THE GROUND STATE OF A GENERAL ELECTRON-PHONON
HAMILTONIAN IS A SPIN SINGLET

Abstract: The many-body ground state of a very general class of electron-phonon Hamiltonians is proven to contain a spin singlet (for an even number of electrons on a finite lattice). The phonons interact with the electronic system in two different ways—there is an interaction with the local electronic charge and there is a functional dependence of the electronic hopping Hamiltonian on the phonon coordinates. The phonon potential energy may include anharmonic terms, and the electron-phonon couplings and the hopping matrix elements may be nonlinear functions of the phonon coordinates. If the hopping Hamiltonian is assumed to have no phonon coordinate dependence, then the ground state is also shown to be unique, implying that there are no ground-state level crossings, and that the ground-state energy is an analytic function of the parameters in the Hamiltonian. In particular, in a finite system any self-trapping transition is a smooth crossover not accompanied by a nonanalytical change in the ground state. The spin-singlet theorem applies to the Su-Schrieffer-Heeger model and both the spin-singlet and uniqueness theorems apply to the Holstein and attractive Hubbard models as special cases. These results hold in all dimensions — even on a general graph without periodic lattice structure.

I. INTRODUCTION

Electrons have a tendency to pair when the effective electron-electron interaction has an attractive region; in particular this occurs when electrons interact by exchanging bosons. The resulting ground state then often sustains either superconducting or charge-density-wave order. The simplest interacting Hamiltonian of this type is one in which electrons interact indirectly with each other via phonons. Migdal\(^1\) analyzed the electron-phonon interaction in the normal state and discovered that in the limit in which the phonon frequency \(\Omega\) is much smaller than the Fermi energy \(E_f\), the full many-body theory can be described by a first-order, self-consistent Hartree-Fock theory, and that the neglected higher-order diagrams (vertex corrections) usually contribute to order \(\Omega/E_f\). This result has been named Migdal’s theorem and it classifies those nonadiabatic processes that are typically important for describing low-frequency electron-phonon interactions. Soon thereafter, Eliashberg\(^2\) generalized Migdal’s result to the superconducting phase and discovered that a similar first-order self-consistent Hartree-Fock theory would describe superconductivity. Rowell and McMillan\(^3\) subsequently demonstrated that one could directly measure the electron-phonon spectral density from tunneling experiments and then use the formalism of Migdal and Eliashberg to describe all of the remaining properties of the superconducting state. Migdal-Eliashberg theory has been successful in predicting transition temperatures (and other materials properties) of most low temperature superconductors\(^4,5\).

The electron-phonon Hamiltonian considered here is

\[
H = \sum_{\sigma} \sum_{x,y \in \Lambda} t_{xy}(q) c_{x\sigma}^\dagger c_{y\sigma} + \sum_{x \in \Lambda} G_x(q)(n_{x\uparrow} + n_{x\downarrow}) + \frac{1}{2} \sum_{j=1}^\nu (M_j \Omega_j \Omega_j^2 q_j^2 + \frac{1}{M_j} p_j^2) + V_{\text{an}}(q).
\]

We can also add to this an attractive Hubbard type interaction — as discussed later in Sect. III. Our notation is the following: The electrons occupy positions on a finite “lattice” or “graph” \(\Lambda\), which is some collection of \(|\Lambda|\) sites; we emphasize that no specific periodicity or dimensionality is assumed. The operator \(c_{x\sigma}^\dagger\) \((c_{x\sigma})\) is a creation (annihilation) operator for an electron at lattice site \(x\) with \(z\)-component of spin \(\sigma = \uparrow\) or \(\downarrow\). These operators satisfy the anticommutation relations \(c_{x\sigma}^\dagger c_{y\sigma} + c_{y\sigma}^\dagger c_{x\sigma} = \delta_{xy}\) and \(c_{x\sigma} c_{y\sigma} + c_{y\sigma} c_{x\sigma} = 0\) for each \(\sigma = \uparrow\) or \(\downarrow\). It is customary to assume that the up-spin operators also anticommute with the down-spin operators, but it is more convenient for us to assume that they commute,
i.e., \( c_{x \uparrow} c_{y \downarrow} - c_{y \downarrow} c_{x \uparrow} = 0 \), etc. This change is innocuous [as long as particle number is conserved — which it is with the Hamiltonian (1.1)] and is effected by replacing \( c_{x \uparrow} \) by the operator \( \exp[i\pi N_1] c_{x \uparrow} \) with \( N_\sigma := \Sigma_{x \in \Lambda} n_{x \sigma} \) and \( n_{x \sigma} := c_{x \sigma}^\dagger c_{x \sigma} \); the operator \( c_{x \uparrow}^\dagger \) is replaced similarly, but \( c_{x \downarrow} \) and \( c_{x \downarrow}^\dagger \) are unchanged.

The phonon modes are indexed by \( j \) and, for technical simplicity, we assume there are finitely many of them, namely \( \nu \). In some special models, such as the Holstein model, defined in (1.9), there is an association between the phonon modes and the lattice sites, but such an association is neither required nor assumed. The phonon coordinates are \( q_1, \ldots, q_\nu \) and the momenta are \( p_1, \ldots, p_\nu \), denoted collectively by \( \mathbf{q} \) and \( \mathbf{p} \).

The \( p_j \)'s and \( q_j \)'s satisfy the usual commutation relations \([q_j, p_k] = i\delta_{jk}\) and we shall represent these in the usual way as operators on \( L^2(\mathbb{R}^\nu) \), the set of square integrable functions of \( \nu \) variables, by \( p_j = -i d/dq_j \) (with \( \hbar = 1 \)).

The most general positive-definite quadratic form can always be put in the normal mode form, shown in (1.1), in which the numbers \( M_j > 0 \) and \( \Omega_j > 0 \) are, respectively, the masses and frequencies of the corresponding phonon normal modes. For convenience, we explicitly exclude zero frequency modes, which, physically, correspond to center of mass translation. The additional potential term \( V_{an}(\mathbf{q}) \) includes all non-quadratic terms; it is completely arbitrary except for the assumption that it is bounded below, i.e., \( V_{an}(\mathbf{q}) \geq C \) for some number \( C \), and that \( \sum_{\nu=1}^\nu M_j \Omega_j^2 q_j^2 + V_{an}(\mathbf{q}) \) goes to infinity faster than linearly in all directions.

The real hopping matrix \( t(\mathbf{q}) \), whose elements are \( t_{xy}(\mathbf{q}) \), is allowed to be an arbitrary measurable function of the phonon coordinates (but not the momenta). An important assumption is that \( t(\mathbf{q}) \) is real and symmetric for each \( \mathbf{q} \), i.e., \( t_{xy}(\mathbf{q}) = t_{yx}(\mathbf{q}) \). We also assume, for convenience, that \( \text{Tr} |t(\mathbf{q})| \) is finite for every \( \mathbf{q} \). [Here, \( |t(\mathbf{q})| = \sqrt{t(\mathbf{q})^2} \).] We do not make any assumption about the relative signs and magnitudes of the hopping matrix elements. The reality assumption generically precludes the interaction of the electronic orbital motion with magnetic fields.

The electron-phonon coupling \( G_x(\mathbf{q}) \) is also an arbitrary real function of the phonon coordinates that couples the phonons to the total electronic charge at lattice site \( x \). For Theorem 1 (existence of singlet ground states) the only assumption about these couplings
is lower boundedness of the total phonon potential energy, i.e., we assume that the function of \( q \) given by
\[
- \text{Tr} |t(q)| - 2 \sum_{x \in \Lambda} |G_x(q)| + \frac{1}{2} \sum_{j=1}^{\nu} M_j \Omega_j^2 q_j^2 + V_{\text{an}}(q)
\]
is bounded below. Usually, one assumes that \( G_x(q) \) is a linear function of \( q \), but we do not do so.

The total spin is a conserved quantity of the Hamiltonian \( H \) in Eq. (1.1). The spin operators are defined to be the quadratic operators
\[
S^z := \frac{1}{2} \sum_{x \in \Lambda} (n_{x \uparrow} - n_{x \downarrow}), \quad S^+ := (S^-)\dagger := \sum_{x \in \Lambda} c_{x \uparrow}^\dagger c_{x \downarrow}.
\]
They all commute with the Hamiltonian \( H \). The spin operators satisfy an SU(2) algebra, and the total-spin operator is defined to be the corresponding quadratic Casimir operator \((S_{\text{op}})^2 := (S^z)^2 + \frac{1}{2} S^+ S^- + \frac{1}{2} S^- S^+\), with eigenvalues \( S(S + 1) \). In particular, we are interested in the eigenvalues of the total-spin operator for the ground states of \( H \) of the electron-phonon model described in Eq. (1).

Our main result asserts that the ground state of the model in (1.1) has an \( S = 0 \) ground state, and that the ground state is often unique.

**THEOREM 1 (Existence of singlet ground states).** Assume the previously stated conditions on the Hamiltonian \( H \) in (1.1). Assume additionally, that the total number of electrons, \( 2N \), is even. Then among all of the ground states of \( H \) there is at least one ground state with total spin \( S = 0 \).

For Theorem 2 (uniqueness of the ground state) additional assumptions are needed.

(i) The hopping matrix elements \( t_{xy} \) are independent of \( q \). We also assume that \( \Lambda \) is connected, i.e., for each \( x \) and \( y \) in \( \Lambda \) there are sites \( x = x_0, x_1, x_2, \ldots, x_n = y \) such that \( t_{x_i x_{i+1}} \neq 0 \) for all \( 0 \leq i \leq n - 1 \). A bond is said to exist between two sites \( x \) and \( y \) in \( \Lambda \) if \( x \neq y \) and if \( t_{xy} \neq 0 \).

(ii) All the functions of \( q \) appearing in \( H \), i.e., \( G_x(q), V_{\text{an}}(q) \), are differentiable. [Actually, it suffices for them to be locally Hölder continuous with densely defined derivatives.]

(iii) The \( G_x(q) \)'s are independent. By this we mean that for each point \( q \in \mathbb{R}^\nu \) the \( \nu \) simultaneous equations
\[
\sum_{x \in \Lambda} \frac{\partial G_x(q)}{\partial q_j} A_x = 0, \quad j = 1, 2, \ldots, \nu
\]
(1.2)
have no common solution other than $A_x = 0$ for all $x \in \Lambda$. In other words the $(|\Lambda| \times \nu)$ matrix $\partial G_x / \partial q_j$ has rank $|\Lambda|$ for each $q \in \mathbb{R}^\nu$. (Again, it suffices for this to hold only on a dense subset of $\mathbb{R}^\nu$.)

(iv) Every mass, $M_j$, is finite.

These conditions hold in many models, e.g., the Holstein model\(^6\), but conditions (i) and (iii) do not hold in the Su-Schrieffer-Heeger (SSH) model\(^7\).

**THEOREM 2 (Uniqueness of the ground state).** If, (i)-(iv) above are satisfied then the ground state is unique (and hence a nondegenerate spin singlet).

**Remarks.**—(1) Theorem 1 has long been conjectured and is consistent with the intuition that the exchange of a boson leads to electron-electron pairing.

(2) The uniqueness theorem establishes that the many-body ground state of $H$ does not have any level crossings for a finite system, thereby establishing the result that the self-trapping transition from a collection of extended polarons to a collection of localized polarons is a smooth crossover, rather than a transition by breaking of analyticity in any finite system.

The proof of these theorems is based upon spin-reflection positivity and is closely related to the analogous proof for the Hubbard model already presented by one of us\(^8\). A different proof based upon Perron-Frobenius positivity arguments, was given for one-dimensional models\(^9\), but it does not appear to be readily generalizable to the present case.

The SSH model is the special case of (1.1) in which the hopping matrix elements are linear functions of the phonon coordinates and the electron-phonon couplings vanish [$G_x(q) = 0$]. To be more precise consider the original SSH model on a periodic one-dimensional chain\(^7\)

$$H_{SSH} = \sum_{\sigma} \sum_{i=1}^{|\Lambda|} \left( t - \delta t (Q_{i+1} - Q_i) \right) (c_{i+1\sigma}^\dagger c_{i\sigma} + c_{i\sigma}^\dagger c_{i+1\sigma}) + \frac{1}{2} \sum_{i=1}^{|\Lambda|} \left[ \kappa (Q_{i+1} - Q_i)^2 + \frac{1}{M} P_i^2 \right] ,$$

(1.4)

with $Q_i$ ($P_i$) the local phonon coordinate (momentum) at site $i$. Transforming to the normal coordinates

$$q_j := \frac{1}{\sqrt{|\Lambda|}} \sum_{k=1}^{|\Lambda|} Q_j \left[ \cos 2\pi k j \frac{|\Lambda|}{|\Lambda|} \right] \quad \frac{1}{2} |\Lambda| \leq j < |\Lambda|$$

$$\sin 2\pi k j \frac{|\Lambda|}{|\Lambda|} \quad 0 \leq j < \frac{1}{2} |\Lambda|$$

(1.5)
yields the electron-phonon Hamiltonian in the form of Eq. (1.1)

\[ H_{SSH} = \sum_{\sigma} \sum_{i=1}^{|\Lambda|} \left[ t - T_{i+1}(q) \right] (c_{i+1\sigma}^\dagger c_{i\sigma} + c_{i\sigma}^\dagger c_{i+1\sigma}) + \frac{1}{2} \sum_{j=0}^{|\Lambda|-1} \left[ M \Omega_j^2 q_j^2 + \frac{1}{M} p_j^2 \right] , \]

with

\[ T_i(q) = \sum_{j=0}^{\lfloor |\Lambda|/2 \rfloor - 1} (-1)^i q_j \sin \frac{2\pi ij}{|\Lambda|} + \sum_{j=\lfloor |\Lambda|/2 \rfloor}^{\lfloor |\Lambda|/2 \rfloor} (-1)^i q_j \cos \frac{2\pi ij}{|\Lambda|} , \]

and \( \Omega_j^2 = 2\kappa [1 + \cos(2\pi j/|\Lambda|)]/M \). Theorem 1 shows that the SSH model always contains a spin-singlet ground state, but the ground state is not necessarily unique. We are aware of no other rigorous results for the SSH model.

The Holstein model\(^6\) is a special case of (1.1) where there is one (internal) normal mode associated with each lattice site (the index \( j \) is identical to the index \( x \)), the hopping matrix elements have no phonon coordinate dependence, the electron-phonon coupling is linear in the phonon coordinate associated with the lattice site

\[ G_x(q) = g_x q_x \]

and the potential energy is harmonic \([V_{an}(q) = 0]\). The resulting Holstein Hamiltonian is

\[ H_{Hol} = \sum_{\sigma} \sum_{x,y \in \Lambda} t_{xy} c_{x\sigma}^\dagger c_{y\sigma} + \sum_{x \in \Lambda} g_x q_x (n_{x\uparrow} + n_{x\downarrow}) + \frac{1}{2} \sum_{x \in \Lambda} (M_x \Omega_x^2 q_x^2 + \frac{1}{M_x} p_x^2) . \]

The Holstein model has independent couplings if all \( g_x \) are nonzero. The only rigorous result for the Holstein model is that of Löwen\(^10\) for one electron. In this case, it has been shown that the ground state is nondegenerate and analytic if the lattice is bipartite.

In the static limit, where all of the phonon masses become infinite, but the spring constant remains finite

\[ M_x \to \infty \Rightarrow \kappa_x = M_x \Omega_x^2 = \text{finite} \]

the phonon kinetic energy terms \( \sum_x p_x^2 / 2M_x \) do not contribute to the Hamiltonian (1.9). The up- and down-spin electrons become independent and the Holstein model maps onto a Falicov-Kimball model\(^11\) with spin one-half conduction electrons and a continuous static field \( q_x \). Techniques similar to those used in the spinless Falicov-Kimball model\(^12\) may be used to show that the ground state is a commensurate charge-density-wave at half
filling\textsuperscript{13,14}. The static limit of the Holstein model has also been investigated by other methods\textsuperscript{15} and shown to possess insulating bipolaronic charge-density-wave order at large enough coupling. The ground state has also been shown to be nonanalytic in one dimension\textsuperscript{15}.

In the instantaneous limit, where the phonon frequency and electron-phonon coupling become infinite, but their ratio remains finite,

\begin{equation}
 g_x \to \infty \quad , \quad \Omega_x \to \infty \quad , \quad \frac{g_x}{\Omega_x} = \text{finite} \quad ,
\end{equation}

the Holstein model maps onto an attractive Hubbard model\textsuperscript{16}. This mapping is illustrated by completing the square in Eq. (1.9)

\begin{equation}
 H_{\text{Hol}} = \sum_{\sigma} \sum_{x, y \in \Lambda} t_{xy} c_{x\sigma}^\dagger c_{y\sigma} - \frac{1}{2} \sum_{x \in \Lambda} U_x (n_{x\uparrow} + n_{x\downarrow})^2 \\
 + \frac{1}{2} \sum_{x \in \Lambda} (M_x \Omega_x^2 (q_x + \frac{g_x}{M_x \Omega_x^2} (n_{x\uparrow} + n_{x\downarrow}))^2 + \frac{1}{M_x} p_x^2) \quad ,
\end{equation}

with the electron-electron interaction \( U_x \) defined to be

\begin{equation}
 U_x := \frac{g_x^2}{M_x \Omega_x^2} \quad .
\end{equation}

In this instantaneous limit the remaining electron and phonon terms in the Hamiltonian decouple because \( \frac{g_x}{M_x \Omega_x^2} \to 0 \), and one is left with an attractive Hubbard model

\begin{equation}
 H_{\text{Hub}} = \sum_{\sigma} \sum_{x, y \in \Lambda} \tilde{t}_{xy} c_{x\sigma}^\dagger c_{y\sigma} - \sum_{x \in \Lambda} U_x n_{x\uparrow} n_{x\downarrow} + \frac{1}{2} \sum_{x \in \Lambda} (M_x \Omega_x^2 q_x^2 + \frac{1}{M_x} p_x^2) \quad ,
\end{equation}

with

\begin{equation}
 \tilde{t}_{xy} := t_{xy} - \frac{1}{2} U_x \delta_{xy} \quad .
\end{equation}

The attractive Hubbard model is already known to have a unique spin-singlet (\( S = 0 \)) ground state for an even number of electrons on a finite lattice\textsuperscript{8}.

In Section II, the proofs of Theorems 1 and 2 are presented for the Hubbard model in order to clarify the results of Ref. 8 and to define our notation and methodology. Section III contains the proofs of these theorems for the electron-phonon Hamiltonian. A discussion of the results follows in Section IV.

**II. ATTRACTIVE HUBBARD MODEL PROOFS**
Proofs are presented for the results in Ref. 8 in order to clarify the previous work and to define the notation and current methodology. We begin with a proof of Theorem 1. The attractive Hubbard model Hamiltonian is given by the electronic terms in Eq. (1.14) with each $U_x \geq 0$ and the bar dropped from the hopping matrix (the hopping matrix elements have no phonon coordinate dependence here).

**Proof of Theorem 1 for the attractive Hubbard model.**—Both the total spin operator $S^2$ and the $z$-component of spin $S^z$ are conserved quantities of the Hubbard model (1.14) and restriction can be made to the $S^z = 0$ subspace (without loss of generality), because every eigenstate with total-spin $S$ can be rotated into the subspace with $S^z = 0$ without changing its energy. Therefore, we can assume there are $N$ electrons of each spin (up and down).

It is convenient to use first quantized notation. We denote the coordinates of the up-spin electrons with $X$ which really is an $N$-tuple $X = (x_1, x_2, \ldots, x_N)$ where each $x_i \in \Lambda$. Similarly $Y$ denotes the coordinates of the down-spin electrons. Any wave function $\Psi$ is a function of both coordinates $\Psi(X, Y)$ and it is antisymmetric in $\{x_i\}_{i=1}^N$ and antisymmetric in $\{y_i\}_{i=1}^N$. Note that if $\Psi(X, Y)$ is an eigenfunction, then so is $\Psi(Y, X)$ and $\Psi(Y, X)^\ast$. (It is here that the condition that the hopping matrix elements $t_{xy}$ are real is used.) Instead of considering an eigenfunction $\Psi(X, Y)$ it is convenient to consider $\Psi(X, Y) + \Psi(Y, X)^\ast$ and $i[\Psi(X, Y) - \Psi(Y, X)^\ast]$. In other words we can, without loss of generality, assume that our eigenfunction, viewed as a matrix indexed by $X$ and $Y$, is self adjoint (but not necessarily real).

$$\Psi(X, Y) = \Psi(Y, X)^\ast. \quad (2.1)$$

The dimension, $d$, of this matrix $\Psi$ is

$$d = \binom{|\Lambda|}{N}. \quad (2.2)$$

Any self-adjoint matrix can be expanded in terms of its eigenfunctions. Thus,

$$\Psi(X, Y) = \sum_{\alpha=1}^{d} w_{\alpha} \phi_{\alpha}(X) \phi_{\alpha}(Y)^\ast \quad (2.3)$$
where the \( \phi_\alpha \)'s are an orthonormal set of functions (but antisymmetric in their argument \( X \)), and the \( w_\alpha \)'s are real numbers. Our aim is to show that the \( w_\alpha \)'s can all be chosen to be nonnegative. This will conclude the proof because it implies that

\[
\sum_X \psi(X, X) > 0, \tag{2.4}
\]

which implies that \( \psi(X_0, X_0) \) is positive for at least one \( X_0 \). This means that the wave function does not vanish when the up-spin electrons and the down-spin electrons are at precisely the same locations — and this is a singlet state. Thus \( \psi \) has a nonvanishing component in the \( S = 0 \) sector.

To show that the \( w_\alpha \)'s can be taken nonnegative, let us write out the energy using the decomposition of \( \Psi \) in (2.3). One easily computes

\[
\langle \Psi | H | \Psi \rangle = 2 \sum_{\alpha=1}^{d} w_\alpha^2 \langle \phi_\alpha | K | \phi_\alpha \rangle - \sum_{x=1}^{|A|} U_x \sum_{\alpha=1}^{d} \sum_{\beta=1}^{d} w_\alpha w_\beta |\langle \phi_\alpha | L_x | \phi_\beta \rangle|^2 \tag{2.5}
\]

\[
\langle \Psi | \Psi \rangle = \sum_{\alpha=1}^{d} w_\alpha^2 \langle \phi_\alpha | \phi_\alpha \rangle \tag{2.6}
\]

where the \( d \)-dimensional matrices \( K \) and \( L_x \) are defined as follows: \( K \) is the first-quantized version of \( \sum_{xy} t_{xy} c_x^\dagger c_y \) (no spin here) and \( L_x \) is the first-quantized version of \( n_x \). More explicitly, the matrix elements appearing in (2.5) and (2.6) are constructed in the following manner: The inner product between two arbitrary vectors \( \phi_2(X) \) and \( \phi_1(X) \) is

\[
\langle \phi_2 | \phi_1 \rangle = \sum_X \phi_2(X)^* \phi_1(X). \tag{2.7}
\]

The kinetic energy matrix elements satisfy

\[
\langle \phi_2 | K | \phi_1 \rangle = \sum_{xy} t_{xy} \sum_{j=1}^{N} \phi_2(x_1, \ldots, x_j, \ldots, x_N)^* \phi_1(x_1, \ldots, y, \ldots, x_N) \tag{2.8}
\]

where the argument of \( \phi_2 \) agrees with the argument of \( \phi_1 \) everywhere except at the \( j^{th} \) index where the site index is \( x \) for \( \phi_2 \) and \( y \) for \( \phi_1 \). The number operator matrix elements satisfy

\[
\langle \phi_2 | L_x | \phi_1 \rangle = \sum_X \phi_2(X)^* \phi_1(X) \sum_{j=1}^{N} \delta_{x_j, x} \tag{2.9}
\]
For the purpose of Theorem 1, the explicit values of these matrix elements are unimportant. The only thing one has to note about (2.5) and (2.6) is that replacing every $w_\alpha$ by $|w_\alpha|$ cannot increase the energy. The first term in (2.5) and the inner product of (2.6) stay the same, while the second term in (2.5) can only improve (if it changes at all). Thus if $\Psi$, given by (2.3) is a ground state of the Hubbard model then so is $|\Psi|$ which is constructed by replacing $w_\alpha \rightarrow |w_\alpha|$ in (2.3). Note that $|\Psi|(X,Y)$ is not equal to $|\Psi(X,Y)|$ in general, but corresponds to $|\Psi| = \sqrt{\Psi^2}$ in the sense of matrices. Q.E.D.

In order to prove Theorem 2 we first need to establish a lemma and in order to state the lemma a definition is needed. If $X = (x_1, \ldots, x_N)$ we define the operator $\Pi^X$ to be

$$\Pi^X := L_{x_1} L_{x_2} \ldots L_{x_N} \quad (2.10)$$

Since the different $L_{x_i}$'s commute, the ordering of factors in (2.10) is unimportant. In second quantized notation $\Pi^X = n_{x_1} \ldots n_{x_N}$ which shows that $\Pi^X$ is an orthogonal projector, i.e., $\Pi^X = (\Pi^X)^\dagger$ and $(\Pi^X)^2 = \Pi^X$. It is also obvious that $\Pi^X$ is a one-dimensional projector. Furthermore, if $X$ and $X'$ differ only by a permutation then $\Pi^X = \Pi^{X'}$. The matrix elements of $\Pi^X$ [analogous to (2.9)] satisfy

$$\langle \phi_2 | \Pi^X | \phi_1 \rangle = \phi_2(X) \ast \phi_1(X) N! . \quad (2.11)$$

[The $N!$ in (2.11) may appear mysterious, but it is not. The reason is that if $\phi_1$ and $\phi_2$ are normalized vectors concentrated at $X$ and all of its $N!$ permutations and at no other $X$, then $|\phi_1(X)|^2 = |\phi_2(X)|^2 = 1/N!$. Thus, both sides of Eq.(2.11) are equal in magnitude to 1.]

**Lemma (Connectivity of the single-spin configuration space).** Assume that the lattice $\Lambda$ is connected as explained above. Then the single-spin configuration space is connected by the kinetic energy matrix $K$. That is to say, given points $X = (x_1, \ldots, x_N), Y = (y_1, \ldots, y_N)$ in the single-spin configuration space, there exists a chain of $m$ points $\{ Y = X_m, X_{m-1}, \ldots, X_2, X_1 = X \}$ in the configuration space, such that the product of matrix elements satisfies

$$\Pi^{X_m} K \Pi^{X_{m-1}} \ldots \Pi^{X_3} K \Pi^{X_2} K \Pi^{X_1} \neq 0 , \quad (2.12)$$

with $X_1 \neq X_2 \neq X_3 \neq \ldots \neq X_m$. 

10
Proof: We first consider a geometric question. Place \(N\) unlabelled markers on the points \((x_1, \ldots, x_N)\) of \(\Lambda\). The goal is to move these markers, one at a time, across bonds of the lattice \(\Lambda\) to a final set of points \((y_1, \ldots, y_N)\) in such a way that at no step is there ever a doubly occupied site of the lattice. We want to emphasize that it is not necessary that the marker that was first at \(x_1\) ends up at \(y_1\), we require only that in the final configuration the sites \((y_1, \ldots, y_N)\) are occupied by some marker.

To do this we apply the following algorithm repeatedly — at most \(N\) times. Look for the smallest \(i\) such that the site \(y_i\) is unoccupied. Look for the smallest \(j\) such the site \(x_j\) is not in the set \(\{y_1, \ldots y_N\}\). We will move a marker from the point \(x_j\) and establish a marker at the point \(y_i\) in such a way that the other occupied sites of the final state are identical to the other occupied sites of the initial state. (Once again, we point out that the marker originally at \(x_j\) need not end up at \(y_i\), and the other markers may be moved in this process.) To achieve this we choose a connected path \(P\) in the lattice \(\Lambda\), \(P = (x_j = z_1, z_2, \ldots z_k = y_i)\) from site \(x_j\) to \(y_i\). Such a path exists by hypothesis. If there are no markers on the sites \(z_2, \ldots, z_{k-1}\), then we simply move the marker at \(x_j\) along the path \(P\) to \(y_i\). Suppose on the contrary, that there are some other markers on this path \(P\). Let \(l\) be the largest number such that \(z_l\) has a marker on it. Then simply move this marker along the path to the site \(y_i\), thereby achieving two things: a marker on \(y_i\) and one less marker along the path \(P\). We then move in turn each marker on the path \(P\) to the location of the previously moved marker. This completes the description of the algorithm and answers the geometric question.

To prove the lemma itself, we first note that \(\langle \phi_2 | \Pi^{X_1} K \Pi^{X_2} | \phi_1 \rangle = 0\) for all \(X_1\) and \(X_2\) unless there is a permutation of \(X_1\) such that after the permutation there exists some \(1 \leq j \leq N\) such that \(x^1_i = x^2_i\) for all \(i \neq j\). In this case

\[
\langle \phi_2 | \Pi^{X_1} K \Pi^{X_2} | \phi_1 \rangle = t_{ab} \phi_2(X_1)^* \phi_1(X_2) N!
\]

where \(x^1_j = a\) and \(x^2_j = b\).

The configurations \(X_1, X_2, \ldots X_m\) used in Eq. (2.12) will be the \(X\)'s determined by the sequence of moves in the geometric discussion above. (Note that although the markers were indistinguishable there we can, if we wish, put numbers on them. In general the final state in this case will not be identically the state \(Y = (y_1, \ldots y_N)\) but will be some
permutation $\tilde{Y}$ of the final state. On the other hand $\Pi^Y = \Pi^\tilde{Y}$ because the $L_x$’s commute.) What remains to be shown is that the operator

$$\Pi^{X_m} K \Pi^{X_{m-1}} \ldots \Pi^{X_2} K \Pi^{X_1} = (\Pi^{X_m} K \Pi^{X_{m-1}})(\Pi^{X_{m-1}} K \Pi^{X_{m-2}}) \ldots (\Pi^{X_2} K \Pi^{X_1}) \quad (2.14)$$

is nonvanishing. Let $\phi_1, \ldots, \phi_d$ be the orthonormal basis proportional to antisymmetrized delta-functions in the configuration space. From (2.13) we see that when we expand (2.14) in these intermediate states, that a factor such as $\langle \phi_i | \Pi^{X_k} K \Pi^{X_{k-1}} | \phi_j \rangle$ can be nonzero for only one $i$ and $j$, and this contribution is equal to $t_{ab}$ (up to an overall sign) where $a$ and $b$ denote the two indices where $X_k$ and $X_{k-1}$ differ. So, in short, there will be exactly one matrix element of $\langle \phi_i | \Pi^{X_m} K \Pi^{X_{m-1}} \ldots \Pi^{X_2} K \Pi^{X_1} | \phi_j \rangle$, and it will be a product of $t_{xy}$’s all of which are nonzero. Q.E.D.

We turn now to the proof of Theorem 2 for the Hubbard model. The four assumptions (i)-(iv) for the electron-phonon model simplify to the two assumptions: (a) $\Lambda$ is connected; (b) every $U_x$ is positive ($U_x > 0$).

**Proof of Theorem 2 for the Hubbard model.** Suppose $\Psi_1$ and $\Psi_2$ are orthogonal ground states. We can assume both $\Psi_1$ and $\Psi_2$ are Hermitian. Then $\Psi = \Psi_1 + \lambda \Psi_2$ is a ground state for all real $\lambda$. Moreover $\Psi$, if viewed as a matrix, cannot be either positive or negative semidefinite for all real $\lambda$. Hence for some choice of $\lambda$ we have that the two ground states $\Psi_\pm := \frac{1}{2}(|\Psi| \pm \Psi)$, are both nonzero, and are both ground states, since $|\Psi|$ is a ground state from Theorem 1. In particular $\Psi_+$ satisfies the matrix Schrödinger equation

$$K \Psi_+ + \Psi_+ K - \sum_{x=1}^{\mid\Lambda\mid} U_x L_x \Psi_+ L_x = e \Psi_+, \quad (2.15)$$

and is a positive semidefinite matrix.

We define $\mathcal{H}_+$ to be the range of the matrix $\Psi_+$, which is a subspace of $\mathcal{H} = \mathbb{C}^d$. We also define $\mathcal{H}_\perp$ to be the orthogonal component of $\mathcal{H}_+$ and $\Pi_\perp$ to be the projector onto $\mathcal{H}_\perp$. By assumption $\mathcal{H}_+$ and $\mathcal{H}_\perp$ are both nontrivial.

Multiply the Schrödinger equation (2.15) on the left and on the right by $\Pi_\perp$ to yield

$$\sum_x U_x \Pi_\perp L_x \Psi_+ L_x \Pi_\perp = 0$$

since $\Pi_\perp \Psi_+ = \Psi_+ \Pi_\perp = 0$. This implies further that

$$\Psi_+ L_x \Pi_\perp = 0 \quad (2.16)$$
since every $U_x$ is positive and $\Psi_+$ is a positive semidefinite matrix. Eq. (2.16) implies that the matrix $L_x$ does not connect the subspaces $\mathcal{H}_+$ and $\mathcal{H}_\perp$. Now multiply (2.15) on the right by $\Pi_\perp$ and use (2.16) to discover that

$$
\Psi_+ K \Pi_\perp = 0. 
$$

(2.17)

Both (2.16) and (2.17) show that $\mathcal{H}_+$ and $\mathcal{H}_\perp$ are invariant subspaces of the matrices $K$ and $L_x$.

We will now use the lemma to show that $\mathcal{H}_\perp$ is trivial, thereby establishing a contradiction. The operators $\Pi^X$ defined in (2.10) are one-dimensional projectors in $\mathcal{H}$ and satisfy

$$
(N!)^{-1} \sum_X \Pi^X = 1.
$$

(2.18)

Thus $V^+ = \Pi^X \Psi^+$ is nonzero for some $X$. Likewise, if $\phi \in \mathcal{H}_\perp$ then $V^\perp = \Pi^Y \phi \neq 0$ for some $Y$. By the lemma, the rank one operator in (2.12), call it $A$, is nonzero and satisfies $(V^\perp, AV^+)$ \neq 0. This is a contradiction since $A$, being a product of $L_x$’s and $K$, has $\mathcal{H}_+$ as an invariant subspace. Q.E.D.

### III. ELECTRON-PHONON MODEL PROOFS

The proof of Theorem 1 employs the same methods as utilized for the Hubbard model in the preceding section, but now all of the expansion coefficients and basis functions have an implicit $q$ dependence. The variational principle that shows that the ground state includes a spin-singlet state will arise from the kinetic energy terms for the phonons, since there is no direct electron-electron interaction here (however, see the remark at the end of the proof of Theorem 2 about including attractive electron-electron interactions).

**Proof of Theorem 1 for the electron-phonon model.** Any wavefunction $\Psi(q)$ can be thought of as a matrix-valued function of $q \in \mathbb{R}^\nu$. By $SU(2)$ invariance of (1.1) we can, as in the preceding proof, assume that there are equal numbers of up-spin and down-spin electrons, namely $N$ of each kind. The dimension $d$ of the matrix $\Psi(q)$ is then

$$
d = \binom{|A|}{N}.
$$

(3.1)

As before, by taking transposes and complex conjugates, we can restrict our discussion to the case where $\Psi(q)$ is a Hermitian matrix for all $q$ (it is here that we use the condition
that the hopping matrix elements $t_{xy}$ are real because, without this condition, the complex
conjugate of $\Psi$ will generally have a different energy from that of $\Psi$). Note that $\Psi(q)$ is
Hermitian, but it need not be real.

We can write the Schrödinger equation for $\Psi$ in the following generic way

$$
- \sum_{j=1}^{\nu} \frac{1}{2M_j} \frac{\partial^2}{\partial q_j^2} \Psi(q) + V(q) \Psi(q) + \Psi(q)V(q) = e\Psi(q).
$$

(3.2)

This equation is to be understood in the following sense: $\Psi(q)$ is a matrix-valued function and so are its second derivatives; $V(q)$ is also a matrix-valued function which is self-adjoint for every $q$; the two terms $V\Psi + \Psi V$ (with matrix multiplication being understood) include all of the terms in $H$ besides the phonon kinetic energy, $\sum_{j=1}^{\nu} p_j^2/2M_j$; of course $e$ is the energy eigenvalue.

Associated with (3.2) is a variational expression which we can write as $\mathcal{E}(\Psi)/\langle \Psi | \Psi \rangle$.

The denominator has the form

$$
\langle \Psi | \Psi \rangle = \int_{\mathbb{R}^\nu} \text{Tr} \Psi(q)^2 dq.
$$

(3.3)

The numerator is

$$
\mathcal{E}(\Psi) = \int_{\mathbb{R}^\nu} \left\{ \sum_{j=1}^{\nu} \frac{1}{2M_j} \text{Tr}[\partial_j \Psi(q)]^2 + 2\text{Tr}V(q)\Psi(q)^2 \right\} dq,
$$

(3.4)

where $\partial_j$ denotes the partial derivative $\partial/\partial q_j$.

Our strategy is to replace the matrix $\Psi(q)$, for every $q$, by its absolute value in the matrix sense, i.e.,

$$
|\Psi(q)| = \sqrt{\Psi(q)^2}.
$$

(3.5)

We note that the norm satisfies $\langle \Psi | \Psi \rangle = |\langle \Psi | \Psi \rangle|$, and that the $V\Psi^2$ term is evidently unchanged. In the appendix we prove that this substitution does not increase the integral of $\text{Tr}[\partial_j \Psi(q)]^2$. There are some nontrivial technical issues here caused by the fact that $\partial_j \Psi(q)$ and $\partial_j |\Psi(q)|$ may only be distributional derivatives, but these issues are fully resolved in the appendix.

Since, by definition of the ground-state energy, $\mathcal{E}(\Psi)$ cannot decrease when $\Psi$ is replaced by $|\Psi|$, we conclude that $|\Psi|$ is also a ground state of the Hamiltonian. As in the
Hubbard model proof, we conclude that $|\Psi(q)|$ has a nonzero projection onto the $S = 0$ subspace, i.e., if every diagonal element of the matrix $|\Psi(q)|$ vanished for almost every value of $q$, $|\Psi(q)|$ would be the zero function, which it is not. Q.E.D.

**Proof of Theorem 2 for the electron-phonon model.** Suppose there are two ground states $\Psi_1(q)$ and $\Psi_2(q)$ which are Hermitian and linearly independent. Then $\Psi_1 + \lambda \Psi_2$ is a nonzero ground state for every real $\lambda$, and as $\lambda$ is varied from $-\infty$ to $+\infty$ there will be values of $\lambda$ for which $\Psi = \Psi_1 + \lambda \Psi_2$ has both a negative and positive spectrum for a set of $q$'s of positive measure. Then $|\Psi|$ is also a ground state, as are $\Psi_+ := \frac{1}{2} (|\Psi|+\Psi)$ and $\Psi_- := \frac{1}{2} (|\Psi|-\Psi)$. Note that $\Psi, |\Psi|, \Psi_+$ and $\Psi_-$ are all nonzero functions that satisfy the Schrödinger equation (3.2). Indeed $\Psi = \Psi_+ - \Psi_-$. Moreover, both $\Psi_+(q)$ and $\Psi_-(q)$ are positive semidefinite matrices for all values of $q$. From the fact that the matrix valued function $V(q)$ appearing in (3.2) is differentiable, elliptic regularity theory applied to the Schrödinger equation tells us that $\Psi(q)$ is twice continuously differentiable [actually only Hölder continuity of $V(q)$ suffices for this conclusion].

At each point $q$, the vector space $C^d$, on which $\Psi(q)$ operates, is naturally the direct sum of three subspaces (some of which might be empty). These subspaces are denoted by $H_+(q), H_-(q)$, and $H_0(q)$. $H_+(q)$ is the spectral subspace of $\Psi_+(q)$, i.e. consists of all linear combinations of the nonzero eigenvectors of $\Psi_+(q)$; $H_-(q)$ is the spectral subspace of $\Psi_-(q)$; and $H_0(q)$ is the orthogonal complement of $H_+(q) \oplus H_-(q)$, i.e., the subspace of all linear combinations of the zero eigenvectors of $\Psi_+(q)$ and $\Psi_-(q)$. Of course $C^d = H_+(q) \oplus H_0(q) \oplus H_-(q)$.

Let $d_0(q)$ denote the dimension of $H_0(q)$ and let $d_0$ denote the minimum of $\{d_0(q) : q \in \mathbb{R}^\nu\}$. Since there are only finitely many values for $d_0(q)$ there is a point $q_0 \in \mathbb{R}^\nu$ for which $d_0(q_0) = d_0$. By definition the matrix $\Psi(q_0)$ has $d_0$ zero eigenvalues, and the positive eigenvalues are separated from zero by a gap $\Delta$. Since $\Psi$, and hence the eigenvalues of $\Psi$, are continuous, there is some ball $B'$ centered at $q_0$ with radius $r$ such that the dimension of $d_0(q) \leq d_0$ for every $q \in B'$. Since, however $d_0$ is the minimum of $d_0(q)$, we conclude that $d_0(q) = d_0$ for every $q \in B'$.

Now let us study the contour integral

$$
\Pi_\perp(q) := \frac{1}{2\pi i} \int_\Gamma \frac{1}{\Psi(q) - z} \, dz \tag{3.6}
$$
where the contour $\Gamma$ runs from $-\infty$ just below the negative real axis, goes vertically upward when the real part of $z = \Delta/2$ and returns to $-\infty$ just above the negative real axis.

First we observe that $\Pi_\perp(q_0)$ is the projector onto the orthogonal complement of $\mathcal{H}_+(q_0)$, namely onto $\mathcal{H}_\perp(q_0) = \mathcal{H}_0(q_0) \oplus \mathcal{H}_-(q_0)$. Furthermore, the zero eigenvalues of $\Psi_+(q)$ do not move from zero as long as $q \in B'$, as we have just seen above. Therefore, $\Pi_\perp(q)$ continues to be the projector onto $\mathcal{H}_\perp(q)$ as long as the positive eigenvalues of $\Psi(q)$ are greater than $\Delta/2$, and hence do not intersect the contour $\Gamma$. Since $\Psi$ is continuous we conclude there is a smaller ball $B \subset B'$ centered at $q$ in which $\Pi_\perp(q)$ continues to be the projector onto $\mathcal{H}_\perp(q)$. Since $\Psi(q)$ is twice continuously differentiable, it is a trivial matter to show that we can differentiate under the integral sign in (3.6) and conclude that $\Pi_\perp(q)$ is a twice continuously differentiable matrix-valued function on $B$.

Now we compute some derivatives in this ball $B$. We start with the observation that $\Psi_+(q) \Pi_\perp(q) = 0$ for all $q$ in $\mathbb{R}^\nu$. The following identities hold in $B$: (we suppress the $q$ dependence):

$$
(\partial_j \Psi_+) \Pi_\perp + \Psi_+ \partial_j \Pi_\perp = 0 \quad (3.7)
$$

$$
(\partial^2_j \Psi_+) \Pi_\perp + 2(\partial_j \Psi_+) \partial_j \Pi_\perp + \Psi_+ \partial^2_j \Pi_\perp = 0. \quad (3.8)
$$

If the Schrödinger equation (3.2) for $\Psi_+(q)$ is multiplied on the left and on the right by $\Pi_\perp(q)$ we have (since $\Psi_+ \Pi_\perp = 0 = \Pi_\perp \Psi_+$)

$$
\sum_{j=1}^\nu \frac{1}{2M_j} \Pi_\perp (\partial^2_j \Psi_+) \Pi_\perp = 0, \quad (3.9)
$$

or, combining (3.9) with (3.8) we discover that

$$
\sum_{j=1}^\nu \frac{1}{2M_j} \Pi_\perp (\partial_j \Psi_+) \partial_j \Pi_\perp = 0. \quad (3.10)
$$

Now multiply (3.7) on the left by $\partial_j \Pi_\perp/2M_j$ and sum over $j$. The first term vanishes because of the adjoint of (3.10). The second yields

$$
\sum_{j=1}^\nu \frac{1}{2M_j} \partial_j \Pi_\perp \Psi_+ \partial_j \Pi_\perp = 0. \quad (3.11)
$$
Since $\Psi_+(q)$ is a positive semidefinite matrix (and all $M_j < \infty$), we conclude from (3.11) that

$$\Psi_+ \partial_j \Pi_\perp = 0, \quad j = 1, \ldots, \nu$$  \hspace{1cm} (3.12)

for all $q \in B$. Eq. (3.12) states that the range of the derivatives of $\Pi_\perp$ lies in $\mathcal{H}_\perp$, or

$$\partial_j \Pi_\perp = \Pi_\perp \partial_j \Pi_\perp,$$  \hspace{1cm} (3.13)

and therefore that each term in (3.7) separately vanishes, i.e.,

$$(\partial_j \Psi_+) \Pi_\perp = 0.$$  \hspace{1cm} (3.14)

Differentiating (3.14) yields

$$(\partial^2_j \Psi_+) \Pi_\perp + (\partial_j \Psi_+) \partial_j \Pi_\perp = 0.$$  \hspace{1cm} (3.15)

But $(\partial_j \Psi_+) \partial_j \Pi_\perp = (\partial_j \Psi_+) \Pi_\perp \partial_j \Pi_\perp = 0$ from (3.13) and (3.14), so we finally conclude that the range of the second derivative of $\Psi_+$ lies in $\mathcal{H}_+$, or

$$(\partial^2_j \Psi_+) \Pi_\perp = 0$$  \hspace{1cm} (3.16)

for all $q \in B$.

If we multiply the Schrödinger equation (3.2) for $\Psi_+$ on the right by $\Pi_\perp$ and use the identity (3.16) we find

$$\Psi_+(q) \left[ K(q) + \sum_{x=1}^{\lvert \Lambda \rvert} L_x G_x(q) \right] \Pi_\perp(q) = 0.$$  \hspace{1cm} (3.17)

This says that the matrix $W(q) := K(q) + \sum_{x=1}^{\lvert \Lambda \rvert} L_x G_x(q)$ does not connect $\mathcal{H}_+$ with $\mathcal{H}_\perp$. Differentiating (3.17) shows that

$$(\partial_j \Psi_+) W \Pi_\perp + \Psi_+ (\partial_j W) \Pi_\perp + \Psi_+ W \partial_j \Pi_\perp = 0.$$  \hspace{1cm} (3.18)

But we know that the range of the derivatives of $\Psi_+$ lies in $\mathcal{H}_+$ and that of the derivatives of $\Pi_\perp$ lies in $\mathcal{H}_\perp$, so the first and last terms of (3.18) vanish because $W$ does not connect $\mathcal{H}_+$ with $\mathcal{H}_\perp$. Since the hopping matrix elements do not have any $q$ dependence by assumption
and the derivative of the electron-phonon couplings is a rank $|\Lambda|$ matrix by assumption, we find

$$\Psi_+ L_x \Pi_\perp = 0 \quad x = 1, \ldots, |\Lambda|$$  \hspace{1cm} (3.19)

and, from (3.17),

$$\Psi_+ K \Pi_\perp = 0.$$  \hspace{1cm} (3.20)

These two identities imply that both $\mathcal{H}_+ (\mathbf{q})$ and $\mathcal{H}_\perp (\mathbf{q})$ are invariant subspaces of the matrices $K$ and $L_x$ for all $\mathbf{q} \in \mathcal{B}$. Exactly as in the Hubbard model proof, we conclude that for every $\mathbf{q} \in \mathcal{B}$ one of the two alternatives holds: either $\mathcal{H}_+ (\mathbf{q}) = \{0\}$ or $\mathcal{H}_\perp (\mathbf{q}) = \{0\}$. Since the functions $\Psi_+$ and $\Psi_-$ are continuous, the set on which $\Psi_+$ is nonzero is open and the set on which $\Psi_-$ is nonzero is open. Therefore $\mathcal{B}$ contains an open set in which either $\Psi_+ (\mathbf{q})$ is identically zero or $\Psi_- (\mathbf{q})$ is identically zero. However this cannot happen since $\Psi_+$ and $\Psi_-$ are eigenfunctions with locally bounded potentials $V (\mathbf{q})$ and therefore satisfy a unique continuation theorem. That is to say if $\Psi_+$ vanishes in some open set, it vanishes in all of $\mathbb{R}^\nu$ contrary to our original assumption that $\Psi_+$ is not identically zero. Q.E.D.

Remarks.—(1) Both Theorems 1 and 2 continue to be valid if any attractive Hubbard model terms are added to the Hamiltonian in (1.1). In other words, the electron-phonon model and Hubbard model results do not interfere with each other as long as they are attractive.

(2) The SSH model is shown here to have at least one spin-singlet state among its ground states. The ground state is not shown to be unique here. The difficulty for the uniqueness proof enters in the derivative of the matrix $W$ in Eq. (3.18).

IV. DISCUSSION

The results presented in this contribution hold only for an even number of electrons in a finite system. In this case, the only nonanalyticities that can enter in properties of the ground state occur when there is a ground-state level crossing. In the cases where the ground state can be shown to be unique, there are never any level crossings, so that any “transition” of the electron-phonon ground state from a collection of delocalized polarons to a collection of self-trapped polarons is not a sharp transition, but is a smooth crossover. We are not prepared to prove any statements about the thermodynamic limit here.
One can ask if these results will survive if a magnetic field is turned on. The answer in general is no because the variational argument presented in Theorem 1 no longer holds if there are interactions with the local electronic spin [as one would have if one added a Zeeman coupling to the Hamiltonian in Eq. (1.1)]. One can also investigate the effect of a magnetic field on the electronic kinetic energy. The hopping matrix elements are always assumed to be real, and therefore can only incorporate flux phases that correspond to entrapped fluxes that are integral multiples of $\pi$. If the hopping matrix elements become complex, the entire methodology incorporated here fails, and there are no rigorous statements that we can make about this case.

In conclusion, we have presented a proof that the ground state of a general class of electron-phonon Hamiltonians must include a state that is a spin singlet. The phonons can interact with the electrons in two different ways—the phonons interact with the local electronic charge and the phonons modulate the electronic hopping integrals. The phonon coordinate dependence of the both electron-phonon couplings and the hopping matrix elements is arbitrary. The phonons can be optical modes or acoustical modes, and can contain anharmonic couplings. The hopping matrix is always assumed to be real and symmetric. The Su-Schrieffer-Heeger model, the Holstein model, and the Hubbard model all fall into this general class. In the case where the hopping matrix contains no phonon coordinate dependence, the lattice is connected, the electron-phonon couplings are independent, and the inverse phonon masses are all positive, the ground state has also been shown to be unique.

Acknowledgments

We are indebted to Jan Philip Solovej for valuable discussions, especially for his help with the appendix. This work was supported by the U. S. National Science Foundation under grant no. PHY90-19433 A03 [EHL], and by the Office of Naval Research under grant no. N00014-93-1-0495 [JKF].
APPENDIX: ABSOLUTE VALUE DECREASES KINETIC ENERGY

We shall prove here that replacing a matrix-valued function, $\Psi(q)$ by its absolute value, $|\Psi(q)| = \sqrt{\Psi^\dagger(q)\Psi(q)}$, decreases each component of the kinetic energy

$$T_j(\Psi) := \int_{\mathbb{R}^n} \text{Tr}\left[\partial_j \Psi^\dagger(q) \partial_j \Psi(q)\right] dq,$$

(A.1)

when $\Psi$ is Hermitian. (Here $\partial_j = \partial/\partial q_j$ and $\dagger$ denotes adjoint.)

Before going into the technicalities, let us give a heuristic discussion to motivate the truth of our assertion. If we write, in Dirac notation,

$$\Psi(q) = \sum_{\alpha=1}^d w_{\alpha}(q)|f_{\alpha}(q)\rangle\langle f_{\alpha}(q)|,$$

(A.2)

where $d$ is the dimension of the matrix (in our proof later we shall generalize to $d = \infty$), the functions $w_{\alpha}$ are the real eigenvalues and the $|f_{\alpha}(q)\rangle$ are the $q$-dependent orthonormal eigenfunctions of the Hermitian matrix $\Psi(q)$. Supposing everything to be differentiable we can compute

$$\partial_j \Psi(q) = \sum_{\alpha=1}^d \partial_j w_{\alpha}(q)|f_{\alpha}(q)\rangle\langle f_{\alpha}(q)| + w_{\alpha}(q)|f_{\alpha}(q)\rangle\langle g_{\alpha}(q)| + w_{\alpha}(q)|g_{\alpha}(q)\rangle\langle f_{\alpha}(q)|,$$

(A.3)

where $|g_{\alpha}(q)\rangle = \partial_j |f_{\alpha}(q)\rangle$. Since $\langle f_{\alpha}(q)|f_{\beta}(q)\rangle = \delta_{\alpha\beta}$, we have that $\langle f_{\alpha}(q)|g_{\beta}(q)\rangle + \langle g_{\alpha}(q)|f_{\beta}(q)\rangle = 0$. Thus, if we square (A.3) and take the trace we have

$$\text{Tr}[\partial_j \Psi(q)]^2 = \sum_{\alpha=1}^d [\partial_j w_{\alpha}(q)]^2 + 2w_{\alpha}(q)|g_{\alpha}(q)|^2 - 2\sum_{\alpha=1}^d \sum_{\beta=1}^d w_{\alpha}(q)w_{\beta}(q)|g_{\alpha}(q)|^2.$$

(A.4)

From this we see that replacing $w_{\alpha}(q)$ by $|w_{\alpha}(q)|$ can only decrease the last term on the right. The second term does not change. The first term also does not change since, for any real, differentiable function $w(q)$, it is a fact that $[\partial_j w(q)]^2 = [\partial_j |w(q)|]^2$ in the sense of distributions.

Notice that this heuristic discussion gives a pointwise inequality $\text{Tr}[\partial_j \Psi(q)]^2 \geq \text{Tr}[\partial_j |\Psi(q)|]^2$.

In our rigorous discussion we shall content ourselves with an inequality for the integral (A.1) — which is sufficient for our purposes in this paper.
We begin the rigorous discussion with some definitions. Let \( \mathcal{H} \) be a fixed, separable Hilbert space (for the purposes of our paper \( \mathcal{H} \) is finite dimensional, but there is no need for this restriction here). Let \( \mathcal{B} \) denote the Hilbert-Schmidt operators on \( \mathcal{H} \) and, for \( A \in \mathcal{B} \), let
\[
\|A\| := \{\text{Tr}A^\dagger A\}^{1/2}
\]
denote its *Hilbert-Schmidt norm*. We also define
\[
|A| := \sqrt{A^\dagger A} \quad \text{and} \quad |A^\dagger| := \sqrt{AA^\dagger}
\]
and note that \( \|A\| = \|A^\dagger\| = \|A\| \).

A map
\[\Psi : \mathbb{R}^\nu \to \mathcal{B}\]
is said to be *measurable* if the function \( f_A(q) := \|\Psi(q) - A\| \) is (Lebesgue) measurable for every Hilbert-Schmidt \( A \). It is not hard to prove that \( \Psi \) is measurable if and only if every matrix element \( (v, \Psi(q)w) \) is a measurable function for every fixed \( v \) and \( w \) in \( \mathcal{H} \). \( \Psi \) is said to be in \( L^2(\mathbb{R}^\nu; \mathcal{B}) \) if \( \Psi \) is measurable and if \( f_0 \in L^2(\mathbb{R}^\nu) \), i.e., \( \int f_0(q)^2 < \infty \).

The map \( \Psi \) is said to be in \( H^1(\mathbb{R}^\nu; \mathcal{B}) \) if \( \Psi \in L^2(\mathbb{R}^\nu; \mathcal{B}) \) and if there are maps \( \partial_1 \Psi, \partial_2 \Psi, \ldots, \partial_\nu \Psi \) for which the following holds

(i) Each \( \partial_j \Psi : \mathbb{R}^\nu \to \mathcal{B} \) is a map in \( L^2(\mathbb{R}^\nu; \mathcal{B}) \)

(ii) For each infinitely differentiable map, \( \phi : \mathbb{R}^\nu \to \mathcal{B} \), of compact support with derivatives \( \partial_j \phi \), we have the relation
\[
\int_{\mathbb{R}^\nu} \text{Tr}[\partial_j \phi(q)\Psi(q)]dq = -\int_{\mathbb{R}^\nu} \text{Tr}[\phi(q)\partial_j \Psi(q)]dq \quad (A.5)
\]
for each \( j \). (Note: to say that \( \phi \) is differentiable means that for every \( q \in \mathbb{R}^\nu \), \( \lim_{\varepsilon \to 0} \|\varepsilon^{-1}[\phi(q + \varepsilon e_j) - \phi(q)] - \partial_j \phi(q)\| = 0 \) with \( e_j \) being the unit vector in the \( j^{th} \) direction. Since \( \phi \) has compact support this limit is uniform in \( q \).) Clearly \( \partial_j \Psi^\dagger = (\partial_j \Psi)^\dagger \).

It is easy to verify that \( H^1(\mathbb{R}^\nu; \mathcal{B}) \) is a Hilbert space with inner product
\[
(\Psi, \Psi') = \int_{\mathbb{R}^\nu} \text{Tr}[\Psi^\dagger(q)\Psi'(q)] + \sum_{j=1}^\nu \partial_j \Psi^\dagger(q)\partial_j \Psi'(q)]dq. \quad (A.6)
\]
Clearly, $\Psi$ is in $H^1$ (or in $L^2$) if and only if $\Psi^\dagger$ is in $H^1$ (or in $L^2$). This class, $H^1(R^\nu; B)$, is precisely the class needed for quantum mechanics, i.e., so that the variational energy $T_j(\Psi)$ can be defined and so that the norm $\int \text{Tr}\Psi^\dagger\Psi$ can be defined. For matrix–valued functions (i.e., $\mathcal{H}$ is finite dimensional) the properties of measurability, being in $L^2$ and being in $H^1$ are just the ordinary meaning of these properties applied to each matrix element of $\Psi$ considered as a function on $R^\nu$.

We are indebted to Jan Philip Solovej for very considerable help with the following.

**THEOREM.** Let $\Psi$ be in $H^1(R^\nu; B)$. Then $|\Psi|$ and $|\Psi^\dagger|$ are in $H^1(R^\nu; B)$ and, for each $j$

$$2T_j(\Psi) \geq T_j(|\Psi|) + T_j(|\Psi^\dagger|). \quad (A.7)$$

In particular, if $\Psi(q)$ is self-adjoint for all $q$ then

$$T_j(\Psi) \geq T_j(|\Psi|). \quad (A.8)$$

**Remark:** If $\Psi$ is not self-adjoint it is quite possible that $T_j(\Psi) < T_j(|\Psi|)$. But then $T_j(\Psi) > T_j(|\Psi^\dagger|)$.

**Proof:** It suffices to prove the theorem when $\Psi(q)$ is self-adjoint for all $q$. To see this, consider the Hilbert space $\mathcal{H}_2 = \mathcal{H} \oplus \mathcal{H}$ and replace $\Psi$ by the self adjoint operator $\Psi_2 = \begin{pmatrix} 0 & \Psi^\dagger \\ \Psi & 0 \end{pmatrix}$. Then $|\Psi_2| = \begin{pmatrix} |\Psi| & 0 \\ 0 & |\Psi^\dagger| \end{pmatrix}$ and (A.7) becomes $T_j(\Psi_2) \geq T_j(|\Psi_2|)$.

The first task is to show that $|\Psi|$ is measurable. Our definition of measurability given above is the standard one, namely the inverse image of an open ball in the Banach space $B$ is measurable. Now the map $\Psi \to |\Psi|$ is continuous in the $B$ norm and hence, by a standard result, $|\Psi|$ is measurable.

Let $v_1, v_2 \ldots$, be an orthonormal basis for $\mathcal{H}$. Matrix elements $(v_\alpha, Av_\beta)$ will be denoted by $A_{\alpha\beta}$. It is easy to verify that $\partial_j(\phi_{\alpha\beta}) = (\partial_j \phi)_{\alpha\beta}$ in the classical sense if $\phi$ is differentiable. If $\Psi$ has distributional derivatives then $\partial_j(\Psi_{\alpha\beta}) = (\partial_j \Psi)_{\alpha\beta}$ in the *ordinary* distributional sense. [Simply take $\phi(q) = h(q)|v_\beta\rangle\langle v_\alpha|$ in (A.5), with $h$ being an ordinary infinitely differentiable function of compact support.] Another important preliminary remark is that by Fubini’s theorem $\sum_{\alpha,\beta} \int_{R^\nu} K_{\alpha\beta}(q)\,dq = \int_{R^\nu} \sum_{\alpha,\beta} K_{\alpha\beta}(q)\,dq$ for any nonnegative, measurable functions $K_{\alpha\beta}(q)$.
For any $\Psi$ in $H^1(\mathbb{R}^\nu; B)$ (including $\phi$, as a special case) we define $\partial_{j\varepsilon}\Psi(q) = \varepsilon^{-1}[\Psi(q+\varepsilon e_j) - \Psi(q)]$. By the fundamental theorem of calculus for distributions

$$ [\partial_{j\varepsilon}\Psi(q)]_{\alpha\beta} = \partial_{j\varepsilon}[\Psi(q)]_{\alpha\beta} = \int_{0}^{1} \partial_{j}[\Psi(q + t\varepsilon e_j)]_{\alpha\beta} dt = \int_{0}^{1} [\partial_{j}\Psi(q + t\varepsilon e_j)]_{\alpha\beta} dt \quad (A.9) $$

Thus, by Fubini’s theorem and Schwarz’s inequality,

$$ \int_{\mathbb{R}^\nu} \text{Tr}[\partial_{j\varepsilon}\Psi(q)]^2 dq = \sum_{\alpha,\beta} \int_{\mathbb{R}^\nu} \left\{ \int_{0}^{1} [\partial_{j}\Psi(q + t\varepsilon e_j)]_{\alpha\beta} dt \right\}^2 dq \leq \sum_{\alpha,\beta} \int_{\mathbb{R}^\nu} \left[ \int_{0}^{1} [\partial_{j}\Psi(q + t\varepsilon e_j)]_{\alpha\beta} dt dq = \int_{\mathbb{R}^\nu} \text{Tr}[\partial_{j}\Psi(q)]^2 dq. \quad (A.10) \right. $$

Therefore, $\partial_{j\varepsilon}\Psi$ is uniformly (in $\varepsilon$) bounded in $L^2(\mathbb{R}^\nu; B)$.

Now we are ready to study $|\Psi|$, and we begin with a little lemma. If $N$ and $M$ are self-adjoint Hilbert-Schmidt operators then

$$ \text{Tr}(N - M)^2 \geq \text{Tr}(|N| - |M|)^2. \quad (A.11) $$

This is equivalent to $\text{Tr}NM \leq \text{Tr}|N||M|$. If we write $2N_\pm = |N| \pm N$ and $2M_\pm = |M| \pm M$, we have that $N_\pm$ and $M_\pm$ are positive semidefinite, and our requirement now reads $\text{Tr}[M_+N_- + M_-N_+] \geq 0$. But this is true because $\text{Tr}M_+N_- = \text{Tr}M_+^{1/2}N_-M_-^{1/2} > 0$, etc.

From (A.11) we have that $\text{Tr}[\partial_{j\varepsilon}|\Psi|]^2 \leq \text{Tr}[\partial_{j\varepsilon}\Psi]^2$, from which we deduce that $\partial_{j\varepsilon}|\Psi|$ is uniformly bounded in $L^2(\mathbb{R}^\nu; B)$. More precisely, by (A.10) and (A.11),

$$ \int_{\mathbb{R}^\nu} [\partial_{j\varepsilon}|\Psi|(q)]^2 dq \leq \int_{\mathbb{R}^\nu} \text{Tr}[\partial_{j}\Psi(q)]^2 dq. \quad (A.12) $$

Since $L^2(\mathbb{R}^\nu; B)$ is a Hilbert space, the boundedness shown above plus the Banach-Alaoglu theorem implies that there is a sequence $\varepsilon_1, \varepsilon_2, \ldots$, tending to zero such that

$$ \partial_{j\varepsilon_n}|\Psi| \rightharpoonup \rho_j, \quad (A.13) $$

as $n \to \infty$, where $\rho_j$ is a map in $L^2(\mathbb{R}^\nu; B)$ and where the convergence is in the weak sense. Since, $\partial_{j\varepsilon}\phi(q)$ converges to $\partial_j\phi(q)$ uniformly (in Hilbert-Schmidt norm) we can write (A.5), using (A.13), as

$$ \int_{\mathbb{R}^\nu} \text{Tr}[\phi\rho_j] = \lim_{\varepsilon \to 0} \int_{\mathbb{R}^\nu} \text{Tr}[\phi\partial_{j\varepsilon}|\Psi|] = -\lim_{\varepsilon \to 0} \int_{\mathbb{R}^\nu} \text{Tr}[\partial_{j\varepsilon}\phi|\Psi|] = -\int_{\mathbb{R}^\nu} \text{Tr}[\partial_j\phi|\Psi|] \quad (A.14) $$

23
The first equality in (A.14) is the weak convergence of $\partial_{j\varepsilon}\Psi$; the second is just a trivial change of variables in the $q$-integration; the third is the uniform convergence of $\partial_{j\varepsilon}\phi$. Equation (A.14) holds for every $\phi$. By uniqueness of the distributional derivative for ordinary functions [and choosing $\phi(q) = h(q)|v_\beta\rangle\langle v_\alpha|$ as before] we conclude that $(\rho_j)_{\alpha\beta} = (\partial_j|\Psi|)_{\alpha\beta}$, and hence $\rho_j = \partial_j|\Psi|$. However, norms cannot increase under weak limits and thus (A.8) follows from (A.12). Q.E.D.
