1.58±0.29 years old) were obtained from CLEA Japan, Inc. (Tokyo, Japan) and maintained in specific pathogen-free conditions at the National Institute of Infectious Diseases (Tokyo, Japan). Common marmosets were housed solely or in pairs in a single cage 39 cm (W)×55 (D)×70 (H) in size on 12:12 h light/dark cycles. Room temperature and humidity were maintained at 26–27 °C and 40–50%, respectively. Filtered drinking water was delivered by an automatic watering system and total 40–50 g/individual of common marmoset chow (CMS-1M, CLEA Japan) were given in a couple of times per day. Dietary supplements (sponge cakes, eggs, banana pudding, honeys, vitamin C and D3) were also given to improve their health status. Machinery noise and dogs’ barks were avoided to reduce stress. After sacrifice, various tissues removed, and whole blood was obtained from all eight common marmosets.

RNA isolation

Heparinized venous blood samples from common marmosets were obtained before sacrifice and incubated in erythrocyte lysis buffer (155 mM NH₄Cl, 10 mM KHCO₃, and 0.1 mM EDTA). Following incubation on ice for 5 min, cells were centrifuged at 300×g for 10 min at 4 °C and washed with lysis buffer and then PBS. Leukocytes were lysed with QIAzol® Lysis Reagent (Qiagen, Hilden, Germany) and total RNA was extracted using an RNeasy® Plus Universal Mini Kit (Qiagen) according to the manufacturer’s instructions. Tissue samples (spleen, mesenteric lymph node, jejunum, ileum, descending colon, cerebrum, cerebellum, brainstem, heart, lung, liver and kidney) were excised from each animal and immediately submerged in RNAlater® RNA Stabilization Reagent (Qiagen). Then total RNA was extracted using RNeasy® Plus Universal Mini Kit (Qiagen). RNA concentration and integrity were assessed using the Agilent RNA 6,000 Nano Kit (Agilent Technologies, Inc., CA, USA) in an Agilent 2100 Bioanalyzer. All RNA samples were confirmed to have no degradation and were of optimal quality for downstream qPCR applications.

Candidate reference genes

Based on a literature search, eight commonly used candidate internal control genes were selected for analysis: GAPDH (glyceraldehyde-3-phosphate dehydrogenase), ACTB (actin, beta), 18S rRNA (18S ribosomal RNA), B2M (beta-2-microglobulin), UBC (ubiquitin C), HPRT (hypoxanthine phosphoribosyltransferase 1), SDHA (succinate dehydrogenase complex, subunit A) and TBP (TATA-box binding protein). All genes chosen have independent cellular functions and are not thought to be co-regulated. The sequences of primers specific for each reference gene are shown in Table 1.

Quantitative real-time PCR

First-strand cDNA was synthesized using PrimeScript® RT reagent Kit (Takara Bio, Otsu, Japan) with attached random hexamers and oligo(dT) primers. Reactions were incubated at 37 °C for 15 min followed by 85 °C for 5 sec according to the manufacturer’s instructions. Then each cDNA sample was diluted with RNase/DNase-free water to 25 ng/μL. The expression level of each gene was analyzed by qPCR using the Bio-Rad CFX96 system (Bio-Rad Laboratories, Inc., Hercules, CA, USA). PCR reactions consisted of 5 μL of SsoFastTM EvaGreen® Supermix (Bio-Rad), 3.5 μL of RNase/DNase-free water, 0.5 μL of 5 μM primer mix, 1 μL of cDNA in a total volume of 10 μL. The primer sequences are shown in Tables 1 and 2. Cycling conditions were as follows: 30 sec at 95 °C followed by 45 rounds of 95 °C for 1 sec and 60 °C for 5 sec. Melting curve analysis to determine the dissociation of PCR products was performed between 65 °C and 95 °C. Data were expressed as mean values of experiments performed in triplicate. Seven points of a 10-fold serial dilution of standard DNA was used for absolute quantification. Standard DNA was generated by cloning PCR products into pGEM-T Easy Vector (Promega, WI, USA). Sequences of the cloned plasmid were confirmed by DNA sequencing using the CEQ8800 Genetic Analysis System (Beckman Coulter). Quality and concentration of the plasmid DNA were validated using Agilent DNA 7,500 Kit in an Agilent 2100 Bioanalyzer.
Analysis of gene expression stability

The expression stability of selected reference genes was evaluated using a publicly available program, geNorm applet [15]. geNorm calculates the stability of tested reference genes according to the similarity of their expression profiles by pairwise comparison and M value, where the gene with the highest value is the least stable one. It is possible to perform sequential elimination of the least stable gene in any given experimental group, thus resulting in the exclusion of all but the two most stable genes in each case.

Flow cytometry

Heparinized peripheral blood was collected from common marmosets and centrifuged in Lymphocepal (IBL Co. Takasaki, Japan) at 2,000 rpm for 30 min. Mononuclear cells were collected and re-suspended in RPMI1640 medium containing 10% fetal calf serum. Cells were stained with anti-common marmoset CD8 antibody (Mar8–10) [16] for 15 min at 4°C and washed with 1% (w/v) bovine serum albumin-containing PBS. Subsequently, cells were stained with phycoerythrin-labeled secondary antibody, peridinin chlorophyll protein cyanin5.5 (PerCPCy5.5)-conjugated anti-human CD3 (SP34-2) and Alexa488-conjugated anti-common marmoset CD4 (Mar4-33) antibodies [16]. Peripheral blood from healthy human volunteers was collected and mononuclear cells isolated by Ficoll-Paque (GE Healthcare Biosciences, Uppsala, Sweden) gradient centrifugation. The monoclonal antibodies used for cell staining were as follows: PerCPCy5.5-conjugated anti-human CD3 (SP34-2), allophycocyanin-conjugated anti-human CD4 (SK3), fluorescein isothiocyanate-conjugated anti-human CD8 (HIT8a) (BD PharMingen). Cells were analyzed by FACS Calibur (Becton Dickinson, Franklin Lakes, NJ, USA).

Statistical analysis

Student’s t-test was used for statistical analysis to assess significant differences in qPCR assays. A P value<0.05 was considered to be statistically significant.

Results

The expression levels of candidate reference genes in tissues

Eight housekeeping genes were chosen as reference genes: GAPDH, ACTB, rRNA, B2M, UBC, HPRT, SDHA and TBP. We determined the transcription levels of these eight genes in 13 tissues (leukocyte, spleen, lymph node, jejunum, ileum, colon, cerebrum, cerebellum, brainstem, heart, lung, liver and kidney) from four individual common marmosets by qPCR. The sequences of primers specific for each reference gene are shown in Table 1. The expression level of each gene in each tissue is shown as the copy number per mg of purified total RNA (Figure 1).

The most abundant gene was rRNA while the rarest gene was UBC and the difference in expression level between the two genes was more than 100,000-fold. For several genes, the expression levels were highly different among tissues. For example, B2M expression in heart and brain segments (cerebrum, cerebellum and brainstem) was markedly lower than in other tissues. HPRT expression also showed a large variability among tissues. In addition, the expression levels of rRNA, B2M and HPRT varied among individuals; the mean values of standard deviation were 0.224, 0.235 and 0.303, respectively, while those of the other genes were below 0.2.

A variety of gene expression stabilities among tissues

To evaluate the expression stability of selected reference genes, we used a publicly available program, geNorm applets. geNorm provides a ranking of tested genes based on the reference gene stability measure M, which is defined as the average pairwise variation of a particular gene compared with all other control genes. Thus, genes with higher M values have greater variations of expression. In addition, assessment of the pairwise variations (Vn/n + 1) between each combination of sequential normalization factors allows identification of the optimal number of reference genes. In the original publication describing geNorm [15], a threshold of 0.15 for pairwise variation was established, below which the inclusion of additional reference genes was not necessary.

geNorm analysis produced line plots indicating the mean expression stability M of the remaining candidate reference genes in each round of the analysis (Figure 2A and 2B), the pairwise variation V (Figure 2C) and ranking of the candidate reference genes from the least stable to the two most stable genes (Figure 3). The stability score M indicated that gene expression in spleen, jejunum and cerebellum were relatively less stable than other tissues (Figure 2A and B). However, all tissues tested exhibited high stabilities, as M values were less than 1.5, which was the default limit even when all eight genes were analyzed. According to pairwise variation V (Figure 2C), the two most stable genes were sufficient for a stable and valid reference for each tissue analyzed by qPCR because V2/3 values were less than 0.15 in all tissues. Jejunum was the most variable tissue with a V2/3 value of 0.139. Figure 3 shows ranking of gene expression stability based on M values. GAPDH, ACTB, SDHA and TBP had higher stability, while HPRT, tRNA and B2M were variable in most tissues. TBP in intestinal segments (jejunum, ileum and colon) and SDHA in brain segments (cerebrum, cerebellum and brain stem) were particularly stable. HPRT ranked as the worst of the eight genes in the 13 tissues tested.
Comparison of gene expression levels between human and common marmoset leukocytes

Subsequently, we analyzed gene expression levels of four CD antigens (CD3ε, CD4, CD8α, and CD20) and ten cytokines, interleukin (IL)-1β, IL-2, IL-4, IL-5, IL-6, IL-10, IL-12β, IL-13, interferon (IFN)-γ and tumor necrosis factor (TNF)-α, in peripheral blood leukocytes from humans and common marmosets (Figure 4). The sequences of primers specific for these

Figure 1. Absolute copy numbers of candidate reference genes. The expression level of each gene in 13 tissues is shown as a logarithmic histogram of absolute copy numbers per µg of total RNA. Means and standard deviations of four individuals are indicated. GAPDH: glyceraldehyde-3-phosphate dehydrogenase; ACTB: actin, beta; rRNA: 18S ribosomal RNA; B2M: beta-2-microglobulin; UBC: ubiquitin C; HPRT: hypoxanthine phosphoribosyltransferase 1; SDHA: succinate dehydrogenase complex, subunit A; TBP: TATA-box binding protein.

doi:10.1371/journal.pone.0056296.g001

Figure 2. Gene expression stability and pairwise variation of candidate reference genes using geNorm analysis. (A) and (B): Average gene expression stability values M of the remaining reference genes during stepwise exclusion of the least stable gene in the different tissue panels are shown. Data are divided into two figures to avoid closely-packed lines. See also figure 3 for the ranking of genes according to their expression stability. (C) Pairwise variation analysis was used to determine the optimal number of reference genes for use in qPCR data normalization. The recommended limit for V value is 0.15, the point at which it is unnecessary to include additional genes in a normalization strategy.

doi:10.1371/journal.pone.0056296.g002
immune-related genes are shown in Table 2. The normalization factor for common marmoset leukocytes was calculated using GAPDH and UBC based on the geNorm analysis as described above. For human leukocytes, we found that the expression of all eight genes were stable (M value = 0.363), of which ACTB and HPRT had the best score (M value = 0.163, V2/3 = 0.062) and were selected for use. The expression levels of CD4 and IL-4 were significantly lower in common marmosets than in humans while those of IL-10, IL-12β and IFN-γ were significantly higher in common marmosets compared with humans. Of interest, the expression level of IL-4 was notably lower in common marmosets than humans, and was close to the detection limit. There was no statistical difference in the expression levels of the other genes tested between common marmosets and humans.

**Difference of CD4/CD8 ratio between humans and common marmosets**

We calculated ratios of the expression levels of CD4 to CD8 (CD4/CD8 ratio) in human and common marmoset leukocytes (Figure 5, left panel). CD4/CD8 ratios were significantly higher in human leukocytes compared with common marmoset leukocytes (mean ± sd, 0.59±0.22 vs. −0.49±0.41, P<0.01). To confirm the difference in CD4/CD8 ratios, we examined the proportion of CD4+ and CD8+ in CD3+ T cells by flow cytometric analysis. As shown in Figure 6, the rates of CD3+ cells in the lymphocyte gate were similar between common marmosets (30%) and humans (38%). However, the rates of CD4+ and CD8+ cells in CD3+ T cells was 36% and 61% in common marmosets, respectively, and 75% and 21% in humans, respectively. Similarly, the CD4/CD8 ratio was markedly different between common marmosets and humans (mean ± sd, 0.56±0.08 vs. 3.22±0.35, P<0.01) by qPCR. This indicated a good correlation between the results from FACS analysis and that of qPCR analysis. To examine whether the CD4/CD8 ratio is affected by age, we further performed FACS analyses with PBMCs from young and old marmosets (Table 3). The result showed that the inverted CD4/CD8 ratio was fairly constant among individuals and over ages.

**Figure 3. Ranking of gene expression stability of candidate reference genes using geNorm analysis.** Candidate reference genes are ranked in order of stability for each tissue with the two most stable genes at the left and the least stable at the right.

doi:10.1371/journal.pone.0056296.g003

doi:10.1371/journal.pone.0056296.g004
Difference in T helper 1 (Th1)/T helper 2 (Th2) balance between humans and common marmosets

We compared the ratios of expression levels of Th1-related genes (IFN-γ or IL-2) and Th2-related genes (IL-4) (IFN-γ:IL-4 or IL-2:IL-4 ratio) (Figure 5, middle and right panels). Both logarithmic values of the IFN-γ:IL-4 and IL-2:IL-4 ratios were negative in human leukocytes whereas those of common marmoset leukocytes, spleen, lymph node and thymus indicated positive values, showing a clear difference in the Th1/Th2 balance between humans and common marmosets.

Discussion

In the present study, we evaluated the expression stability of common marmoset housekeeping genes in various tissues. To the best of our knowledge, this is the first report of a systematic evaluation of potential reference genes in common marmosets. We chose eight commonly used classical housekeeping genes. Of all genes tested, rRNA showed the most abundant expression and UBC showed the lowest expression. The UBC gene contains multiple directly repeated ubiquitin coding sequences (i.e., polyubiquitin precursor protein) [17]. However, the primer set we used enabled amplification of the unrepeated sequence at the 5' region of the UBC gene only. Thus, low UBC expression in our data does not reflect the amount of ubiquitin C protein. B2M expression levels were markedly lower in brains and hearts than in other tissues. Resident brain cells normally express few or no MHC class I and B2M molecules [18–20]. In addition, B2M expression is upregulated by infection or autoimmune disease [21–23]. Therefore, in disorders with cellular infiltration such as inflammation (especially encephalitis) or cancer cell invasion, B2M expression levels may be significantly varied compared with normal tissue.
Thus, we predict that B2M may be unsuitable as a reference gene in many cases.

We assessed gene expression stability using the geNorm applet. As shown in Figure 2, geNorm analysis indicated that all tested genes were stable in each tissue. However, there were some trends in the stability ranking (Figure 3). For example, TBP were stable in each tissue. However, there were some trends in the high stabilities. Only FACS analysis, but not qPCR, was done with PBMCs from these three marmosets. DOI:10.1371/journal.pone.0056296.t003

We assessed gene expression stability using the geNorm applet. As shown in Figure 2, geNorm analysis indicated that all tested genes were stable in each tissue. However, there were some trends in the stability ranking (Figure 3). For example, TBP were stable in each tissue. However, there were some trends in the high stabilities. Only FACS analysis, but not qPCR, was done with PBMCs from these three marmosets. DOI:10.1371/journal.pone.0056296.t003

We observed that the expression levels of CD4 and IL-4 were lower in common marmosets than in humans. In contrast, the expression levels of CD4 and IL-4 were higher in common marmosets. We calculated PCR efficiency of each primer and found there was no great difference between primers for common marmosets and those for humans (Tables 1 and 2). Thus, the differences in the gene expression levels between common marmosets and humans are not attributable to the differences in PCR efficiency.

We also observed that the CD4:CD8 ratio and Th1/Th2 balance were inverted in common marmosets by qPCR analysis (Figure 5). In particular, we confirmed the inverted CD4:CD8 ratio by flow cytometric analysis (Figure 6 and Table 3). The inverted CD4:CD8 ratio was stable over age. Of interest, we noted that the Th1/Th2 balance is different between common marmosets and humans. Of interest, we noted that the inverted CD4:CD8 ratio was stable over age. Of interest, we noted that the Th1/Th2 balance is different between common marmosets and humans. This difference may affect host defense and/or disease susceptibility, which should be carefully considered in biomedical research using common marmoset models of various diseases. We believe our data will contribute to future investigations using common marmoset models of various diseases.

Table 3. CD8/CD4 ratio in PBMCs from young and old marmosets.

| Age  | Sex   | % positive | CD8/CD4 ratio |
|------|-------|------------|---------------|
|      |       | CD8        | CD4           |               |
| 3 month* | male  | 58.3       | 38.4          | 1.52          |
| 3 month* | female| 60.7       | 36.1          | 1.68          |
| 1.5 year | male  | 55.1       | 41.5          | 1.33          |

| 10 year* | male  | 58.6       | 37.8          | 1.55          |
| Mean ± sd |       | 57.1 ± 3.2 | 39.7 ± 3.4    | 1.45 ± 0.20   |

*Only FACS analysis, but not qPCR, was done with PBMCs from these three marmosets.

Thus, we predict that B2M may be unsuitable as a reference gene in many cases.

We assessed gene expression stability using the geNorm applet. As shown in Figure 2, geNorm analysis indicated that all tested genes were stable in each tissue. However, there were some trends in the stability ranking (Figure 3). For example, TBP were stable in each tissue. However, there were some trends in the high stabilities. Only FACS analysis, but not qPCR, was done with PBMCs from these three marmosets. DOI:10.1371/journal.pone.0056296.t003

We observed that the expression levels of CD4 and IL-4 were lower in common marmosets than in humans. In contrast, the expression levels of CD4 and IL-4 were higher in common marmosets. We calculated PCR efficiency of each primer and found there was no great difference between primers for common marmosets and those for humans (Tables 1 and 2). Thus, the differences in the gene expression levels between common marmosets and humans are not attributable to the differences in PCR efficiency.

We also observed that the CD4:CD8 ratio and Th1/Th2 balance were inverted in common marmosets by qPCR analysis (Figure 5). In particular, we confirmed the inverted CD4:CD8 ratio by flow cytometric analysis (Figure 6 and Table 3). The inverted CD4:CD8 ratio was stable over age. Of interest, we noted that the Th1/Th2 balance is different between common marmosets and humans, although we can only speculate on the cause of the difference. First, intestinal parasite infections may affect the Th1/Th2 balance by regulating expression of genes encoding cytokines [26–28]. In particular, protozoan parasites are potent stimulators of IFN-γ expression and Th1 responses [29]. Moreover, humans living in poor hygienic conditions in developing countries had higher Th1 cytokine levels compared with people in developed countries [30]. Although the common marmosets used in this study were maintained in specific pathogen-free conditions, we cannot rule out that such infectious agents may be one of a number of factors responsible for the difference in Th1/Th2 balance.

A second possible reason may be a difference in the number of cells producing the respective cytokines. As shown in Figure 6, the ratio of CD4+ T cells [31,32], its expression level may be influenced by the CD4:CD8 ratio. However, this is not true for all the cytokines tested. For example, the expression levels of IL-2, IL-5 and IL-13, largely produced by T cells, were not significantly different between common marmosets and humans. Therefore, we suggest that the CD4:CD8 ratio has little effect on Th1/Th2 balance. IL-10 is produced by T cells and monocytes [33] and IL-12β is naturally produced by dendritic cells and macrophages [34,35]. However, we could not verify these cell numbers in the common marmoset. Further studies are required to determine whether the numbers of cytokine-producing cells influence the expression levels of IL-10 and IL-12β.

Another possibility is genetic variation. Bostik et al., reported distinct sequence differences in the promoter region of the proximal region of cytokine genes including IL-4, IL-10, IL-12β and TNF-α among humans, macaque and mangabey monkeys, which affected regulation of cytokine synthesis [36]. Jeong et al., reported that the expression level of IL-4 was lower in monkeys (baboon and macaque) than in hominoids (human and chimpanzee) while the expression levels of IL-12β and the IFN-γ were higher in monkeys [37]. It is likely that Th1 dominant expression is common to primates other than hominoids and the difference in Th1/Th2 balance may be caused by genetic differences between common marmosets and humans.

The use of common marmoset is growing in popularity as a non-human primate model in many fields including autoimmune disease and infectious disease. In this study, we presented data regarding gene expression stabilities of common marmoset housekeeping genes and differences in the Th1/Th2 balance between common marmosets and humans. This difference may affect host defense and/or disease susceptibility, which should be carefully considered in biomedical research using common marmoset as an experimental model. We believe our data will contribute to future investigations using common marmoset models of various diseases.

Acknowledgments

We would like to acknowledge the efforts of Yasushi Ami in animal experiments. We also thank Ms. Hiro Yamada for technical assistance.

Author Contributions

Conceived and designed the experiments: YF TM K. Kitaura TS YH IK RS. Performed the experiments: YF K. Kitaura KS SS TT YK ST HK. Analyzed the data: YF RS. Contributed reagents/materials/analysis tools: K. Kumagai KS. Wrote the paper: TM K. Kitaura TS YH IK RS.
