Abstract: The method of determining probability thresholds of three-way decisions (3WDs) has always been the key of research, especially in the current environment with a large number of data and uncertainties. Among these problems, there will be correlation and similarity between them. In the light of these problems, the loss function with Probabilistic Linguistic Terms Sets (PLTSs) is introduced in the paper, and then we propose a PLTS evaluation-based approach to determine the thresholds and derive 3WDs. According to the definition and characters of PLTSs, the PLTSs loss function matrix is constructed firstly. Then using the equivalent model of Decision-theoretic rough sets (DTRSs), we construct the equivalent model (i.e., the $\alpha_{opt}$-model and the $\beta_{opt}$-model, which are symmetrical) and try to find the optimal solution to determine the thresholds. Based on that, we propose a novel three-way decision approach under PLTSs evaluations. Finally, the validity of the method is verified by an example.

Keywords: three-way decisions; probability thresholds; probabilistic linguistic terms sets; equivalent model

1. Introduction

Three-way decisions, which were first proposed by Yiyu Yao in the early 1990s, is a new decision analysis method of dealing with inaccurate and incomplete information [1]. As an important promotion of traditional two-way decisions, it provides an effective strategy, which trisects decision problems into three decision semantics with positive domain (accept decision), negative domain (reject decision), and boundary domain (delayed decision) to solve complex decision problems. Based on the rough set theory model, Yao introduced the Bayes risk decision method to analyze and evaluate the risk cost of various decisions and then obtained the minimum risk cost evaluation decision result among them [2]. Nowadays, theories and methods related to three-way decisions have attracted widespread attention from scholars [3–7]. Moreover, it has been successfully applied to many disciplines and fields, such as attribute reduction [8–10], paper review [11], recommendation system [12,13], granular computing [3,14], multi-attribute decision-making [15], fuzzy clustering [16,17], concept learning [18,19], medical diagnosis [20] and face recognition [21].

In three-way decisions, determining the threshold pair $\alpha$ and $\beta$ is an important problem. Up to now, fruitful researches have been achieved under the thorough study of many scholars [2,22–24]. Yao constructed a decision rough set model based on Bayesian theory and then derived an analytical solution of probability threshold directly, which provided a reasonable semantic explanation for the threshold pair of Probabilistic Rough Sets model [2]. Based on this, Li et al. deduced the expression of three decision thresholds—optimistic tendency, pessimistic tendency and neutral tendency—by introducing the risk preference of decision-makers [22]. Based on the research on the relationship between loss risk and threshold parameters in the basic model, Jia et al. proposed an optimization model and designed an adaptive learning algorithm to solve the model to determine the probability...
threshold [25]. In addition, based on the Game-Theoretic Rough Set model, a method of determining three decision probability thresholds was proposed by Azam et al [26]. Obviously, the above methods are mainly used to study the loss function with real value. Due to the uncertainty, complexity, and fuzziness of the real environment in practical application, decision-makers (DMs) or experts often give fuzzy or uncertain evaluation forms rather than specific real value evaluation in the loss function [27,28], such as interval number (INs), triangle fuzzy number (TFs), Intuitionistic Fuzzy Sets (IFSs), and Pythagorean Fuzzy Sets (PFSs). Therefore, many scholars begin to extend the classical decision-theoretic rough sets (DTRSs) to the fuzzy or uncertain environment; they have put forward many extended decision rough set models in recent years.

Note that for multi-attribute decision-making and evaluation problems, such as project evaluation, personnel assessment, medical diagnosis, the current solving trend is still the logical inference based on prior knowledge. However, due to the complexity of objective things and the limitations of personal knowledge, it is impossible to describe objective things and their attribute characteristics accurately. In this case, fuzzy linguistic evaluation has gradually become a new choice for DMs. According to the flourishing development of fuzzy set theory, a large number of scholars have proposed a series of concepts: Linguistic Term Sets (LTSs) [29], Hesitant Fuzzy Sets (HFSs) [30], Hesitant Fuzzy Linguistic Term Sets (HFLTSs) [31], Probabilistic Linguistic Term Sets (PLTSs) [32], and Interval-valued Probabilistic Linguistic Term Sets (IVPLTSs) [33]. By describing the evaluation preference of decision-makers and measuring the degree of preference comprehensively, PLTSs (Qi, 2016) makes the decision result more reliable and practical [32]. Some progress on the application of PLTSs to decision-making has been recently; however, it is still in its infancy. Therefore, under the evaluation of PLTSs, it is also an important research problem that how to determine the threshold pair \( \alpha \) and \( \beta \).

This paper proposed a novel three-way decision approach under PLTSs evaluations to determine the threshold pair. The reminder of this paper is organized as follows. Section 2 briefly reviews the concepts of PLTSs, DTRSs, and the equivalent model of DTRSs. In Section 3, we describe the three-way decision problems based on evaluation of Probabilistic linguistic Term Sets. Based on the evaluation of PLTSs to decision-making has been recently; however, it is still in its infancy. Therefore, under the evaluation of PLTSs, it is an also important research problem that how to determine the threshold pair \( \alpha \) and \( \beta \).

2. Preliminaries

In this section, we introduce some basic concepts and notations, such as PLTSs and their properties as well as DTRs.

2.1. Probabilistic Linguistic Term Sets

**Definition 1.** Ref. [34] Let \( S \) be a set with odd elements, a linguistic term set is defined as

\[
S = \{s_\alpha, \alpha = 0, 1, \ldots, \tau\},
\]

where \( \tau \) is a positive integer, \( s_\alpha \) is a linguistic term, and \( s_0 \) and \( s_\tau \) represent the minimum and maximum of linguistic evaluation, respectively.

Based on Definition 1, we have

1. Ordering: if \( \alpha > \beta \), then \( s_\alpha > s_\beta \).
2. Complementarity: if \( \alpha + \beta = \tau \), then \( \text{neg}(s_\alpha) = s_\beta \).

**Definition 2.** Ref. [34] Let \( s_\alpha \) and \( s_\beta \) be two linguistic term sets: \( s_\alpha, s_\beta \in S \), parameter \( \lambda, \lambda_1, \lambda_2 \in [0, 1] \); then, we have the following operation rules:

\[
\begin{align*}
(1) s_\alpha \bigoplus s_\beta &= s_\beta \bigoplus s_\alpha = s_{\alpha+\beta}
\end{align*}
\]
As a linguistic term set can only represent a range of evaluation levels rather than an accurate level, DMs seem to hesitate about choosing from multiple decisions. Therefore, the hesitant fuzzy linguistic term set was put forward by Rodriguez et al. [35].

**Definition 3.** Ref. [35] Let $S$ be a set of the evaluation objects, $C$ be an attribute set of the evaluation objects, and $S = \{s_\alpha, \alpha = 0, 1, \cdots, \tau\}$ be a LTS, then a HFLTS $H(x|c)$ is an ordered finite subset of consecutive linguistic terms of $S$ with $\tau + 1$ linguistic terms; it can be defined as follows:

$$H(x|c) = \{s_{i_1}, s_{i_1+1}, \cdots, s_{i_\tau} \}$$

Recently, Zhu and Xu defined some basic operations of HFLTSs as follows [36]:

**Definition 4.** Ref. [36] Given two HFLTSs: $H_\alpha = \{h_\alpha^1, 1, 2, \cdots, \#H_\alpha\}$ and $H_\beta = \{h_\beta^1, 1, 2, \cdots, \#H_\beta\}$, $H_\alpha = \#H_\beta$, $\lambda \geq 0$, then

$$H_\alpha \uplus H_\beta = \bigcup_{h_\alpha^1 \in H_\alpha, h_\beta^1 \in H_\beta} \{h_\alpha^1 \uplus h_\beta^1\}$$

$$\lambda H_\alpha = \bigcup_{h_\alpha^1 \in H_\alpha} \{\lambda h_\alpha^1\}$$

where $h_\alpha^1$ and $h_\beta^1$ are the $i$th linguistic terms in $H_\alpha$ and $H_\beta$, respectively, and $\#H_\alpha$ and $\#H_\beta$ are the numbers of the linguistic terms in $H_\alpha$ and $H_\beta$, respectively.

Considering the uncertainty of linguistic terms in $H(x|c)$ and the preference of DMs, Pang et al. introduced probability into linguistic terms and then presented the following concept of PLTSs:

**Definition 5.** Ref. [32] Let $S = \{s_\alpha, \alpha = 0, 1, \cdots, \tau\}$ be a LTS; a PLTS is defined as

$$L(p) = \{L^{(k)}(p^{(k)})|L^{(k)} \in S, p^{(k)} \geq 0, k = 1, 2, \cdots, \#L(p), \sum_{k=1}^{\#L(p)} p^{(k)} \leq 1\}$$

where $L^{(k)}(p^{(k)})$ is the linguistic term $L^{(k)}$ associated with the probability $p^{(k)}$ and $\#L(p)$ is the number of all different linguistic terms in $L(p)$.

In particular, when $\sum_{k=1}^{\#L(p)} p^{(k)} = 1$, we have the complete information of probabilistic distribution of all possible linguistic terms, when $\sum_{k=1}^{\#L(p)} p^{(k)} < 1$, partial ignorance exist owing to the limitation of current knowledge. Therefore, we need to normalize the PLTSs.

**Definition 6.** Ref. [32] Given a PLTS $L(p)$ with $\sum_{k=1}^{\#L(p)} p^{(k)} < 1$, the associated PLTS $L(p)$ is defined by

$$L(p) = \{L^{(k)}(p^{(k)})|k = 1, 2, \cdots, \#L(p)\}$$

where $p^{(k)} = \frac{p^{(k)}}{\sum_{k=1}^{\#L(p)} p^{(k)}}$.

**Definition 7.** Ref. [32] Let $L_1(p)$ and $L_2(p)$ be two PLTSs; $\#L_1(p)$ and $\#L_2(p)$ denote the numbers of the linguistic terms in $L_1(p)$ and $L_2(p)$, respectively. If $\#L_1(p) > \#L_2(p)$, in order to make the number of linguistic terms in $L_1(p)$ and $L_2(p)$ be identical, we will add $\#L_1(p) - \#L_2(p)$
linguistic terms to $L_2(p)$. The added linguistic terms are the smallest ones, and their probabilities are zero.

Given two PLTSs, $L_1(p) = \{ L_1^{(k)}(p_1^{(k)}), k = 1, 2, \cdots, \#L_1(p) \}$ and $L_2(p) = \{ L_2^{(k)}(p_2^{(k)}), k = 1, 2, \cdots, \#L_2(p) \}$, the normalization process can be shown by the following steps:

1. If $\sum_{k=1}^{\#L_1(p)} p_1^{(k)} < 1$, then we calculate $L_i(p), i = 1, 2$ by the Definition 6.
2. If $\#L_1(p) \neq \#L_2(p)$, then according to the Definition 7, some elements are added to the one with smaller number of elements.

Simultaneously, Pang et al. defined some basic operations of PLTSs as follows [32]:

**Definition 8.** Ref. [32] Let $L_1(p)$ and $L_2(p)$ be two PLTSs, and $\#L_1(p) = \#L_2(p)$; then, we have the following operation rules:

$$L_1(p) \bigoplus L_2(p) = \bigcup_{L_1^{(k)}(p_1^{(k)}) \in L_1(p), L_2^{(k)}(p_2^{(k)}) \in L_2(p)} \{ L_1^{(k)}(p_1^{(k)}) \bigoplus p_2^{(k)} L_2^{(k)} \}$$  \hspace{1cm} (11)

The following is the other operational law in PLTSs:

$$\lambda L(p) = \bigcup_{L^{(k)}(p^{(k)}) \in L(p)} \lambda p^{(k)} L^{(k)}$$  \hspace{1cm} (12)

### 2.2. Decision-Theoretic Rough Sets

In Decision-theoretic rough sets, $S = \{ C, \neg C \} \triangleq \{ P, N \}$ is supposed to be two states that the object belongs to or belongs to $C$ or $\neg C$ [1,2,37]. In addition, the set of actions is represented by $A = \{ a_P, a_B, a_N \}$, where $a_P$, $a_B$, and $a_N$ indicate three decision actions for classifying an object, which correspond to $x \in POS(C)$, $x \in NEG(C)$, and $x \in BND(C)$ in the decision-making process. The loss function in the actual decision-making process of taking different actions in two states is shown in Table 1, where $\lambda_{PP}$, $\lambda_{BP}$, and $\lambda_{NP}$ denote the losses generated by taking actions $a_P$, $a_B$, and $a_N$, respectively.

### Table 1. Decision cost loss function.

|          | $C(P)$   | $\neg C(N)$ |
|----------|----------|-------------|
| $a_P$    | $\lambda_{PP} = \lambda(a_P|C)$ | $\lambda_{PN} = \lambda(a_P|\neg C)$ |
| $a_B$    | $\lambda_{BP} = \lambda(a_B|C)$ | $\lambda_{BN} = \lambda(a_B|\neg C)$ |
| $a_N$    | $\lambda_{NP} = \lambda(a_N|C)$ | $\lambda_{NN} = \lambda(a_N|\neg C)$ |

Meanwhile, $Pr(C||o||)$ and $Pr(\neg C||o||)$ represent the conditional probability of an object $o$ belonging to $C$ or $\neg C$, and $Pr(C||o||) + Pr(\neg C||o||) = 1$. Therefore, the expected losses for each object $o$ are calculated as

$$R(a_\bullet||o||) = \lambda_{PP} Pr(C||o||) + \lambda_{\bullet N} Pr(\neg C||o||)$$  \hspace{1cm} (13)

For the minimum decision cost, the following decision rules are obtained based on the Bayesian decision procedure:

- **(P)** If $R(a_P||o||) \leq R(a_B||o||)$ and $R(a_B||o||) \leq R(a_N||o||)$, then $o \in POS(C)$.
- **(B)** If $R(a_B||o||) \leq R(a_P||o||)$ and $R(a_P||o||) \leq R(a_N||o||)$, then $o \in BND(C)$.
- **(N)** If $R(a_N||o||) \leq R(a_P||o||)$ and $R(a_P||o||) \leq R(a_B||o||)$, then $o \in NEG(C)$.

The above rules (P)-(N) are called three-way decisions (3WDs), in other words accepted, rejected, and delayed decision [2,38]. Considering the practical applications, a reasonable case of the loss function is often given as $\lambda_{PP} \leq \lambda_{BP} \leq \lambda_{NP}$ and $\lambda_{NN} \leq \lambda_{BN} \leq \lambda_{PN}$.

Thus, the decision rules (P)-(N) can be further simplified as

- **(P1)** If $Pr(C||o||) \geq \alpha$, then $o \in POS(C)$.
- **(B1)** If $\beta < Pr(C||o||) < \alpha$, then $o \in BND(C)$.
- **(N1)** If $Pr(C||o||) \leq \beta$, then $o \in NEG(C)$.
The thresholds are computed by

\[
\alpha = \frac{\lambda_{PN} - \lambda_{BN}}{(\lambda_{PN} - \lambda_{BN}) + (\lambda_{BP} - \lambda_{PP})} \\
\beta = \frac{\lambda_{BN} - \lambda_{NN}}{(\lambda_{BN} - \lambda_{NN}) + (\lambda_{NP} - \lambda_{BP})} \\
\gamma = \frac{\lambda_{PN} - \lambda_{NN}}{(\lambda_{PN} - \lambda_{NN}) + (\lambda_{NP} - \lambda_{BP})}
\]

However, two cases may occur in accordance with the above calculation: (i) \( \alpha > \beta \) and (ii) \( \alpha \leq \beta \). Considering the former first, that is, (i) \( \alpha > \beta \), which means \((\lambda_{BP} - \lambda_{PP})(\lambda_{BN} - \lambda_{NN}) < (\lambda_{PN} - \lambda_{BN})(\lambda_{NP} - \lambda_{BP})\). The rules (P1)-(N1) can be further simplified as

(P2) If \( Pr(C|o|) \geq \alpha \), then \( o \in POS(C) \).
(B2) If \( \beta < Pr(C|o|) < \alpha \), then \( o \in BND(C) \).
(N2) If \( Pr(C|o|) \leq \beta \), then \( o \in NEG(C) \).

(ii) \( \alpha \leq \beta \), which means \((\lambda_{BP} - \lambda_{PP})(\lambda_{BN} - \lambda_{NN}) \geq (\lambda_{PN} - \lambda_{BN})(\lambda_{NP} - \lambda_{BP})\). The rules (P2)-(N2) can be further simplified as

(P3) If \( Pr(C|o|) \geq \gamma \), then \( o \in POS(C) \).
(N3) If \( Pr(C|o|) < \beta \), then \( o \in NEG(C) \).

In order to explain the basic ideals, Figure 1 shows the trisecting-and-acting model in Decision-theoretic rough sets. The triplet (Region 1, Region 2, Region 3) is called a tri-partition of a universal set and a bisection of the set is a special case in it.

![Figure 1. Trisecting-and-acting model.](image-url)
2.3. Equivalent Model of Decision-Theoretic Rough Sets

The conditional probabilities of an object belongs to C or \( \neg C \) are recorded as \( g = Pr(C\text{\mid }o) \) and \( h = Pr(\neg C\text{\mid }o) \), respectively; \( g + h = 1 \). Based on the DTRSs, Liu et al. proposed the following equivalent model [39]:

\[
\alpha^{(opt)}\text{\text{"-model" :}} \\
\alpha^{(opt)} = \min g
\]

\[
\begin{aligned}
&g\lambda_{PP} + h\lambda_{PN} \leq g\lambda_{BP} + h\lambda_{BN} \\
&g + h = 1, h \geq 0
\end{aligned}
\]

(15)

\[
\beta^{(opt)} \text{\text{"-model" :}} \\
\beta^{(opt)} = \max g
\]

\[
\begin{aligned}
&g\lambda_{NP} + h\lambda_{NN} \leq g\lambda_{PP} + h\lambda_{PN} \\
&g + h = 1, h \geq 0
\end{aligned}
\]

(16)

In Equation (15), according to the rules (P) and (P2), the threshold \( \alpha \) is the minimum \( g \) of all conditional probabilities, which satisfies \( R(a_P\mid o) \leq R(a_B\mid o) \) and \( R(a_P\mid o) \leq R(a_N\mid o) \). In Equation (16), according to the rules (N) and (N2), the threshold \( \beta \) is the maximum \( g \) of all conditional probabilities, which satisfies the constraints \( R(a_N\mid o) \leq R(a_P\mid o) \) and \( R(a_N\mid o) \leq R(a_B\mid o) \). Moreover, Liu proved that the equivalent model is mathematically equivalent to the decision-theoretic rough sets.

As the feasibility and validity of the idea have been verified in the literature, we apply the equivalent model in order to solve the evaluation problems of probabilistic linguistics and to obtain the probability threshold and three decision rules in Section 3.

3. Description of Three-Way Decision Problems Based on Evaluation of Probabilistic Linguistic Term Sets

The three-way decision problems based on evaluation of PLTSs is composed of two states \( S = \{C, \neg C\} \triangleq \{P, N\} \) and three actions \( A = \{a_P, a_B, a_N\} \). In addition, the loss function with different actions of decision-making in different states is given with PLTSs. Based on the heuristic knowledge, the value of loss function in multiple objects \( O = \{o_1, o_2, \ldots, o_m\} \) is given by experts with PLTSs, which is shown in Table 2. According to the related data in Table 2, how do we get the thresholds and rules of three-way decisions for each object \( o_i \) (\( i = 1, 2, \ldots, m \))? For each object in Table 2, a proper case of a loss function is as follows: \( L_{BPP} < L_{BPN} < L_{BN} < L_{PB} < L_{PN} \).

Table 2. The loss function matrix of a Probabilistic Linguistic Term (PLT) with multiple objects.

| \( \lambda_{PP} \) | \( \lambda_{PN} \) | \( \lambda_{BP} \) | \( \lambda_{BN} \) | \( \lambda_{NP} \) | \( \lambda_{NN} \) |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| \( o_1 \)       | \( L_{BPP}^1(P) \) | \( L_{BP}^1(P) \) | \( L_{BN}^1(P) \) | \( L_{BN}^1(P) \) | \( L_{BN}^1(P) \) |
| \( o_2 \)       | \( L_{BPP}^2(P) \) | \( L_{BP}^2(P) \) | \( L_{BN}^2(P) \) | \( L_{BN}^2(P) \) | \( L_{BN}^2(P) \) |
| \( \ldots \)    | \( \ldots \)    | \( \ldots \)    | \( \ldots \)    | \( \ldots \)    | \( \ldots \)    |
| \( o_m \)       | \( L_{BPP}^m(P) \) | \( L_{BP}^m(P) \) | \( L_{BN}^m(P) \) | \( L_{BN}^m(P) \) | \( L_{BN}^m(P) \) |

A DTRS model with probabilistic linguistic terms is constructed based on the loss function matrix in Table 2 and its key is the order of PLTSs. Aiming at the problem, the score and deviation degree of PLTSs were put forward.
Definition 9. Ref. [32] Let \( L(p) = \{L^{(k)}(p^{(k)}) | L^{(k)} \in S, k = 1, 2, \cdots, \#L(p)\} \) be a PLTS and \( r_k \) be the subscript of linguistic term \( L^{(k)} \). Then, the score of \( L(p) \) is
\[
E(L(p)) = s_k
\]  
(17)
where \( s_k = \frac{\sum_{k=1}^{\#L(p)} r_k p^{(k)}}{\sum_{k=1}^{\#L(p)} p^{(k)}} \).

Definition 10. Ref. [32] Let \( L(p) = \{L^{(k)}(p^{(k)}) | L^{(k)} \in S, k = 1, 2, \cdots, \#L(p)\} \) be a PLTS and \( r_k \) be the subscript of linguistic term \( L^{(k)} \). Then, the deviation degree of \( L(p) \) is
\[
\sigma(L(p)) = \frac{(\sum_{k=1}^{\#L(p)} (p^{(k)} - \bar{a}))^2 \bar{a}}{\sum_{k=1}^{\#L(p)} p^{(k)}}
\]  
(18)

Definition 11. Ref. [32] For PLTSs \( L_1(p) \) and \( L_2(p) \), \( E(L_1(p)) \) and \( E(L_2(p)) \) are their scores, respectively, and \( \sigma(L_1(p)) \) and \( \sigma(L_2(p)) \) are their deviation degree, respectively. Then, we have the following rules:

1. If \( E(L_1(p)) > E(L_2(p)) \), then \( L_1(p) > L_2(p) \).
2. If \( E(L_1(p)) < E(L_2(p)) \), then \( L_1(p) < L_2(p) \).
3. If \( E(L_1(p)) = E(L_2(p)) \), then \( L_1(p) \approx L_2(p) \).

According to Definition 11, the larger the score function is, the better the corresponding PLTS is, and when the score function is equal, the smaller the deviation function, the better the PLTS is. As \( E(L_1(p)) = E(L_2(p)) \) is rare, we simplify the rules as follows:

1. If \( E(L_1(p)) > E(L_2(p)) \), then \( L_1(p) > L_2(p) \).
2. If \( E(L_1(p)) < E(L_2(p)) \), then \( L_1(p) < L_2(p) \).
3. If \( E(L_1(p)) = E(L_2(p)) \), then \( L_1(p) \approx L_2(p) \).

Therefore, to compare the size of two PLTSs, we just need to calculate and compare the values of their score function.

Based on the basic operations of PLTSs, the loss function of each object \( o_i \) under the action \( a_P, a_B, \) and \( a_N \) and can be recorded as \( \tilde{R}(a_P||o_i) \), \( \tilde{R}(a_B||o_i) \), and \( \tilde{R}(a_N||o_i) \); then,
\[
\tilde{R}(a_\bullet||o_i) = g_iA_{\bullet P} \cup h_iA_{\bullet B} = g_iL_i^{(k)}(P^{(k)}) \cup h_iL_i^{(k)}(B^{(k)})
\]
(19)
\( (\bullet = P, B, N) \).

Obviously, the loss function \( \tilde{R}(a_\bullet||o_i) \) is still a PLTS(s). For the convenience of subsequent discussion, it is recorded as
\[
Q_i^{(k)}(p) = \{Q_i^{(k)}(p^{(k)}) \cup Q_i^{(k)}(p^{(k)}) = g_iL_i^{(k)}(P^{(k)}) \cup h_iL_i^{(k)}(B^{(k)})
\]
(20)
According to Bayesian decision rule for minimum risk, the following rules are obtained:

(P4) If \( \tilde{R}(a_P||o_i) \leq \tilde{R}(a_B||o_i) \) and \( \tilde{R}(a_P||o_i) \leq \tilde{R}(a_N||o_i) \), then \( o \in POS(C) \).

(B4) If \( \tilde{R}(a_B||o_i) \leq \tilde{R}(a_P||o_i) \) and \( \tilde{R}(a_B||o_i) \leq \tilde{R}(a_N||o_i) \), then \( o \in BND(C) \).

(N4) If \( \tilde{R}(a_N||o_i) \leq \tilde{R}(a_P||o_i) \) and \( \tilde{R}(a_N||o_i) \leq \tilde{R}(a_B||o_i) \), then \( o \in NEG(C) \).

From the decision rule (P4)-(N4), the following proposition can be obtained through the ranking method of Definition 11.
Proposition 1. Let \( \tilde{R}(a_{\bullet} | [o_i]) (\bullet = P, B, N) \) be a loss function of each object \( o_i \) under the action \( a_{\bullet} \); then, the score and deviation degree function is noted as

\[
E(\tilde{R}(a_{\bullet} | [o_i])) = E(Q_{\bullet}^i(p)) = s^i \tag{21}
\]

where \( \bar{r} = \frac{\sum_{k=1}^{r} p_k}{\sum_{k=1}^{r} p_k} \).

For the above linear programming problems, we can use particle swarm optimization techniques that are presented in [40] to search their optimal solution and induce the rules of three-way decisions. We first construct the following linear reformulated model:

\[
\tilde{a}_{i}^{(opt)} - \text{model:} \quad \tilde{a}_{i}^{(opt)} = \min g \\
\quad \text{s.t.} \left\{ \begin{array}{l}
g_i + h_i = 1, h_i \geq 0 \\
\frac{\sum_{k=1}^{r} \alpha^i_k(p_k) p_k}{\sum_{k=1}^{r} p_k} \leq \frac{\sum_{k=1}^{r} \tilde{E}_{\bullet}^i_k(p_k) p_k}{\sum_{k=1}^{r} p_k} \\
\frac{\sum_{k=1}^{r} \alpha^i_k(p_k) (1-p_k)}{\sum_{k=1}^{r} p_k} \leq \frac{\sum_{k=1}^{r} \tilde{E}_{\bullet}^i_k(p_k) (1-p_k)}{\sum_{k=1}^{r} p_k} \\
\frac{\sum_{k=1}^{r} \alpha^i_k(p_k) (1-p_k)}{\sum_{k=1}^{r} p_k} \leq \frac{\sum_{k=1}^{r} \tilde{E}_{\bullet}^i_k(p_k) (1-p_k)}{\sum_{k=1}^{r} p_k}
\end{array} \right. \tag{22}
\]

\[
\tilde{\beta}_{i}^{(opt)} - \text{model:} \quad \tilde{\beta}_{i}^{(opt)} = \max g \\
\quad \text{s.t.} \left\{ \begin{array}{l}
g_i + h_i = 1, h_i \geq 0 \\
\frac{\sum_{k=1}^{r} \alpha^i_k(p_k) p_k}{\sum_{k=1}^{r} p_k} \leq \frac{\sum_{k=1}^{r} \tilde{E}_{\bullet}^i_k(p_k) p_k}{\sum_{k=1}^{r} p_k} \\
\frac{\sum_{k=1}^{r} \alpha^i_k(p_k) (1-p_k)}{\sum_{k=1}^{r} p_k} \leq \frac{\sum_{k=1}^{r} \tilde{E}_{\bullet}^i_k(p_k) (1-p_k)}{\sum_{k=1}^{r} p_k} \\
\frac{\sum_{k=1}^{r} \alpha^i_k(p_k) (1-p_k)}{\sum_{k=1}^{r} p_k} \leq \frac{\sum_{k=1}^{r} \tilde{E}_{\bullet}^i_k(p_k) (1-p_k)}{\sum_{k=1}^{r} p_k}
\end{array} \right. \tag{23}
\]

For linear programming problems, we can directly find the optimal solution through the Linprog function in MATLAB[41]. Next, we give the following theorems to ensure the existence and uniqueness of the optimal solution.

Theorem 1. The feasible region of \( \tilde{a}_{i}^{(opt)} - \text{model} \) is \( D \subseteq \{(g_i, h_i)| g_i \geq 0, h_i \leq 1, g_i + h_i = 1\} \), and \( (0,1) \in D \). Obviously, the feasible region is a nonempty closed bounded set. To deal with the linear programming problems, when the feasible region is a closed bounded region or an unbounded region, an optimal solution must be existed. Moreover, through the simplex method, the test number of all nonbasic variables in the optimal form is negative. Then, it can be determined that the linear programming problem has a unique optimal solution. Likewise, a unique optimal solution can also be obtained in \( \tilde{\beta}_{i}^{(opt)} - \text{model} \).

4. Method to Determining the Threshold Pair and Rules of 3WDs Based on the Evaluation of PLTSs

To deal with the evaluation data in Table 2, we propose an optimization based on \( \tilde{a}_{i}^{(opt)} - \text{model} \) and \( \tilde{\beta}_{i}^{(opt)} - \text{model} (i = 1, 2, \ldots, m) \), which can get the rules of three-way decisions directly.

Step 1: Constraining \( \tilde{a}_{i}^{(opt)} - \text{model} \) and \( \tilde{\beta}_{i}^{(opt)} - \text{model} \) through the loss function matrix with multiple objects in Table 2.

Step 2: This step involves calculating the optimal results of \( \tilde{a}_{i}^{(opt)} - \text{model} \) and \( \tilde{\beta}_{i}^{(opt)} - \text{model} (i = 1, 2, \ldots, m) \), and supposing the optimal results \( \tilde{a}_{i}^{opt} \) and \( \tilde{\beta}_{i}^{opt} \).
(i) If $\tilde{\alpha}^{(opt)}_i > \tilde{\beta}^{(opt)}_i$, then DMs adopt the three-way decision model.

(P6) If $Pr(C|o_i) \geq \tilde{\alpha}^{(opt)}_i$, then $o_i \in POS(C)$.

(B6) If $\tilde{\beta}^{(opt)}_i < Pr(C|o_i) < \tilde{\alpha}^{(opt)}_i$, then $o_i \in BND(C)$.

(N6) If $Pr(C|o_i) \leq \tilde{\beta}^{(opt)}_i$, then $o_i \in NEG(C)$.

(ii) If $\tilde{\alpha}^{(opt)}_i = \tilde{\beta}^{(opt)}_i$, then the DMs adopt a two-way decision model.

(P7) If $Pr(C|o_i) \geq \tilde{\alpha}^{(opt)}_i$, then $o_i \in POS(C)$.

(N7) If $Pr(C|o_i) < \tilde{\alpha}^{(opt)}_i$, then $o_i \in NEG(C)$.

Based on the trisecting-and-acting model in Figure 1 and the above steps, a three-way decision model based on PLTS(s) evaluations is proposed in Figure 2.

Based on the above model, the specific algorithm is given below (Algorithm 1).

**Algorithm 1**: An algorithm for deriving three-way decisions based on PLTSs evaluations.

input: the conditional probability $Pr(C|o_i)$ and value of loss function $\lambda^*_{o_i}$ of each object $o_i$ in Table 2, where $\lambda^*_{o_i}$ is given by PLTSs, and $i = 1, 2, \ldots, m, \bullet = P, B, N, o = P, N$.

output: the rules of three-way decisions of object $o_i (i = 1, 2, \ldots, m)$ for $i = 1$ to $m$ do

constricting $\tilde{\alpha}^{(opt)}_i$-model and $\tilde{\beta}^{(opt)}_i$-model ($i = 1, 2, \ldots, m$), and calculate the optimal results $\tilde{\alpha}^{opt}_i$ and $\tilde{\beta}^{opt}_i$.

if $\tilde{\alpha}^{(opt)}_i > \tilde{\beta}^{(opt)}_i$ then

the object $o_i$ adopts three-way decisions model

if $Pr(C|o_i) \geq \tilde{\alpha}^{opt}_i$ then

decision: $o_i \in POS(C)$;

else if $Pr(C|o_i) \leq \tilde{\beta}^{opt}_i$ then

decision: $o_i \in NEG(C)$;

else

decision: $o_i \in BND(C)$;

end

else

the object $o_i$ adopts two-way decisions model

if $Pr(C|o_i) \geq \tilde{\alpha}^{opt}_i$ then

decision: $o_i \in POS(C)$;

else

decision: $o_i \in NEG(C)$;

end

end

end
5. Example Analysis and Comparison Discussion

5.1. Example Analysis

In order to verify the validity of the proposed method, consider three bidding companies that can be divided into good companies and bad companies, depending on the previous experience of project contracting. These parties participate in project bidding simultaneously and the tendering company may take any of the three actions (accept, further consider, or abandon) against the bidding companies. However, the loss function for different types of bidding companies with three different actions is diverse. For example, it may lead to tenderer great economic benefits when choosing to accept a good bidding company. Conversely, it may lead to huge economic losses and time wastage. Therefore, in order to make reasonable scientific decisions in the bidding process, the tendering company hires the relevant experts to conduct a comprehensive evaluation of the bidding project at the beginning period of preparation. According to the prior knowledge, the loss function, which is outlined in Table 3 [33], is given by an expert in the field in the form of probability linguistic terms. Meanwhile, to simplify the problem, the conditional probabilities are constructed based on the equivalent model in Section 2 and the loss function in Table 3, and so do the other companies.

Table 3. The loss function matrix of PLT with multiple objects.

|       | o1 | o2 | o3 |
|-------|----|----|----|
| \( \lambda_{PP} \) | \{ s₁(0.40), s₂(0.45), s₃(0.15) \} | \{ s₁(0.80), s₂(0.10), s₃(0.10) \} | \{ s₁(0.15), s₂(0.25), s₃(0.60) \} |
| \( \lambda_{PN} \) | \{ s₁(0.25), s₂(0.25), s₃(0.50) \} | \{ s₁(0.05), s₂(0.20), s₃(0.75) \} | \{ s₁(0.70), s₂(0.15), s₃(0.15) \} |
| \( \lambda_{BP} \) | \{ s₁(0.30), s₂(0.55), s₃(0.15) \} | \{ s₁(0.70), s₂(0.10), s₃(0.15) \} | \{ s₁(0.15), s₂(0.20), s₃(0.65) \} |
| \( \lambda_{BN} \) | \{ s₁(0.25), s₂(0.35), s₃(0.40) \} | \{ s₁(0.10), s₂(0.25), s₃(0.65) \} | \{ s₁(0.75), s₂(0.15), s₃(0.10) \} |
| \( \lambda_{NP} \) | \{ s₁(0.25), s₂(0.50), s₃(0.25) \} | \{ s₁(0.65), s₂(0.10), s₃(0.25) \} | \{ s₁(0.15), s₂(0.15), s₃(0.70) \} |
| \( \lambda_{NN} \) | \{ s₁(0.35), s₂(0.25), s₃(0.40) \} | \{ s₁(0.10), s₂(0.35), s₃(0.55) \} | \{ s₁(0.80), s₂(0.15), s₃(0.05) \} |

The expected losses for \( o₁ \) with three different actions based on the data in Table 3 and Formula (13):
\[ Q_1^p(p) = \{s_1(0.40g_1 + 0.25h_1), s_2(0.45g_1 + 0.25h_1), s_3(0.15g_1 + 0.50h_1)\} \]

\[ Q_2^p(p) = \{s_1(0.30g_1 + 0.25h_1), s_2(0.55g_1 + 0.35h_1), s_3(0.15g_1 + 0.40h_1)\} \]

\[ Q_3^p(p) = \{s_1(0.25g_1 + 0.35h_1), s_2(0.50g_1 + 0.25h_1), s_3(0.25g_1 + 0.40h_1)\} \]

\[
\tilde{\alpha}_1^{\text{(opt)}} - \text{model}:
\tilde{\alpha}_1^{\text{(opt)}} = \min g_1
\]

\[
\begin{cases}
\begin{array}{l}
g_1 + h_1 = 1, h_1 \geq 0 \\
s.t.
\end{array}
\end{cases}
\]

\[
\begin{align*}
0.4g_1 + 0.25h_1 + (0.45g_1 + 0.25h_1) \times 1 + (0.15g_1 + 0.50h_1) \times 3 & \leq 0.3g_1 + 0.25h_1 + (0.55g_1 + 0.35h_1) \times 2 + (0.15g_1 + 0.40h_1) \times 3 \\
0.4g_1 + 0.25h_1 + (0.45g_1 + 0.25h_1) \times 2 + (0.15g_1 + 0.50h_1) \times 3 & \leq 0.25g_1 + 0.35h_1 + (0.55g_1 + 0.35h_1) \times 2 + (0.25g_1 + 0.40h_1) \times 3
\end{align*}
\]

\[
\begin{align*}
\tilde{\beta}_1^{\text{(opt)}} - \text{model}:
\tilde{\beta}_1^{\text{(opt)}} = \max g_1
\end{align*}
\]

\[
\begin{cases}
\begin{array}{l}
g_1 + h_1 = 1, h_1 \geq 0 \\
s.t.
\end{array}
\end{cases}
\]

\[
\begin{align*}
0.25g_1 + 0.35h_1 + (0.55g_1 + 0.25h_1) \times 2 + (0.25g_1 + 0.4h_1) \times 3 & \leq 0.4g_1 + 0.25h_1 + (0.45g_1 + 0.25h_1) \times 2 + (0.15g_1 + 0.50h_1) \times 3 \\
0.25g_1 + 0.35h_1 + (0.55g_1 + 0.25h_1) \times 2 + (0.15g_1 + 0.40h_1) \times 3 & \leq 0.3g_1 + 0.25h_1 + (0.45g_1 + 0.25h_1) \times 2 + (0.15g_1 + 0.40h_1) \times 3
\end{align*}
\]

Step 2: By calculating the optimal solutions in \(\tilde{\alpha}_1^{\text{(opt)}}\)-model and \(\tilde{\beta}_1^{\text{(opt)}}\)-model the optimal solution and three-way decision rules are derived and given in Table 4.

Table 4 shows that the probability thresholds of three–way decisions about three bidding companies are \(\tilde{\alpha}_1^{\text{opt}} = 0.5\) \(\tilde{\beta}_1^{\text{opt}} = 0.4\) \(\tilde{\alpha}_2^{\text{opt}} = 0.75\) \(\tilde{\beta}_2^{\text{opt}} = 0.2857\) and \(\tilde{\alpha}_3^{\text{opt}} = \tilde{\beta}_3^{\text{opt}} = 0.6667\), respectively. Consequently, the company should accept \(o_1\) and reject \(o_3\) under the condition probability given in Table 4, and \(o_2\) needs further consideration.

Table 4. The probability thresholds and three-way decisions of three companies using the proposed method.

| \(O\) | \(O_1\) | \(O_2\) | \(O_3\) |
|-------|-------|-------|-------|
| \(Pr(C|o_i)\) | 0.7035 | 0.6535 | 0.3545 |
| \(\tilde{\alpha}_i^{\text{opt}}\) | 0.5 | 0.75 | 0.6667 |
| \(\tilde{\beta}_i^{\text{opt}}\) | 0.4 | 0.2857 | 0.6667 |
| Decision mode | three-way decisions | three-way decisions | two-way decisions |
| Decision rules | POS(C) | BND(C) | NEG(C) |

From the analysis results, the method proposed in this paper can be applied to deal with the problem that the loss function is in the form of hesitation fuzzy linguistic terms and probability linguistic terms. We could determine the probability threshold of the three decisions and obtain the relevant decision rules simultaneously.

5.2. Comparison Discussion

Approaches based on the classical DTRSs are here to analyze the example in [2]. According to Formula (13), we calculate the \(R(\hat{u}^\bullet|o_i)\) \((\bullet = P, B, N)\) of the three companies. By the use of Formula (14), the threshold pairs are obtained. Then, we found that the threshold pairs are the same as those generated by our method.

Compared to the approaches, our method has the following advantages.
(1) Our method can determine the thresholds stated herein and overcome the drawback of not capturing these thresholds in various scenarios.

(2) Our method can be used for the determination of the thresholds with the loss function, which are evaluated by other semantics. Therefore, our approach is more universal than others.

6. Conclusions

According to the existing method in some practical situations, evaluating concrete data and determining the probability threshold of the three-way decisions are difficult. This paper studies an optimal model based on the loss function evaluated by PLTSs. Quoting the equivalent model of DTRSs, the optimization models with a loss function of the probabilistic linguistic terms are used to determine the three-way decision threshold. The analysis results of the following examples show that the method proposed in this paper can effectively solve problems that are difficult to determine, such as the probability thresholds of three-way decisions evaluated by fuzzy language. As an extension of the method in this work, we propose that our method can be applied to determine the application of fuzzy set theory in the actual decision environment; it also provides a new idea for the follow-up study of fuzzy language evaluation.

In order to further explore the influence of different ranking methods on decision-making results, we hope to introduce the concepts of both the fuzzy entropy and hesitant entropy of PLTSs in three-way decisions.
