Carbapenems have been standard treatments for multidrug-resistant gram-negative bacilli infections since 1985, when they were approved for clinical use in the United States (https://www.accessdata.fda.gov/drugsatfda_docs/label/2016/050587s074lbl.pdf). Carbapenem-resistant organisms (CROs) are a growing public health concern as carbapenemase-producing CROs become more common (1). Several recent reports describe CROs carrying multiple carbapenemase genes (multi-CPOs) (2–8). We describe multi-CPOs reported to the Centers for Disease Control and Prevention (CDC; Atlanta, GA, USA) during 2012–2019.

The Study
CDC receives reports of carbapenemase-producing CROs from health departments, public health laboratories, healthcare facilities, and isolates sent to CDC for confirmatory testing. In 2016, CDC established the Antibiotic Resistance Laboratory Network (AR Lab Network), a national network of 55 public health laboratories that test carbapenem-resistant Enterobacterales (CRE), carbapenem-resistant Pseudomonas aeruginosa (CRPA), and carbapenem-resistant Acinetobacter baumannii (CRAB) isolates for carbapenemase genes.

We reviewed CDC and AR Lab Network reports of multi-CPOs identified during January 1, 2010–April 30, 2019. We defined a multi-CPO case as Enterobacterales, Pseudomonas spp., or A. baumannii isolated from any specimen source and carrying genes encoding >1 carbapenemase routinely tested for at CDC and the AR Lab Network (CRE, CRPA, and CRAB isolates were tested for Klebsiella pneumoniae carbapenemase [KPC], New Delhi metallo-β-lactamase [NDM], Vero-nia integron-encoded metallo-β-lactamase [VIM], active-on-imipenem metallo-β-lactamase [IMP], and ox-acillinase [OXA]-48–like β-lactamases; CRAB isolates also were tested for OXA-23, OXA-24/40, and OXA-58–like β-lactamases). Whole-genome sequencing (WGS) was conducted on a subset of isolates (Appendix, https://wwwnc.cdc.gov/EID/article/27/9/21-0456-App1.pdf). We defined an incident case as the first isolation of a unique organism–carbapenemase combination in each patient.

As part of routine public health investigations, health departments reviewed medical records and laboratory reports for patient demographic data and risk factors for exposure. We conducted descriptive analyses using SAS version 9.4 (https://www.sas.com) and calculated Pearson χ² score using SPSS Statistics 21.0 (IBM, https://www.ibm.com).

During January 2010–April 2019, a total of 151 multi-CPO isolates, including those from 105 incident cases, were identified in 100 unique patients; the first case was identified in October 2012 (Table 1; Appendix Tables 1,2). Among 89 (84.8%) incident cases...

DOI: https://doi.org/10.3201/eid2709.210456
WGS identified 21 isolates harboring blaNDM, 9 of Escherichia coli, and 11 of Klebsiella pneumoniae cases, identifying 6 sequence types of Enterobacter and blaKPC.

Incident cases were reported in 29 US states and the District of Columbia. Enterobacterales accounted for 96 (91.4%) of the incident multi-CPO cases; in addition, 7 (6.7%) were Pseudomonas spp. and 2 (1.9%) were Acinetobacter baumannii. Among 96 incident Enterobacterales cases, the most common (46; 47.9%) organism–gene combination was K. pneumoniae harboring blaNDM and blaOXA-48-like.

WGS was conducted on 46 isolates from incident cases, identifying 6 sequence types of Enterobacter cloacae, 9 of Escherichia coli, and 11 of K. pneumoniae. WGS identified 21 isolates harboring blaNDM, 16 harboring blaKPC, 16 harboring blaOXA-48, and 11 harboring blaIMP (Appendix Table 2). In total, 8 incident cases were associated with 2 separate clusters at acute care hospitals.

The median age of patients at the time of multi-CPO identification was 63 years (range 2–94 years). Among 93 incident cases with available data, 62 (66.7%) occurred in patients who had traveled internationally in the 12 months before their incident culture. Among patients with a history of international travel, most (89.5%) had received inpatient healthcare while abroad. Association with international travel varied by carbapenemase combination; among 59 incident cases with available data that harbored blaNDM and blaOXA-48-like, 47 (79.7%) occurred in patients who reported international travel; only 5/19 (26.3%; p<0.01) incident cases that harbored blaKPC and blaNDM occurred in patients who reported international travel. Among the 80 incident cases with available data, 14 (17.5%) occurred in patients with a history of solid organ or bone marrow transplantation before their incident culture (Table 2).

Multi-CPOs in this convenience sample were identified in many states and included diverse organisms, sequence types, and carbapenemase gene combinations and variants, suggesting that clonal spread is not responsible for their emergence. Variants harboring blaKPC and blaNDM were uncommon in the United States; we also identified history of solid organ or bone marrow transplant as a potential risk factor.

Receiving healthcare abroad and, more recently, international travel without medical care are risk factors for acquiring carbapenemase-producing organisms among patients in the United States (9). However, in this study, one third of cases occurred in persons without known recent travel outside the United States; for some carbapenemase combinations, such as isolates harboring blaKPC and blaNDM, most cases occurred in patients who had not recently traveled internationally. In addition, identifying facility clusters raises further concerns about dissemination of these multidrug-resistant organisms among healthcare facilities in the United States.

The emergence of multi-CPOs has clinical, laboratory testing, and public health implications. The ceftazidime/avibactam, meropenem/vaborbacatin, and imipenem/cilastatin/relebacatin combination therapies have increased treatment options for CREs that produce KPC and OXA-48-like carbapenemases; growth in the proportion of isolates that co-harbor

¶¶Solid organ or bone marrow transplants; of 75 unique patients who contributed 80 incident cases with complete data.
###Of includes 17 unique patients who contributed 17 incident cases with complete data.
bla_{NDM} jeopardizes the usefulness of these therapies. We noted 1 P. aeruginosa isolate harboring bla_{NDM} and bla_{IMP-1}; this isolate was panresistant to all antimicrobial drugs tested (12). A high proportion (17.5%) of cases occurred among patients with history of solid organ or bone marrow transplantation before their index culture, a population for whom CRO infections are associated with worse outcomes than patients without transplants (13,14). In comparison, only 31% of patients with CRE reported to the Multi-Site Gram-Negative Surveillance Initiative at CDC during 2012–2019 had a history of transplant before their positive culture (15; I. See, CDC, pers. comm., 2021 Jan 19); whether multi-CPOs are emerging in this population requires careful monitoring. Finally, hierarchical testing algorithms, in which testing is halted after detection of an initial carbapenemase, might not identify additional, less common carbapenemases (e.g., hierarchical testing might not identify bla_{NDM} in an isolate with bla_{KPC} and bla_{VIM}).

The first limitation of our analysis is that these data represent a passively reported convenience sample during a period in which multiple changes in testing practices, including the establishment of the AR Lab Network, occurred. For this reason, we cannot determine whether multi-CPOs became more common during the evaluation period. Second, CROs from patients with a history of healthcare abroad might have been selected for mechanism testing, biasing detection toward this risk factor; bias might have been more influential early in the investigation period, when testing resources were limited. Finally, this analysis did not systematically document outpatient healthcare exposures and residence in long-term care facilities, which also might be relevant sources of exposure; 1 case in this analysis was associated with invasive urologic procedures abroad (7).

Conclusions
Multi-CPOs in healthcare facilities are an emerging concern in the United States. Although hospitalization outside the United States was the most common risk factor, we found a substantial proportion of cases that were probably acquired in healthcare facilities in the United States. Several measures might slow further spread. First, screening patients who were recently hospitalized outside the United States can help prevent additional introductions of carbapenemase genes not commonly found in the United States. Second, molecular testing to identify carbapenemase genes should not use hierarchical algorithms. Finally, when a multi-CPO is identified, public health officials should assess for potential transmission (https://www.cdc.gov/hai/containment/guidelines.html).

Acknowledgments
We thank our state and local health department partners for providing information from their public health response work, including Eleanor Adams, Melissa Anacker, Michael Anderson, Sandi Arnold, Rachana Bhattacharai, Emily Blake, Justin Blanding, Janine Bodnar, Erin Breaker, the California Department of Public Health—Microbial Diseases Laboratory, Theresa Canulla, Rebekah Carman, Savannah Carrico, Melanie Chervony, Kaitlyn Chorbi, Kailee Cummings, Jennifer Dale, Thi Dang, Marisa D’Angeli, Jonathan Daniels, Catherine Dominguez, Andrea Flinchum, Bobbie Jean Garcia, Michael Goschiminski, Shermaly Greene, Annastasia Gross, Alison Laufer Halpin, Ishrat Kamal-Ahmed, Marion Kainer, Kelly Kauber, Alyssa Kent, Elizabeth Kim, Cara Bicking Kinsey, Sarah Kogut, Pat Kopp, Adrian Lawsin, James Lewis, Ruth Lynfield, Jennifer MacFarquhar, Patricia McAuley, Susannah McKay, Sara McNamara, the Maryland Public Health Laboratory Antibiotic Resistance Lab Network Working Group, Derek Miller, Shannon Morris, Jeanne Negley, Julie Paoline, Brittany Pattee, Sean O’Malley, Naveen Patil, Elizabeth Nazarian, Caitlin Pedati, Amy Recker, Jacqueline Reuben, Emily Schneider, Amanda Smith, Elizabeth Soda, Kevin Spicer, Emily Snabely, Bryna Stacey, Maureen Tierney, Angela Tang, Michael Tran, Paula Snippes Vagnone, Christine Wagner, JoAnna Wagner, and Phillip Weeber.

S.H.-S. received a Merck Investigational Studies Program Grant (November 2019–November 2020) for work on carbapenem-resistant Enterobacteriaceae surveillance at the California Department of Public Health (Los Angeles, California, USA). M.K. has a US patent application (application no. 16/615,725) filed November 21, 2019 for detection of bla_{NDM} antimicrobial resistance genes.

About the Author
Dr. Ham is a public health physician at the National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia, USA. His primary research focus is antimicrobial resistance among gram-negative and gram-positive bacteria.

**EID podcast**

**A Decade of Fatal Human Eastern Equine Encephalitis Virus Infection, Alabama**

After infection with eastern equine encephalitis virus, the immune system races to clear the pathogen from the body. Because the immune response occurs so quickly, it is difficult to detect viral RNA in serum or cerebrospinal samples.

In immunocompromised patients, the immune response can be decreased or delayed, enabling the virus to continue replicating. This delay gave researchers the rare opportunity to study the genetic sequence of isolated viruses, with some surprising results.

In this EID podcast, Dr. Holly Hughes, a research microbiologist at CDC in Fort Collins, Colorado, describes a fatal case of mosquitoborne disease.

Appendix Methods

Laboratory Methods for Molecular Detection of Carbapenemase Genes

Molecular detection of targeted carbapenemase genes was conducted using ≥1 PCR-based protocols and platforms, namely the Centers for Disease Control and Prevention (CDC)’s laboratory-developed and validated methods, Gene Xpert Carba-R (Cepheid, https://www.cepheid.com), ARM-D β-Lactamase (Streck, https://www.streck.com), and Verigene Gram-Negative Blood Culture System (Nanosphere, http://www.nanosphere.us). Laboratories used the modified carbapenem inactivation method (mCIM) or CarbaNP as phenotypic tests to determine whether an organism is carbapenemase-producing (https://arpsp.cdc.gov/resources/arln-psp-technical-appendix.pdf).

Changes in Laboratory Testing Protocols During Investigation Period

Beginning in January 2017, laboratories in the Antibiotic Resistance Laboratory Network tested for New Delhi metallo-β-lactamase, Klebsiella pneumoniae carbapenemase, Verona integron-encoded metallo-β-lactamase, active-on-imipenem metallo-β-lactamase, and oxacillinase-48–like β-lactamases. Not all laboratories initially tested all isolates for all gene targets. Some laboratories instituted hierarchical testing algorithms; if blakpc and blandm were not detected, the isolates were tested for additional targets validated in their testing menu. If carbapenemase-producing (i.e., testing positive by the modified carbapenem inactivation method or CarbaNP) isolates were negative for all targets tested, the laboratories forwarded the isolate to their regional laboratory or CDC for additional characterization. In November 2017, CDC deployed PCR specific to additional blaimp variants not identified by Gene Xpert Carba-R. In November 2018, CDC deployed PCR that detects additional oxacillinases commonly associated
with *Acinetobacter* spp. (i.e., *bla*OXA-23, *bla*OXA-24/40, *bla*OXA-58). After approval, these assays were made available to the Antibiotic Resistance Laboratory Network and were validated and implemented at different times by laboratories in the network.

**Whole-Genome Sequencing (WGS) Methods**

Results were obtained from CDC and 4 state public health laboratories (SPHLs) that commonly performed WGS on carbapenemase-producing, carbapenem-resistant organisms harboring multiple carbapenemase genes. We report results on carbapenemase gene variants and sequence types determined by multilocus sequence typing (MLST).

**WGS at SPHL 1**

Isolates were extracted using the Qiagen DNeasy Blood & Tissue kit (QIAGEN, https://www.qiagen.com) and DNA libraries were prepared using the PulseNet Illumina Nextera XT protocol before being loaded on the Illumina MiSeq (Illumina, https://www.illumina.com). Carbapenemase variants were identified using ABRicate (https://github.com/tseemann/abricate). MLST was performed at CDC.

**WGS at SPHL 2**

DNA was extracted with the Qiagen DNeasy Blood & Tissue Kit (QIAGEN and libraries were prepared with the Illumina Nextera XT Kit and sequenced with a MiSeq version 3.0 600-cycle Kit (Illumina). Reads were assembled with CLC Genomics Workbench (QIAGEN), and assemblies were submitted to the ResFinder tool for antimicrobial resistance gene prediction or the MLST tool for in silico MLST.

**WGS at SPHL 3**

Genomic DNA was extracted from isolates using the DNeasy Blood & Tissue Kit on a QIAcube (QIAGEN). Sequence libraries were prepared using the Nextera XT DNA Sample Preparation Kit and sequenced on the Illumina MiSeq system (Illumina).

Raw Illumina reads were processed with Trimmomatic version 0.38 (1) and paired, 250 bp reads were then de novo assembled into contigs with SPAdes version 3.12.0 (2). Assembly quality was assessed using quantitative measurements, including BUSCO version 3.1.0 (3,4), before MLST with mlst v2.16.2 (https://github.com/tseemann/mlst) and AR gene identification with ABRicate version 0.8.13 (https://github.com/tseemann/abricate). Final analysis of the AR
genes in the genome assembly compared gene identification between the National Center for Biotechnology Information Bacterial Antimicrobial Resistance Reference Gene Database (5), ResFinder (6), and Comprehensive Antibiotic Resistance Database (7) to determine the best matches.

WGS at SPHL 4

DNA extraction was performed on the Magnapure 24 automated platform (Roche Molecular Systems, https://www.roche.com). Whole genome sequencing was performed using Illumina Miseq (Illumina). Following sequencing, de novo assembly was performed using CLC Genomics Workbench (QIAGEN), and the resistance gene profile is analyzed through CGE’s Resfinder database. MLST was performed using the Linux-based program MLST by Torsten Seeman, which uses the available schemes found in pubmlst (https://github.com/tseemann/mlst).

WGS at CDC

Genomic DNA was extracted using Promega Maxwell 16 MDx Instrument and Maxwell 16 Cell Low Elution volume DNA Purification Kit (Promega Corporation, https://www.promega.com). WGS was performed using the Illumina MiSeq System and MiSeq Reagent version 2.0 kit, generating 2 × 250 paired-end reads (Illumina).

The WGS data was processed with the QuAISAR-H pipeline (Quality, Assembly, species Identification, Sequence typing, Annotation, Resistance mechanisms for Healthcare pathogens, https://github.com/DHQP/QuAISAR_singularity/). The pipeline includes species verification using pyani (8), identification of MLST using PubMLST definitions (9), and antibiotic resistance gene calling using GAMMA (https://github.com/rastanton/GAMMA) against a database constructed from the nonredundant entries in the ARG-ANNOT (10), NCBI AMRFinder (5), and ResFinder (11) antimicrobial resistance databases.

†Three *K. pneumoniae* incident cases harboring bla\textsubscript{NDM} and bla\textsubscript{OXA-48-like} were associated with an outbreak at an acute care hospital. Of the 3 isolates, 2 underwent WGS; they were identified as ST147 harboring bla\textsubscript{NDM-5} and bla\textsubscript{OXA-181}. In a separate cluster at an acute care hospital, an additional 5 incident cases harboring bla\textsubscript{KPC} and bla\textsubscript{NDM} (3 *E. cloacae* and 2 *K. pneumoniae*) were identified during a 16-mo period. WGS of 4 of these 5 isolates demonstrated that all harbored bla\textsubscript{KPC-3} and bla\textsubscript{NDM}, and that 2 isolates were *E. cloacae* ST729, 1 was *E. cloacae* ST114, and 1 was *K. pneumoniae* ST163. Excluding these 8 cases linked to clusters, 97 incident cases were identified in 28 US states and the District of Columbia; only 18 (19.6%) incident cases with the same organism–mechanism combination were identified from the same state within the same 90-d period, making it unlikely that small outbreaks were the primary cause of cases. IMP, active-on-imipenem metallo-β-lactamase; KPC, *Klebsiella pneumoniae* carbapenemase; NDM, New Delhi metallo-β-lactamase; OXA, oxacillinase; ST, sequence type; VIM, Verona integron-encoded metallo-β-lactamase; WGS, whole-genome sequencing.

‡WGS did not detect bla\textsubscript{OXA-48-like}. The mobile genetic element carrying bla\textsubscript{OXA-48-like} might have been lost before sequencing, which was conducted ≈3–5 wks after initial characterization.

§WGS did not detect bla\textsubscript{NDM}. The mobile genetic element carrying bla\textsubscript{NDM} might have been lost before sequencing, which was conducted ≈3–5 wks after initial characterization.
