Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
The nucleocapsid protein of SARS-associated coronavirus inhibits B23 phosphorylation

Abstract

Severe acute respiratory syndrome-associated coronavirus (SARS-CoV) is responsible for SARS infection. Nucleocapsid (N) protein of SARS-CoV encapsidates the viral RNA and plays an important role in virus particle assembly and release. In this study, the N protein of SARS-CoV was found to associate with B23, a phosphoprotein in nucleolus, in vitro and in vivo. Mapping studies localized the critical N sequences for this interaction to amino acid residues 175–210, which included a serine/arginine (SR)-rich domain. In vitro phosphorylation assay showed that the N protein inhibited the B23 phosphorylation at Thr199.

Introduction

Severe acute respiratory syndrome (SARS) is a human infectious disease that first emerged in Southern China in mid-November 2002 [1]. A novel coronavirus named SARS-associated coronavirus (SARS-CoV) was identified as the causative agent of SARS [2]. The nucleocapsid (N) protein of SARS-CoV consists of 422 amino acids and shares 20–30% homology with N proteins of other coronaviruses [3]. The N protein is the major antigen recognized by convalescent antisera and can be used as a diagnostic marker for the detection of SARS [4]. The N protein is reported to be phosphorylated [5] and the phosphorylation plays a role in the immunoreactivity and specificity of SARS-CoV N protein [6].

The N protein plays a role in viral packaging, viral core formation and regulation of signal transduction. The N protein of SARS-CoV encapsidates the viral RNA and binds N protein itself and the membrane protein of SARS-CoV [7–9]. SARS-CoV N protein has been reported to localize in the cytoplasm of SARS-CoV infected cells with a weak presence in the nucleus [10]. N protein also has the capability to regulate cellular signal pathways such as arresting cell cycle progression [11], inducing apoptosis and actin reorganization [12] and activating the AP-1 signal transduction pathway [13]. It has previously been shown that the N protein of SARS-CoV interacts with cellular proteins, including cyclophylin A [14], human cellular heterogeneous nuclear ribonucleoprotein A1 [15], human ubiquitin-conjugating enzyme [16] and CDK–cyclin complex proteins [11].

The nucleolar phosphoprotein B23 is originally identified as a high-level phosphoprotein in granular regions of the nucleolus [17]. B23 protein can bind nucleic acids [18] and physically interact with maturing preribosomal ribonucleoprotein particles [19]. This protein also functions as a shuttle protein in protein nuclear import [20,21]. It is reported that B23 protein forms a specific complex with several viral proteins such as Rex protein of human T-cell leukemia virus [22], Rev protein [23], and Tat protein [24] of human immunodeficiency virus and Hepatitis delta virus.
Materials and methods

Plasmids construction. The full-length SARS-CoV N gene and the truncated mutants N1 (1–225), N2 (1–293), N3 (210–422), N4 (175–422) and N5 (353–422) were obtained by polymerase chain reaction (PCR) using the plasmid pGEMT-N containing the full-length N gene as a template (GenBank Accession No. AY365036). The PCR products were cloned into the vector pET-GST. This vector was used for expression of GST fusion proteins.

The human B23.1 gene in pBluescriptII SK plasmid was kindly provided by Dr. Stephan W. Morris (St. Jude Children’s Research Hospital, USA). The B23 coding sequence was amplified by PCR and then cloned into the vectors of pE-T-GST and pET-His. pET-His vector was used for expression of proteins with a 6His-tag at the C-terminus.

All the recombinant plasmids were confirmed by PCR, restriction digestion and DNA sequencing.

Indirect immunofluorescence assay and confocal microscopy. HeLa cells grown on coverslips were transfected with 2 μg of pcDNA3 vector or pcDNA3-N plasmid [10] for 6 h. At 24 h post-transfection, cells were fixed with ice cold 50% methanol–50% acetone at −20 °C. Coverslips were incubated for 1 h at 37 °C with anti-N antibody [4] and anti-B23 antibody (Sigma–Aldrich, St. Louis, MO), followed by incubation with FITC-conjugated goat anti-rabbit IgG (Sigma) and TRITC-conjugated goat anti-mouse IgG (Sigma) for 1 h at 37 °C, respectively. The final fluorescence images were visualized under laser confocal scanning microscope (Leica Laser Technik, Germany) with appropriate filters.

Expression and purification of recombinant proteins. Recombinant 6His-tagged B23 protein, GST-fused SARS-CoV N protein and deletion mutants were expressed in Escherichia coli (E. coli) BL21 (DE3) cells after induction with 1 mM IPTG for 6 h in LB-medium at 37 °C. The bacterial cells were spun down and resuspended in lysis buffer (20 mM Tris–HCl [pH 7.9], 500 mM NaCl, 5 mM Imidazole, 1 mM NaF and 1 mM PMSF) and then sonicated and centrifuged at 12,000g at 4 °C for 30 min. The recombinant proteins were purified by a Ni-NTA affinity column (Qiagen, Valencia, CA, USA) according to the manufacturer’s instructions.

Preparation of cell lysates and GST pull-down assay. To prepare HeLa cell lysates, approximate 10^7 HeLa cells were harvested, washed with PBS buffer and sonicated in cellular lysis buffer (50 mM Tris–HCl [pH 7.4], 150 mM NaCl, 1 mM EDTA, 10% glycerol, 1 mM PMSF, and 1 mM DTT) with 1× protease inhibitor cocktail (Sigma, St. Louis, MO). The lysates were centrifuged at 12,000g for 20 min at 4 °C.

Equal amount of either GST or GST-fused proteins bound to glutathione–sepharose beads was mixed with 6His-tagged B23 protein or HeLa cell lysates. After incubation for 3 h at room temperature, the beads were washed five times with PBS. Proteins bound to the beads were removed by boiling in 4× SDS sample buffer for 10 min. Proteins were analyzed by SDS–PAGE and detected by Western blot analysis.

Results

Co-localization of N protein and cellular protein B23

Previous study has demonstrated that SARS-CoV N protein bears three nuclear localization signals (NLS) and a nuclear export signal, acting as a shuttle protein between nucleus and cytoplasm [10]. Since B23 protein can bind NLS and facilitate protein nuclear import [20,21], we investigated the possibility of co-localization of these two proteins in pcDNA3-N transfected HeLa cells by indirect immunofluorescence staining using anti-N antibody and anti-B23 antibody, respectively, visualized under laser confocal scanning microscope. Consisting with previous findings [10], N protein was localized in the cytoplasm, mostly in perinuclear region (Fig. 1d). B23 protein was...
localized both in cytoplasm and in nucleus and the N protein did not affect the B23 localization (Fig. 1b and e). The overlayed result indicated that the SARS-CoV N protein co-localized with B23 protein in the perinuclear region of HeLa cells (Fig. 1f). The same experiment was repeated in VeroE6 cells and a similar result was observed (data not shown).

The interaction between N protein and B23 protein in vitro and In vivo

Co-localization of SARS-CoV N protein and cellular B23 protein suggested that N protein might interact with B23 protein. To examine this possibility, a protein binding assay of GST-N fusion protein to cellular B23 protein was performed. As shown in Fig. 2A, the endogenous B23 was pulled-down by GST-N fusion protein but not by GST protein.

Because both N protein and B23 protein bind RNA [7,18], it is possible that N and B23 protein interact through RNA. To test whether RNA was required for the interaction between B23 and N protein, the lysates of HeLa cells were treated with RNaseA prior to the GST-pull down assay. This treatment did not affect the amount of B23 bound to GST-N protein compared to that of the untreated extracts (Fig. 2B), indicating that N protein interacted with B23 independent of cellular RNA.

GST pull-down assay was repeated using E. coli-expressed 6His-B23 protein instead of HeLa cell lysates and a similar result was obtained (data not shown). In addition, the GST pull-down assay using GST-B23 protein and 6His-N protein was performed. As what expected, N protein could bind GST-B23 fusion protein, but no N protein could bind GST protein alone (Fig. 2C). All the results above demonstrated that N protein of SARS-CoV interacted directly with B23 in vitro.

To investigate whether the interaction between N protein and B23 protein occurred in N-expressing cells, we performed co-immunoprecipitation assay using anti-N antibody to co-immunoprecipitate the N protein and any other possible interacting proteins in cellular extracts of pcDNA3-N transfected HeLa cells. The bound proteins were detected by anti-B23 antibody. Consisting with the above results, B23 protein together with N protein could be co-immunoprecipitated by the anti-N antibody while no B23 was precipitated in the control sample (Fig. 2D), confirming that SARS-CoV N protein interacted with B23 protein in vivo.

Mapping the B23-binding domain of SARS-CoV N protein

To identify the B23-interactive region within the N protein, a series of deletion mutants were generated (Fig. 3A). As shown in Fig. 3B, the mutant N1 (1–225), N2 (1–293) and N4 (175–422) bound B23 (Fig. 3C, lanes 3, 4, and 6),
Thr199. The above results indicated that the N protein inhibited the phosphorylation of B23 at Thr199. The GST-N protein exhibited an inhibitory effect on the phosphorylation of B23. As shown in Fig. 4B, GST-N protein did not affect the phosphorylation of B23 at Thr199 but GST-N protein exhibited an inhibitory effect on the phosphorylation of B23. The above results indicated that the N protein inhibited the phosphorylation of B23 at Thr199.

Discussion

In our previous research, we found that SARS-CoV N protein contained three NLS motifs and a nuclear export signal, acting as a shuttle protein between nucleus and cytoplasm, and it could arrest the cell cycle progression [10]. B23 protein can bind NLS, facilitate protein nuclear import and play a role in centrosome duplication during cell cycle progression [20,21,26]. Therefore, we studied the interaction of these two proteins and the functional effect of this interaction. We discovered that B23 interacted with SARS-CoV N protein in vitro and in vivo. Somewhat surprisingly, we mapped the B23-binding domain within the N protein to a SR-rich domain (aa 175–210) rather than any putative NLS motif. B23 usually plays a role in nuclear import of the viral proteins to which it binds [24,25]. However, according to our previous study [10], the deletion mutant N4 (175–422), which could interact with B23 protein, was shown to localize in cytoplasm and the deletion mutant N1 (1–225), which also could interact with B23 protein, localized in the cytoplasm and nucleus. Moreover, overexpression of B23 protein in HeLa cells did not change the cytoplasmic localization of N protein of SARS-CoV (data not shown). Therefore, we speculated that unlike other B23-binding viral proteins, the binding of N protein with B23 protein might not involve in sub-cytoplasmic localization of N protein.

B23 is also identified as one of the substrates of CDK2/cyclin E and plays a role in centrosome duplication during cell cycle progression. B23 associates specifically with unduplicated centrosomes and this association is controlled by CDK2–cyclin E-mediated phosphorylation. B23 loses its affinity to centrosomes in its phosphorylated form. Dissociation of the centrosomal B23 is essential for the centrosome to initiate duplication [26]. The Thr199 amino acid in B23 is the phosphorylation site essential in this regulation of centrosome duplication [27]. In our previous research, we have shown that the N protein of SARS-CoV can arrest cell cycle progression [10], which is in accordance with the result of Surjit et al. [11]. Here we demonstrated that N protein inhibited the phosphorylation of B23 at Thr199 in HeLa cells and in vitro phosphorylation assay (Fig. 4). Therefore, we hypothesize that when N protein interacts with B23, N protein may competitively inhibit the interaction of B23 and CDK2 kinase or the phosphorylation site of B23 may be blocked by the bound N protein, resulting in lack of phosphorylation of B23 protein. This can lead to cell cycle arresting since the centrosome can not initiate duplication. In this model, the N protein of SARS-CoV manipulates the host cell cycle machinery by acting as a competitive inhibitor to B23 phosphorylation through its interaction with B23 protein.

B23 protein has been shown to participate in various other cellular events such as ribosome assembly [19] and acting as a molecular chaperone [28]. The interaction of B23 and N protein of SARS-CoV might influence the ribosome biogenesis in cells and resulted in suppression of host gene expression to create a more favorable milieu for virus survival. This interaction also might affect the molecular chaperoning activities of B23 and lead to incorrect protein folding.
Acknowledgments

We thank Dr. Stephan W. Morris (St. Jude Children’s Research Hospital, USA) for providing B23.1 gene plasmid. We thank Dr. BiaoHe and Dr. LinGuo for critically revising the manuscript. We also thank Ying Hu for technical assistance.
