PREPROJECTIVE ANALOGUE OF THE CONE CONSTRUCTION

BENJAMIN COOPER and JOSHUA SUSSAN

(communicated by Charles A. Weibel)

Abstract
We formulate a relative, representation theoretic, notion of the algebraic cone construction. This motivates a generalization of the cone corresponding to a preprojective algebra.

1. Introduction

One of the most important structures in homological algebra is the cone $C(f)$ of a map $f$

$$f \rightsquigarrow C(f).$$

This paper begins with a generalization of this construction, to each finite dimensional algebra $B$, there is an analogue of the association above. Specifically, if $B$ is a finite dimensional algebra and $\mathcal{C}$ is an $A_\infty$-category, then there is a notion of a $B$-map $f_B$ in $\mathcal{C}$ and a $B$-cone construction $C_B(f_B)$ in $\mathcal{C}$. This definition is natural from the perspective of the relative definition of the cone construction, which is reviewed in Section 3.1. In particular, if the algebra $B$ is the type $A_2$ Dynkin quiver path algebra, then our construction specializes to the usual cone.

We now describe a particular finite dimensional algebra $B$ which leads to an interesting $B$-cone construction. To any quiver $Q$, one may form the path algebra $kQ$. For each edge of the quiver $Q$, adding an edge oriented in the opposite direction produces a new quiver $\overline{Q}$. The quotient of the path algebra $k\overline{Q}$ by a certain ideal (see Section 4) is the preprojective algebra $\Pi Q$ associated to $Q$. The main task of our paper is to study the new cone construction when the algebra $B$ is the preprojective algebra $\Pi A_2$ of the type $A_2$ Dynkin quiver

$$A_2 \text{ is to } f \rightsquigarrow C(f) \text{ as } \Pi A_2 \text{ is to Section 4.}$$

This choice is inspired by the important relationship between $A_n$ and $\Pi A_n$ in geometric representation theory. At the end of the paper, we relate these new preprojective cones to the Fukaya categories of surfaces.

In the remainder of the introduction, we explain these ideas in more detail.

If $f: X \to Y$ is a chain map, then the algebraic cone of $f$ is the chain complex...
This familiar gadget is central to many important concepts in mathematics. In their study of differential graded algebras, Bondal and Kapranov formulated the requirement that a map contain a cone in terms of the completeness of the Yoneda embedding \([3]\). In creating the foundations of \(A_\infty\)-categories, Kontsevich and Seidel found a certain \(A_\infty\)-category \(\Delta\) which corepresents distinguished triangles, in particular, this category characterizes algebraic cones up to homotopy \([7, 17]\). In this paper, this relative characterization of cones is generalized by replacing the role of \(\Delta\) by an \(A_\infty\)-category associated to an arbitrary finite dimensional algebra \(B\).

The rest of the paper investigates the implications of this definition when the algebra \(B\) is specialized to be the next most complicated choice after \(\Delta\). In more detail, since the category \(\Delta\) is determined by the representation theory of the \(A_2\)-quiver, we study the analogue of the cone when the path algebra \(kA_2\) is replaced by the preprojective algebra \(\Pi A_2\). The preprojective algebra \(\Pi Q\) is the simplest non-trivial replacement for the path algebra \(kQ\). In part, this is because \(kQ\) naturally embeds in \(\Pi Q\), and as \(kQ\)-module, \(\Pi Q\) decomposes as a direct sum of preprojective \(kQ\)-modules. The moduli space of \(\Pi Q\) finite dimensional representations naturally fibers over the corresponding moduli space of \(kQ\) representations and this relationship has important consequences in representation theory. For more details see \([16]\).

In order to understand the preprojective cone, in Theorem 4.7 we use homotopy perturbation theory to compute the minimal model \(\Pi\) of the dg enhancement of the \(Ext\)-algebra of indecomposable objects in the category \(\Pi A_2\)-mod, where

\[
\Pi = Ext^*_{\Pi A_2}(I, I), \quad I = \bigoplus M
\]

and the direct sum is over all indecomposable \(\Pi A_2\)-modules (up to isomorphism). This results in a complete description of the \(A_\infty\)-structure on a tetrahedron with vertices labeled by indecomposable \(\Pi A_2\)-modules. This \(A_\infty\)-structure allows us to study the derived mapping spaces \(\mathbb{R}Hom(\Pi, D)\) as \(D\) ranges over other \(A_\infty\)-categories. Since preprojective distinguished triangles are homotopy classes of such functors \([\mathcal{F}] \in Ob(H^0(\mathbb{R}Hom(\Pi, D)))\), we are able to formulate conclusions about them from the minimal model for \(\Pi\).

In short, a preprojective map is a pair of cycles

\[
f: A \Rightarrow B: g
\]

and the preprojective distinguished triangle is constructed from the algebraic cones \(C(f)\) and \(C(g)\) together with canonical maps between them

\[
(12): C(f) \Rightarrow C(g): (21).
\]

In addition to the ordinary distinguished triangles, which are determined individually by \(f\) and \(g\), the preprojective distinguished triangle determines families of Postnikov systems, or iterated cone constructions, of arbitrary length. The sense in which this data is precisely encoded by the \(A_\infty\)-structure computed in Theorem 4.7 is discussed in Remark 4.14.
Finally, these observations are related to Fukaya categories of surfaces. In Proposition 4.19, we conclude by constructing a strict $A_\infty$-functor from the wrapped Fukaya category of a pair of paints $W(P)$ to a slight modification of the preprojective category $\Pi$.

This paper is part of an ongoing study of the relativization of structures in homological algebra and relationships to the categorification program in low dimensional topology. It has been made into a separate paper because it contains the lengthy computation of an $A_\infty$-structure.

2. The language of $A_\infty$-categories

An $A_\infty$-category is a category in which the associativity of composition holds only up to coherent homotopy. The purpose of this section is to explain how the homotopy transfer theorem [13] implies that every differential graded category $\mathcal{C}$ uniquely determines an $A_\infty$-category $H^0(\mathcal{C})$ and how homotopy classes of maps between dg categories can be computed from this $A_\infty$-category [6].

2.1. $A_\infty$-categories and $A_\infty$-functors

Definition 2.1. An $A_\infty$-category $\mathcal{C}$ consists of a collection of objects $\text{Ob}(\mathcal{C})$ and a $\mathbb{Z}$-graded $k$-module of morphisms $\text{Hom}(X, Y) = \bigoplus_{t \in \mathbb{Z}} \text{Hom}^t(X, Y)$ for each pair of objects $X, Y \in \text{Ob}(\mathcal{C})$ together with maps

$$m_d : \text{Hom}(X_{d-1}, X_d) \otimes \cdots \otimes \text{Hom}(X_0, X_1) \to \text{Hom}(X_0, X_d)[2 - d], \quad d \geq 1,$$

which satisfy the relations

$$\sum_{l=0}^d \sum_{n=0}^{d-l} (-1)^{\|n\| + \cdots + |f_1|} m_d - t + 1(f_d, \ldots, f_{n+t+1}, m_l(f_{n+l}, \ldots, f_{n+1}), f_n, \ldots, f_1) = 0, \quad (1)$$

where $\|n\| = |f_n| + \cdots + |f_1| - n$ and $d \geq 1$.

An $A_\infty$-category $\mathcal{C}$ is said to be strictly unital when there is a unique degree zero morphism $1_X \in \text{Hom}^0(X, X)$ for each $X \in \text{Ob}(\mathcal{C})$ which satisfies

$$m_2(f, 1_X) = f, \quad (-1)^{|g|}m_2(1_X, g) = g,$$

and $m_d(\ldots, 1_X, \ldots) = 0$, when $d \neq 2, \quad (2)$

for any maps $f : X \to A$ or $g : B \to X$ and any object $X \in \text{Ob}(\mathcal{C})$.

Example 2.2. Additive $k$-linear categories and differential graded categories are examples of $A_\infty$-categories in which all of the higher multiplications $m_d$, for $d > 2$, vanish. Any $A_\infty$-category $\mathcal{C}$ determines a dg category $\tau_{>2}\mathcal{C}$ which is obtained by forgetting the maps $m_d$ for $d > 2$. Non-trivial examples of $A_\infty$-categories appear in Section 4.
In an $A_\infty$-category $C$, there is a degree 1 map, $m_1: \text{Hom}(X_0, X_1) \to \text{Hom}(X_0, X_1)$, for each pair of objects $X_0, X_1 \in \text{Ob}(C)$, which satisfies $m_1 \circ m_1 = 0$; the simplest $A_\infty$-relation above. Taking homology everywhere with respect to these maps produces the homotopy category defined below.

**Definition 2.3.** The homotopy category $H^0(C)$ of an $A_\infty$-category $C$ is the $k$-linear category with the same objects as $C$ and morphisms given by homology classes of maps $[f] \in H^*(\text{Hom}(X, Y), m_1)$ for each $X, Y \in \text{Ob}(C)$. The composition is defined by

$$[f_2] \circ [f_1] = (-1)^{|f_1|} m_2(f_2, f_1).$$

**Example 2.4.** Suppose that $R$ is ring and $M$ is an $R$-module. If $P$ is a projective resolution of $M$

$$P = [\cdots \to P_i \xrightarrow{d_i} P_{i+1} \to \cdots \to P_1 \to P_0] \to M \to 0$$

then the endomorphisms $\text{End}^*_P(P)$ of $P$ form a differential graded category with one object.

In more detail, set $\text{End}^n(P) = \prod_{i \in \mathbb{Z}} \text{Hom}(P_i, P_{i+n})$. If $f = \{f_i: P_i \to P_{i+n}\}$ and $g = \{g_i: P_i \to P_{i+m}\}$ are maps of degree $n$ and $m$, respectively, then the composite

$$g \circ f = \{g_{i+n} \circ f_i: P_i \to P_{i+n+m}\}$$

is an endomorphism of degree $n + m$. This composition determines a multiplication $\mu$. If $f = \{f_i: P_i \to P_{i+n}\}$ then $df = \{(df)_i: P_i \to P_{i+n+1}\}$ where

$$(df)_i = d_{i+n} \circ f_i - (-1)^n f_{i+1} d_i: P_i \to P_{i+n+1}.$$ 

The homotopy category $H^0(\text{End}^*_P(P))$ of $\text{End}^*_P(P)$ is the $\text{Ext}$-algebra of $M$

$$H^0(\text{End}^*_P(P)) \cong \text{Ext}_A^*(M).$$

**Definition 2.5.** An $A_\infty$-functor $F: C \to D$ between $A_\infty$-categories consists of a map $F: \text{Ob}(C) \to \text{Ob}(D)$ and multilinear maps

$$F^d: \text{Hom}_C(X_{d-1}, X_d) \otimes \cdots \otimes \text{Hom}_C(X_0, X_1) \to \text{Hom}_D(F(X_0), F(X_d))[1 - d]$$

for $d \geq 1$, which satisfy the equations

$$\sum_{r \geq 1} \sum_{s_1, \ldots, s_r} m_r^D(F^{s_r}(f_d, \ldots, f_{d-s_r+1}), \ldots, F^{s_1}(f_{s_1}, \ldots, f_1)) = \sum_{i, n} (-1)^{i+n} F^{d-i+1}(f_d, \ldots, f_{n+i+1}, m_i^C(f_{n+i}, \ldots, f_{n+1}), f_n, \ldots, f_1).$$

The sign $\frac{(-1)^r}{r!}$ is as in Definition 2.1 and the first sum is over all partitions: $s_1 + \cdots + s_r = d$. The collection $\{F^d\}$ is also required to behave well with respect to units

$$F^1(1_X) = 1_{F(X)} \quad \text{and} \quad F^d(\ldots, 1_X, \ldots) = 0 \text{ for } d \geq 2.$$ 

Any such $A_\infty$-functor $F: C \to D$ induces a map $H^0(F): H^0(C) \to H^0(D)$ between the associated homotopy categories. An $A_\infty$-functor is a quasi-isomorphism or $A_\infty$-equivalence when $H^0(F)$ is an equivalence of categories.

If $F: C \to D$ is an $A_\infty$-functor then there is a dg functor $\tau_{\geq 2}(F): \tau_{\geq 2}C \to \tau_{\geq 2}D$ determined by the map $F^1$ between the truncations of $C$ and $D$, see Example 2.2.
Two $A_\infty$-functors $F: \mathcal{C} \to \mathcal{D}$ and $G: \mathcal{D} \to \mathcal{E}$ can be composed to produce an $A_\infty$-functor $G \circ F: \mathcal{C} \to \mathcal{E}$, the $d$th component of which is given by the equation

$$(G \circ F)^d(f_d, \ldots, f_1) = \sum_{r} \sum_{s_1, \ldots, s_r} G^r(F^s_r(f_d, \ldots, f_{d-s_r+1}), \ldots, F^s_1(f_{s_1}, \ldots, f_1)).$$

**Definition 2.6.** Let $A_\infty(\mathcal{C}, \mathcal{D})$ denote the $A_\infty$-category of $A_\infty$-functors from $\mathcal{C}$ to $\mathcal{D}$. If $F, G: \mathcal{C} \to \mathcal{D}$ are two objects in this category, then a morphism (pre-natural transformation) $T \in \text{Hom}^g(F, G)$ of degree $g$ from $F$ to $G$ is a sequence $T = (T^0, T^1, \ldots)$, where

$$T^d: \text{Hom}_\mathcal{C}(X_{d-1}, X_d) \otimes \cdots \otimes \text{Hom}_\mathcal{C}(X_0, X_1) \to \text{Hom}_\mathcal{D}(F(X_0), G(X_d))[g-d],$$

for all sequences of objects $(X_0, \ldots, X_d)$ in $\mathcal{C}$. There is an $A_\infty$-structure on the collection of pre-natural transformations. For more details see [17, §(1d)].

### 2.2. Homotopy perturbation theory

Since an $A_\infty$-category is a category in which the composition is associative only up to coherent homotopy, deforming an $A_\infty$-category by a homotopy yields an $A_\infty$-equivalent $A_\infty$-category. The purpose of the homotopy transfer theorem is to make this precise, see [17, Prop. 1.12] or [13] for detailed arguments and signs.

If $\mathcal{C}$ and $\mathcal{D}$ are dg categories with the same set of objects, then we say that $\mathcal{D}$ is a perturbation of $\mathcal{C}$ when there are dg functors $f: \mathcal{C} \to \mathcal{D}$ and $g: \mathcal{D} \to \mathcal{C}$ so that $f$ and $g$ are identity maps on objects, $1_D = fg$, and for each pair of objects $x, y \in \mathcal{C}$ there is a homotopy $h_{x,y}: \text{Hom}_\mathcal{C}(x, y) \to \text{Hom}_\mathcal{C}(x, y)$ of degree $-1$ which satisfies $dh_{x,y} - h_{x,y}d = 1 - gf$ where $gf$ is the map induced by $g$ and $f$ between Hom-spaces.

**Theorem 2.7.** Suppose that $\mathcal{C}$ is an $A_\infty$-category, $\tau_{>2}\mathcal{C}$ is the dg category determined by forgetting the higher $m_n$-maps when $n \geq 3$ and $\mathcal{D}$ is a perturbation of $\tau_{>2}\mathcal{C}$ with dg functors

$$f: \tau_{>2}\mathcal{C} \to \mathcal{D} \quad \text{and} \quad g: \mathcal{D} \to \tau_{>2}\mathcal{C}.$$  

Then there is an $A_\infty$-category $(\mathcal{D}', \{m_n^{\mathcal{D}'}\}_{n>3})$ and there are $A_\infty$-functors

$$f': \mathcal{C} \to \mathcal{D}' \quad \text{and} \quad g': \mathcal{D}' \to \mathcal{C},$$

which determine an $A_\infty$-equivalence $\mathcal{C} \simeq \mathcal{D}'$ and restrict to the initial data: $\tau_{>2}\mathcal{D}' = \mathcal{D}$, $\tau_{>2}(f') = f$ and $\tau_{>2}(g') = g$.

Since $m_1^{\mathcal{D}'} = m_1^{\mathcal{D}}$ and $m_2^{\mathcal{D}'} = m_2^{\mathcal{D}}$, one can view $\mathcal{D}'$ as an extension of the dg structure on $\mathcal{D}$.

An important special case of this theorem shows that every $A_\infty$-category $\mathcal{C}$ is $A_\infty$-equivalent to its own homotopy category $H^0(\mathcal{C})$, [17, Rmk. 1.13]. Following Example 2.4, when $P$ is a projective resolution of an $R$-module $M$, there is an $A_\infty$-structure on the Ext-algebra $\text{Ext}^*(M)$ making it $A_\infty$-equivalent to the dg algebra $\text{End}^*(P)$ (with differential $d$ and multiplication $\mu$)

$$\text{End}^*(P) \cong \text{Ext}^*(M).$$

For this special case, following [10, Theorem 3.2], the equivalence of Theorem 2.7...
may be expressed using maps
\[
H \circ \text{End}^*(P) \xrightarrow{p} \text{Ext}^*(M),
\]
where \( i \) and \( p \) are morphisms of degree zero and \( H \) is a homogeneous map of degree 
\(-1\) such that
\[
pi = 1, \quad 1 - ip = d(H), \quad H^2 = 0.
\]
Then the \( A_\infty \)-structure on \( \text{Ext}^*(M) \) is given by
\[
m_n = \sum_T m^T_n,
\]
where \( T \) ranges over planar rooted binary trees with \( n \) leaves and \( m^T_n \) is given by
composing the tree-shaped diagram obtained by labeling each leaf by \( i \), each branch point by \( \mu \), each internal edge by \( H \) and the root by \( p \).

For example, the two trees determining \( m_3 \) are pictured below.

\[
\begin{align*}
i & \quad i \\
\mu & \quad \mu \\
H & \quad H \\
p & \quad p
\end{align*}
\]

2.3. Homotopy classes of functors

The category of differential graded categories \( \text{dgcat}_k \) over \( k \) can be given the structure of a model category \( Hq^e \). A weak equivalence in this homotopy theory is a dg functor \( f : \mathcal{C} \to \mathcal{D} \) which satisfies two properties:

1. \( H^0(f) : H^0(\mathcal{C}) \to H^0(\mathcal{D}) \) is essentially surjective.
2. \( f_{x,y} : \text{Hom}_\mathcal{C}(x, y) \to \text{Hom}_\mathcal{D}(f(x), f(y)) \) is a quasi-isomorphism for all \( x, y \in \text{Ob}(\mathcal{C}) \).

The homotopy category \( \text{Ho}(\text{dgcat}_k) \) of dg categories is the category obtained by formally inverting the weak equivalences above. Toën \[19\] proved that category \( \text{Ho}(\text{dgcat}_k) \) is closed and monoidal. In particular, there are dg categories \( \mathcal{C} \otimes^L \mathcal{D} \) and \( \mathcal{RHom}(\mathcal{D}, \mathcal{E}) \) together with natural isomorphisms
\[
\text{Hom}(\mathcal{C} \otimes^L \mathcal{D}, \mathcal{E}) \xrightarrow{\sim} \text{Hom}(\mathcal{C}, \mathcal{RHom}(\mathcal{D}, \mathcal{E})).
\]

Unfortunately, Toën’s description of the dg category \( \mathcal{RHom}(\mathcal{D}, \mathcal{E}) \) is somewhat complicated. The purpose of this section is to discuss an alternative way to compute the derived space of mappings using \( A_\infty \)-categories. G. Faonte proved the theorem below \[6, \text{Thm. 1.7} \]; the statement is sometimes attributed to Kontsevich.
Theorem 2.8. If $\mathcal{D}$ and $\mathcal{E}$ are dg categories over a field of characteristic 0, then the derived mapping category $\mathcal{D}$ is naturally isomorphic to the dg category of $A_\infty$-functors from $\mathcal{D}$ to $\mathcal{E}$

$$\mathcal{D} \to A_\infty(\mathcal{D}, \mathcal{E}).$$

3. Algebraic cones

If $f: X \to Y$ is a continuous map between topological spaces $X$ and $Y$ then the cone $C(f)$ of $f$ is given by the pushout

$$C(f) = CX \cup_f Y, \quad \text{where} \quad CX = X \times [0,1]/X \times \{1\}.$$  

This topological cone acts as a stand in for the quotient $Y/im(f)$ in the long exact sequence of homology groups associated to the quotient

$$\cdots \to H_n(X) \xrightarrow{f_*} H_n(Y) \to H_n(C(f)) \to H_{n-1}(X) \to \cdots$$

because $H_n(C(f)) \cong H_n(Y/im(f))$ for $n > 0$. After passing from topological spaces to cochain complexes, the cone $C(f)$ of a map $f: (X, d_X) \to (Y, d_Y)$ is the cochain complex formed by

$$C(f) = (X[1] \oplus Y, d_{C(f)}), \quad \text{where} \quad d_{C(f)} = \begin{pmatrix} -d_X & 0 \\ f & d_Y \end{pmatrix}. \quad (5)$$

In analogy with the relationship between the homology of quotient space and the topological cone, when $f: X \to Y$ is a map in an abelian category $\mathcal{A}$, the algebraic cone is isomorphic to the quotient in the derived category $D^b(\mathcal{A})$, $C(f) \cong Y/im(f)$. This is why the existence of objects equivalent to algebraic cones is a principal component of the definition of a triangulated category. For a similar discussion of cones see [1, §3.1]. In the remainder of this section we will reformulate the requirement that an algebraic cone exists in a manner which admits generalizations.

When an $A_\infty$-category $\mathcal{C}$ is pretriangulated each cycle $f \in Hom_\mathcal{C}(X, Y)$, has a cone $C(f) \in Ob(\mathcal{C})$. Roughly speaking, a cone is said to exist in $\mathcal{C}$ when there is an object $C(f) \in Ob(\mathcal{C})$ representing the cone of $f$ in the image of the Yoneda embedding. Let us explain precisely what we mean. For any $A_\infty$-category $\mathcal{C}$, the category of modules $\mathcal{C} \cdot \text{-mod} = A_\infty(\mathcal{C}, \text{Ch}_h)$ consists of $A_\infty$-functors from $\mathcal{C}$ to the dg category of cochain complexes $\text{Ch}_h$. There is a Yoneda embedding of $\mathcal{C}$ into its associated category of modules $\mathcal{C} \cdot \text{-mod}$

$$\mathcal{C} \to \mathcal{C} \cdot \text{-mod}, \quad X \mapsto \mathcal{C}(X), \quad \text{where} \quad \mathcal{C}(X) = \text{Hom}(\mathcal{C}, X, Y).$$

This is an embedding in the sense that the associated functor $H^0(\mathcal{C}) : H^0(\mathcal{C}) \to H^0(\mathcal{C} \cdot \text{-mod})$ between homotopy categories is full and faithful.

Definition 3.1. If $f \in Hom_\mathcal{C}(Y_0, Y_1)$ is a cycle, (so $m_1(f) = 0$), then the cone $\mathcal{C}(f) \in Ob(\mathcal{C} \cdot \text{-mod})$ of $f$ is the $\mathcal{C}$-module determined by the assignment

$$\mathcal{C}(f)(X) = \text{Hom}(\mathcal{C}, X, Y_0)[1] \oplus \text{Hom}(\mathcal{C}, X, Y_1)$$

and structure maps

$$m^e_d((b_0, b_1), a_{d-1}, \ldots, a_1) = (m_d(b_0, a_{d-1}, \ldots, a_1), m_d(b_1, a_{d-1}, \ldots, a_1) + m_{d+1}(f, b_0, a_{d-1}, \ldots, a_1)).$$
Remark 3.2. The definition stems from the observation that for any $A_\infty$-category $\mathcal{C}$, the homotopy category of modules $H^0(\mathcal{C}\text{-mod})$ is triangulated in the sense of Verdier and $\mathcal{C}(f) \cong C(\mathcal{Y}(f))$ where $\mathcal{Y}(f): \mathcal{Y}_Y \to \mathcal{Y}_1$. 

Remark 3.3. When $\mathcal{C} = Ch_k$, so $m_d = 0$ for $d > 2$, the $A_\infty$-cone in Definition 3.1 above is equivalent to the image of the algebraic cone in equation (5) under the Yoneda map.

This justifies the next definition.

Definition 3.4. Suppose that $\mathcal{C}$ is an $A_\infty$-category and $f \in Hom_{\mathcal{C}}(Y_0, Y_1)$ is a cycle, so that $m_1(f) = 0$, then an object $X \in Ob(\mathcal{C})$ is a cone of $f$ in $\mathcal{C}$ when there is an isomorphism

$$\mathcal{Y}_X \cong \mathcal{C}(f)$$

in the homotopy category $H^0(\mathcal{C}\text{-mod})$ of $\mathcal{C}$-modules. In particular, $f$ has a cone $C(f)$ in $\mathcal{C}$ when there is such a cone object $X$ in $\mathcal{C}$. Since the Yoneda embedding is full and faithful up to homotopy, any two cones of a single $f$ must be isomorphic in $H^0(\mathcal{C})$.

Use of the Yoneda embedding to characterize the cone construction in dg and $A_\infty$-categories appeared in [3, 18].

3.1. A relative perspective on triangles

In what follows we review a different perspective of triangulated categories often attributed to Kontsevich, see [7], [17, I, (3g)].

If $f \in Hom_{\mathcal{C}}(X, Y)$ is a cycle of degree $|f| = 0$ and $Z \in Ob(\mathcal{C})$ is the cone on $f$, as above, then there are cycles $g: Y \to Z$ and $h: Z \to X$ of degrees $|g| = 0$ and $|h| = 1$ respectively which is summarized by

$$X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1].$$

While any such collection of maps within an $A_\infty$-category $\mathcal{C}$ could be called a triangle, a distinguished triangle must satisfy the additional properties:

1. In the homotopy category, composing any two adjacent maps is zero

$$m_2(g, f) = 0, \quad m_2(h, g) = 0 \quad \text{and} \quad m_2(f, h) = 0. \quad (6)$$

2. The Massey product of three consecutive maps is identity

$$m_3(h, g, f) = 1_X, \quad m_3(f, h, g) = 1_Y \quad \text{and} \quad m_3(g, f, h) = 1_Z. \quad (7)$$

It happens that these conditions suffice to distinguish distinguished triangles. In particular, $Z \simeq C(f)$ when conditions (1) and (2) hold. There is a category $\Delta$ which packages the information above in such a way that $A_\infty$-functors $t: \Delta \to \mathcal{C}$ from $\Delta$ to $\mathcal{C}$ correspond to distinguished triangles in $\mathcal{C}$.

Definition 3.5. There is an $A_\infty$-category $\Delta$ which encodes the constraints satisfied by a distinguished triangle. The objects are given by the set $Ob(\Delta) = \{A, B, C\}$
and maps are given by identity maps $1_A, 1_B$ and $1_C$ together with maps $\alpha: A \to B$, $\beta: B \to C$ and $\gamma: C \to A$ of degrees $|\alpha| = 0$, $|\beta| = 0$ and $|\gamma| = 1$, respectively.

\begin{center}
\begin{tikzpicture}
  \node (A) at (0,0) {$A$};
  \node (B) at (-2,-1) {$B$};
  \node (C) at (2,-1) {$C$};
  \draw[->] (A) to node[auto] {$\gamma$} (C);
  \draw[->] (A) to node[auto, swap] {$\alpha$} (B);
  \draw[->] (B) to node[auto] {$\beta$} (C);
\end{tikzpicture}
\end{center}

The $A_\infty$-structure is determined by the requirements of strict unitality, as in Definition 2.1, and equations (6) and (7) above. This is the partially wrapped Fukaya category of the disk with three marked points on the boundary, see Definition 4.15 [5, 9, 14].

**Theorem 3.6.** A triangle $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]$ in $H^0(\mathcal{C})$ is distinguished if and only if there is an $A_\infty$-functor $t: \Delta \to \mathcal{C}$ such that

1. $t(A) = X$, $t(B) = Y$ and $t(C) = Z$,
2. $[t](\alpha) = f$, $[t](\beta) = g$ and $[t](\gamma) = h$,

where $[t] = H^0(t): H^0(\Delta) \to H^0(\mathcal{C})$.

Informally, the theorem above says that $A_\infty$-functors correspond to distinguished triangles in a given $A_\infty$-category $\mathcal{C}$. This theorem will be used to rephrase the condition that an $A_\infty$-category $\mathcal{C}$ contains a cone object $C(f)$ for every cycle $f \in \text{Hom}_\mathcal{C}(X, Y)$.

### 3.2. $A_2$-representations as a subcategory

Since the third object $Z$ in a distinguished triangle is determined up to isomorphism by its realization as the cone on the map $f: X \to Y$ between the other two, the category $\Delta$ is Morita equivalent to the subcategory consisting of two objects and a map between them

$$A_2 := [X \xrightarrow{f} Y].$$

This is called the $A_2$-quiver. A module or representation $M$ of $A_2$ consists of two $k$-vector spaces $V$ and $W$ assigned to the objects $X$ and $Y$

$$M(X) = V \quad \text{and} \quad M(Y) = W$$

together with a linear map $M(f): V \to W$. In other words, a functor $A_2 \to \text{Vect}_k$.

A map $q: M \to N$ between two representations is a natural transformation. If $M$ and $N$ are two representations then there is a sum $M \oplus N$ determined by the assignments $(M \oplus N)(X) = M(X) \oplus N(X)$, $(M \oplus N)(Y) = M(Y) \oplus N(Y)$ and $(M \oplus N)(f) = M(f) \oplus N(f)$.

The representations of $A_2$ form the objects of an abelian category $A_2\text{-mod}$ containing precisely three indecomposable objects: $P$, $S_1$ and $S_2$ determined by the table of functors:

1. $P(X) = k$, $P(Y) = k$ and $P(f) = 1_k$.
2. $S_1(X) = k$, $S_1(Y) = 0$ and $S_1(f) = 0$.
3. $S_2(X) = 0$, $S_2(Y) = k$ and $S_2(f) = 0$. 

These modules form a short exact sequence
\[ 0 \to S_2 \to P \to S_1 \to 0, \] (8)
which is universal in the sense that the structure of the category \( A_2 \)-\text{mod} is determined by (8) and the axioms of abelian categories. The space \( \text{Ext}^1(S_1, S_2) \) is spanned by this extension. All of the other \( \text{Ext} \)-groups vanish because \( S_2 \) and \( P \) are projective. From equation (8), we see that the chain complex \( Q = [S_2 \to P] \) is a projective resolution of \( S_1 \). Theorem 2.7 can be used to compute the \( A_{\infty} \)-structure of the \( \text{Ext} \)-algebra:
\[ \text{End}^r(Q \oplus P \oplus S_2) \xrightarrow{\sim} \text{Ext}^r(S_1 \oplus P \oplus S_2) \]
as in Example 2.4. The \( A_{\infty} \)-structure on the right-hand side of this equation is well-known, see [12, App. B. 2], up to sign conventions, it is identical to the category \( \Delta \)
\[ \Delta \cong \text{Ext}^r(S_1 \oplus P \oplus S_2). \]

It is in this way that the \( A_{\infty} \)-category \( \Delta \), the principal datum of a triangulated category and the definition of algebraic cone stem directly from the representation theory of the \( A_2 \)-quiver.

### 3.3. Cones as completions

The discussion above leads us to a generalization of the requirement that an \( A_{\infty} \)-category have cones corresponding to each cycle.

**Definition 3.7.** Suppose that \( \iota : A \subset \overline{A} \) is a pair of \( A_{\infty} \)-categories. Then an \( A_{\infty} \)-category \( C \) is \( \iota \)-complete when the pullback functor: \( \iota^* : \mathbb{R}\text{Hom}(A, C) \to \mathbb{R}\text{Hom}(A, C) \) is quasi-essentially surjective (i.e. \( H^0(\iota^*) \) is essentially surjective).

If \( C \) is \( \iota \)-complete then, up to homotopy, every functor \( F : A \to C \) from \( A \) into \( C \) lifts to a functor \( \tilde{F} : \overline{A} \to C \) in such a way that the diagram below commutes.

\[
\begin{array}{ccc}
A & \xrightarrow{F} & C \\
\downarrow{\iota} & & \downarrow{\tilde{F}} \\
\overline{A} & & \\
\end{array}
\]

**Example 3.8.** Suppose that \( A \) is a diagram category consisting of a collection of disjoint points and \( \overline{A} = CA \) is the cone category obtained by adding an initial object. Then a category \( C \) containing \( A \)-limits will be \( \iota \)-complete (where \( \iota : A \to CA \)).

In examples of most interest the functor \( \iota^* \) is a quasi-equivalence; both quasi-essentially surjective and quasi-fully faithful.

The definition below introduces some terminology to clarify the generalization we are making.

**Definition 3.9.** Suppose \( \iota : A \to \overline{A} \) is a pair as in Definition 3.7 above. A functor \( F : A \to C \) is a **morphism** or \( \iota \)-**morphism**. A lift \( \tilde{F} : \overline{A} \to C \) is a \( \iota \)-distinguished triangle associated \( F \). For any morphism \( F \), the additional information needed to define a lift \( \tilde{F} \) is a **cone** or \( \iota \)-**cone** on \( F \).
Example 3.10. Suppose $B$ is a finite dimensional algebra over $k$ and $S$ is the collection of finite dimensional simple $B$-modules $S \subset B\text{-mod}$. Set $S = \oplus_{M \in S} M$. Then there are $A_\infty$-categories

$$A_B = \text{End}^*(S) \quad \text{and} \quad \bar{A}_B = \text{End}^*(S \oplus B).$$

In the second term, $B$ is used to denote the algebra $B$ viewed as a left $B$-module over itself. After applying Theorem 2.7 to both sides, the inclusion $A_B \hookrightarrow \bar{A}_B$ of dg algebras determines an $A_\infty$-functor $\iota: A_B \to \bar{A}_B$. In this sense, there is a notion of $\iota$-completeness associated to every finite dimensional algebra $B$.

When $B = A_2$, Theorem 3.6 combines with the discussion in Section 3.2 to show that an $A_\infty$-category $C$ contains a cone $C(f)$ for every cycle $f \in C$ if and only if $C$ is $\iota$-complete as in the example above.

Since there are many choices of $\iota$, it is important to limit investigation to interesting choices. In the next section we will investigate this condition for the preprojective algebra of the $A_2$-quiver. For this category, it might make sense to call the $\iota$-distinguished triangles, distinguished pyramids.

4. Preprojective cones

In this section we introduce the preprojective algebras $\Pi Q$ and compute the $A_\infty$-category $\Pi$ associated to the derived endomorphisms of indecomposable modules over $\Pi A_2$. The category $\Pi$ constitutes our generalization of the category $\Delta$ which was seen to describe distinguished triangles in Theorem 3.6.

A quiver is a finite directed graph $Q = (Q_0, Q_1)$ consisting of vertices $Q_0$ and edges $Q_1$. Each edge $f \in Q_1$ has a start $s(f) \in Q_0$ and a tail $t(f) \in Q_0$. For example, $A_2$ in Section 3.2 is a quiver of the form $A_2 = (\{X, Y\}, \{X \xrightarrow{f} Y\})$, $t(f) = Y$ and $s(f) = X$.

Associated to any quiver $Q$, is the path algebra $kQ$ consisting of $k$-linear combinations of paths between the vertices in $Q$. Any two such paths $a, b \in kQ$ multiply by concatenation $ab$ when the vertex at which $a$ ends agrees with the vertex at which $b$ begins; the product is defined to be zero otherwise. The category of left modules over the path algebra $kQ$ is equivalent to the category of functors $Q\text{-mod} = \text{Hom}(Q, \text{Vect}_k)$ appearing in Section 3.2

$$kQ\text{-mod} \cong Q\text{-mod}.$$ 

Given a quiver $Q$, one may form another quiver $\overline{Q}$ which is obtained by adding a formal inverse $f^*: t(f) \to s(f)$ to each arrow $f: s(f) \to t(f)$. If the set of these arrows is denoted by $Q_1^*$ then $\overline{Q} = (Q_0, Q_1 \cup Q_1^*)$. Let $\rho$ be the element of the path algebra $k\overline{Q}$ given by the sum

$$\rho = \sum_{f \in Q_1^*} (ff^* - f^*f).$$

The preprojective algebra is the quotient of the path algebra of $\overline{Q}$ by the ideal generated by $\rho$:

$$\Pi Q = k\overline{Q}/(\rho).$$

Remark 4.1. The category $\Pi Q\text{-mod}$ is a kind of next-simplest most-interesting replacement for the category $Q\text{-mod}$, see [4] or [16, Thm. C].
Example 4.2. When $Q = A_n$ is the graph consisting of $n$ vertices $\{1, \ldots, n\}$ with one directed edge $(i, i+1): i \to i + 1$ for $1 \leq i < n$. Then the graph $A_n$ is formed by adding the inverses $(i, i+1)^* = (i+1, i): i+1 \to i$ pictured below.

Quotienting the path algebra $k\overline{A}_n$ by the ideal $(\rho)$, described above, implies the relations of the preprojective algebra

$$(i, i-1)(i-1, i) = (i, i+1)(i+1, i) \quad \text{for} \quad i = 2, \ldots, n-1,$$

$$(1, 2)(2, 1) = 0 \quad \text{and} \quad (n, n-1)(n-1, n) = 0.$$

These preprojective algebras are closely related to the algebras studied by Khovanov-Seidel: if $A_n^!$ denotes the Koszul dual of the Khovanov-Seidel algebra then the preprojective algebra is obtained by adding one relation

$$\Pi A_n = A_n^! / \langle (n, n-1)(n-1, n) \rangle,$$

see [11] and [15, §4].

4.1. The algebra $\Pi A_2$

In this section we will discuss the algebra $\Pi A_2$ and its representation theory in more detail.

Definition 4.3. The algebra $\Pi A_2$ may be thought of as a category with two objects $\text{Ob}(\Pi A_2) = \{1, 2\}$, each with its own identity map $1_1$ or $1_2$, and two maps $(12): 1 \to 2$ and $(21): 2 \to 1$ which satisfy two relations:

$$(12)(21) = 0 \quad \text{and} \quad (21)(12) = 0.$$  

The quiver underlying this construction is pictured below.

The representation theory of this algebra is well-known. The abelian category $\Pi A_2$-mod of finitely generated representations has four indecomposable modules: $S_1$, $S_2$, $P_1$ and $P_2$ [8, §8]. The first two modules $S_1$ and $S_2$ are 1-dimensional simple modules associated to the vertices 1 and 2,

$$S_1 = k(1) \quad \text{and} \quad S_2 = k(2),$$

where $(i)$ acts as the identity on $S_i$ and all other basis elements of $\Pi A_2$ act trivially. The second two modules are projective modules spanned by the set of paths which begin at their respective vertices

$$P_1 = \Pi A_2(1) \quad \text{and} \quad P_2 = \Pi A_2(2).$$

While there are no maps of degree zero between simple modules, the arrows $(12)$ and $(21)$ in the definition above induce maps $(12): P_1 \to P_2$ and $(21): P_2 \to P_1$ between
projective modules. Each of the two maps, indicated by bold arrows in the diagram below, has a kernel and image, which give the two maps between projectives and simples also pictured in the diagrams below.

There is an obvious symmetry implicit in the discussion above which we next record.

**Proposition 4.4.** There is an involution $\kappa : \Pi A_2\text{-mod} \to \Pi A_2\text{-mod}$ induced by exchanging the indecomposable modules

$$P_1 \leftrightarrow P_2 \quad \text{and} \quad S_1 \leftrightarrow S_2.$$

The two short exact sequences

$$0 \to S_1 \xrightarrow{j_2} P_2 \xrightarrow{p_2} S_2 \to 0 \quad \text{and} \quad 0 \to S_2 \xrightarrow{j_2} P_1 \xrightarrow{p_1} S_1 \to 0$$

correspond to two maps $\alpha : S_2 \to S_1$ and $\beta : S_1 \to S_2$ which span the groups $\text{Ext}^1(S_2, S_1)$ and $\text{Ext}^1(S_1, S_2)$, respectively.

There are projective resolutions $Q_i$ of simple modules $S_i$ by the projective modules $P_1$ and $P_2$

$$Q_i = [\cdots \to P_1 \xrightarrow{(12)} P_2 \xrightarrow{(21)} P_1 \to \cdots \to P_i] \xrightarrow{p_i} S_i \to 0.$$

The structure exhibited among the indecomposables of $\Pi A_2$ is a kind of double of the structure discussed in Section 3.2. In this paper we seek to understand what the $\Pi A_2$ analogue of $\Delta$ corepresents: a preprojective analogue of distinguished triangles and algebraic cones. In order to answer this question we construct an $A_\infty$-category analogue $\Pi$ of $\Delta$.

In more detail, we wish to understand the $\text{Ext}$-algebra of $M = S_1 \oplus P_1 \oplus P_2 \oplus S_2$. After replacing each simple $S_i$ with the projective resolution $Q_i$, and setting $\tilde{M} = Q_i \oplus P_1 \oplus P_2 \oplus Q_2$, Theorem 2.7, allows us to compute an $A_\infty$-structure on the $\text{Ext}$-algebra $\text{Ext}^*(\tilde{M})$ so that the dg category $\text{End}^*(\tilde{M})$ and $\text{Ext}^*(M)$ are $A_\infty$-equivalent.

$$\text{End}^*(\tilde{M}) \tilde{\to} \text{Ext}^*(M).$$

The $A_\infty$-category $\Pi = \text{Ext}^*(M)$ will serve as our replacement for $\Delta$ in what follows.

### 4.2. The category $\Pi$

As an $A_\infty$-category $\Pi$ has $m_1 = 0$. The generating maps of the category $\Pi$ are pictured as follows:
where \(|\alpha| = 1, |\beta| = 1\) and all other maps have degree 0.

**Remark 4.5.** All of the tables in this section are written so that the left column is equivalent to \(\kappa\) of the right column; \(\kappa\) is defined in Proposition 4.4.

Let \(u_1 := \alpha \beta\) and \(u_2 := \beta \alpha\) denote the degree 2 endomorphisms of \(S_1\) and \(S_2\) respectively. Then the composition

\[
m_2 : \text{Hom}(X_1, X_2) \otimes \text{Hom}(X_0, X_1) \to \text{Hom}(X_0, X_2), \quad f \otimes g \mapsto f \circ g
\]

is determined by the requirements of the identity maps and the table:

\[
\begin{align*}
m_2(j_1, p_2) &= (21), & m_2(j_2, p_1) &= (12), \\
m_2(u_1^n, u_1^m) &= u_1^{n+m}, & m_2(u_2^n, u_2^m) &= u_2^{n+m}, \\
m_2(\beta u_1^n, u_1^n) &= \beta u_1^{n+m}, & m_2(\alpha u_2^n, u_2^n) &= \alpha u_2^{n+m}, \\
m_2(u_2^n, \beta u_1^n) &= \beta u_1^{n+m}, & m_2(u_1^n, \alpha u_2^n) &= \alpha u_2^{n+m}, \\
m_2(\alpha u_2^n, \beta u_1^n) &= u_1^{n+m+1}, & m_2(\beta u_2^n, \alpha u_2^n) &= u_2^{n+m+1}.
\end{align*}
\]

In other words, all of the compositions are zero besides those involving identity maps, \(j_1p_2 = (21), j_2p_1 = (12)\) and the maps \(\alpha, \beta\) which generate a free subalgebra. Together with maps \(u_1 = \alpha \beta\) and \(u_2 = \beta \alpha\) there are relations

\[
u_2 \beta = \beta u_1 \quad \text{and} \quad u_1 \alpha = \alpha u_2.
\]

The generating set pictured above determines the basis for each \(\text{Hom}\)-space:

\[
\begin{align*}
\text{Hom}(P_1, S_1) &= p_1, & \text{Hom}(P_2, S_2) &= p_2, \\
\text{Hom}(S_1, P_2) &= j_2, & \text{Hom}(S_2, P_1) &= j_1, \\
\text{Hom}(P_1, P_2) &= (12), & \text{Hom}(P_2, P_1) &= (21), \\
\text{Hom}(P_1, P_1) &= 1_{P_1}, & \text{Hom}(P_2, P_1) &= 1_{P_2}, \\
\text{Hom}(S_1, S_1) &= u_1^n, & \text{Hom}(S_2, S_2) &= u_2^n, \\
\text{Hom}(S_1, S_2) &= \beta u_1^n, & \text{Hom}(S_2, S_1) &= \alpha u_2^n,
\end{align*}
\]

where \(n \geq 0\).

When \(d = 3\), the \(A_\infty\)-multiplication map

\[
m_3 : \text{Hom}(X_2, X_3) \otimes \text{Hom}(X_1, X_2) \otimes \text{Hom}(X_0, X_1) \to \text{Hom}(X_0, X_3)[-1]
\]

is determined by the constraints of strict unitality (see (2)) and the behavior of certain
triangles within the graph above under action of $m_2$. There are two basic triangles:

\[
\begin{align*}
(A) \quad & m_3(\alpha, p_2, j_2) = 1_{s_1}, \quad m_3(\beta, p_1, j_1) = 1_{s_2}, \\
& m_3(p_2, j_2, \alpha) = 1_{s_1}, \quad m_3(p_1, j_1, \beta) = 1_{s_2}, \\
& m_3(j_2, \alpha, p_2) = 1_{p_2}, \quad m_3(j_1, \beta, p_1) = 1_{p_1}
\end{align*}
\]

consisting of rotations of the upper and lower faces of the tetrahedron pictured above.

There is a trick to finding several other non-trivial $m_3$-products in $\Pi$. They are implied by the $A_\infty$-relations and the basic triangles above. Ignoring signs for a moment, the first $A_\infty$-relation, $d = 4$ in equation (1), to incorporate the $m_3$-operation is written in long form as follows:

\[
m_3(m_2(h, f_3), f_2, f_1) + m_3(h, m_2(f_3, f_2), f_1) + m_3(h, f_3, m_2(f_2, f_1)) + m_2(m_3(h, f_3, f_2), f_1) + m_2(h, m_3(f_3, f_2, f_1)) = 0. \tag{10}
\]

So when all but the first and last terms in the sum vanish, each face $m_3(f_3, f_2, f_1) = g$ of the tetrahedron above gives rise to a number of other $m_3$-operations. These can be constructed by using non-trivial $m_2$-compositions on either the left

\[
m_3(m_2(h, f_3), f_2, f_1) = m_2(h, m_3(f_3, f_2, f_1)) = m_2(h, g),
\]

or, by symmetry, on the right

\[
m_3(f_3, f_2, m_2(f_1, h)) = m_2(m_3(f_3, f_2, f_1), h) = m_2(g, h).
\]

Using this trick, each case (A) and (B) above gives the three additional compositions:

\[
\begin{align*}
(A) \quad & m_3(\alpha, p_2, (12)) = p_1, \quad m_3(\beta, p_1, (21)) = p_2, \\
& m_3(u_2^3, p_2, j_2) = \beta u_1^{n-1}, \quad m_3(u_1^0, p_1, j_1) = \alpha u_2^{n-1}, \\
& m_3(\alpha u_2^n, p_2, j_2) = u_1^n, \quad m_3(\beta u_1^n, p_1, j_1) = u_2^n, \\
(B) \quad & m_3(21), f_2, \alpha) = j_1, \quad m_3(12), j_1, \beta) = j_2, \\
& m_3(p_2, j_2, u_1^n) = \beta u_1^{n-1}, \quad m_3(p_1, j_1, u_2^n) = \alpha u_2^{n-1}, \\
& m_3(p_2, j_2, \alpha u_2^n) = u_2^n, \quad m_3(p_1, j_1, \beta u_1^n) = u_1^n.
\end{align*}
\]

When $d = 4$, the $A_\infty$-multiplication map

\[
m_4: Hom(X_3, X_4) \otimes Hom(X_2, X_3) \otimes Hom(X_1, X_2) \otimes Hom(X_0, X_1) \to Hom(X_0, X_4)[-2]
\]

is determined by the constraints of strict unitality (see equation (2)) and the behavior of certain triangles within the graph above under action of $m_2$. The two basic operations below correspond to the left and right faces of the tetrahedron on the page pictured above:

\[
\begin{align*}
(A) \quad & m_4(p_1, (21), j_2, u_1) = 1_{s_1}, \quad m_4(p_2, (12), j_1, u_2) = 1_{s_2}, \\
& m_4(u_1, p_1, (21), j_2) = 1_{s_1}, \quad m_4(u_2, p_2, (12), j_1) = 1_{s_2}, \\
& m_4(j_2, u_1, p_1, (21)) = 1_{p_2}, \quad m_4(j_1, u_2, p_2, (12)) = 1_{p_1}, \\
& m_4((21), j_2, u_1, p_1) = 1_{p_1}, \quad m_4((12), j_1, u_2, p_2) = 1_{p_2}.
\end{align*}
\]

As explained for the $m_3$-operations above, due to the vanishing of some terms in the $A_\infty$-relation for the $m_4$-operation, we can act with the $m_2$-operation on either the
then we compute all of the compositions of maps corresponding to these homotopies. We now define certain important maps in what follows below, the following notation

\[ f_1, \ldots, f_n \]

Remark 4.6. Intuitively speaking, if we view the input of an \( m_n \)-operation \( m_n(f_n, \ldots, f_1) \) as a path \( f_1, \ldots, f_n \) in the graph featured at the beginning of Section 4.2 then the higher \( A_\infty \)-operations that we find can be seen as extensions of the lower order operations discussed above. Each of these extensions is formed by adding a loop of the form \( (12) \) or \( (21) \) to the path while balancing the grading by adding a loop of the form \( u_1 = \alpha \beta \) or \( u_2 = \beta \alpha \). The equations above list the ways in which the loops \((12)\) or \((21)\) can be added. See Remark 4.8.

This classification result is accomplished by Theorem 4.7, which is a computation using homotopy perturbation theory (Theorem 2.7). We need to introduce a few more preliminaries before proceeding to the theorem.

Our goal in Theorem 4.7 is to compute all of the compositions of maps corresponding to the decorated binary trees discussed in Section 2.2. The key is to construct homotopies \( h \)-maps for compositions which are nullhomotopic and study compositions of these homotopies. We now define certain important maps in \( End^*(\tilde{M}) \). In what follows below, \( i \in \mathbb{Z}/2 \).

Below is the map \( h_{S_i S_i}^{(n)}: S_i \to S_i[-2n] \).

\[
\begin{align*}
&\cdots \longrightarrow P_i \longrightarrow P_{i+1} \longrightarrow P_i \\
&\quad \downarrow_{1} \quad \downarrow_{1} \quad \downarrow_{1} \\
&\cdots \longrightarrow P_i \longrightarrow P_{i+1} \longrightarrow P_{i+1} \longrightarrow \cdots \longrightarrow P_{i+1} \longrightarrow P_i
\end{align*}
\]
Below is the map $h^{(n)}_{S_i,S_{i+1}}: S_{i+1} \to S_i[-2n - 1]$.

\[
\cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \\
\downarrow 1 \downarrow 1 \downarrow 1 \\
\cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow \cdots \rightarrow P_{i+1} \rightarrow P_i
\]

Below is the map $h^{(n)}_{S_i,P_i}: P_i \to S_i[-2n]$.

\[
P_i \\
\downarrow 1 \\
\cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow \cdots \rightarrow P_i
\]

Below is the map $h^{(n)}_{S_i,P_{i+1}}: P_{i+1} \to S_i[-2n - 1]$.

\[
P_{i+1} \\
\downarrow 1 \\
\cdots \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_i
\]

Below is the map $h^{(n)}_{P_i,S_i}: S_i \to P_i[2n]$.

\[
\cdots \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_i \\
\downarrow 1 \\
P_{i+1}
\]

Below is the map $h^{(n)}_{P_{i+1},S_i}: S_i \to P_{i+1}[2n + 1]$.

\[
\cdots \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_i \\
\downarrow 1 \\
P_i
\]

The trees appearing in (4) propagate from leaves to root. The homotopies appear in order determined by distance from the leaves. The initial homotopies $H$ arise as follows:

\[
H(p_1j_1) = h_{S_1S_2}^{(0)}, \quad H(p_2j_2) = h_{S_2S_1}^{(0)}, \\
H(j_1(\beta u_1^n)) = h_{P_1S_1}^{(n)}, \quad H(j_2(\alpha u_1^n)) = h_{P_2S_1}^{(n)}, \\
H(p_1(21)) = h_{S_1P_2}^{(0)}, \quad H(p_2(12)) = h_{S_2P_1}^{(0)}, \\
H(j_2u_1^n) = h_{P_2S_1}^{(n-1)}, \quad n > 0, \quad H(j_1u_2^n) = h_{P_1S_2}^{(n-1)}, \quad n > 0.
\]

(12)

“Higher” $h$-maps arise by applying $H$ to these initial $h$ maps as follows:
\[ H(h_{S_2}^{(n)} \circ j_2) = h_{S_2 S_2}^{(n+1)}, \quad n \geq 0, \]
\[ H(h_{S_2}^{(n)} \circ (12)) = h_{S_2}^{(n+1)}, \quad n \geq 0, \]
\[ H(h_{S_1}^{(n)} \circ j_1) = h_{S_1 S_1}^{(n)}, \quad n \geq 1, \]
\[ H(h_{S_2}^{(n)} \circ j_2) = h_{S_2 S_1}^{(n)}, \quad n \geq 1, \]
\[ H(h_{S_1}^{(n)} \circ (21)) = h_{S_1}^{(n+1)}, \quad n \geq 1, \]
\[ H((12) \circ h_{P_2 S_1}^{(n)}) = h_{P_2 S_1}^{(n+1)}, \quad n \geq 1, \]
\[ H((21) \circ h_{P_2 S_1}^{(n)}) = h_{P_2 S_1}^{(n+1)}, \quad n \geq 0. \]

Compositions of \( h \)'s with elements in the \( \text{Ext} \)-algebra and other \( h \)'s produce the elements in the \( \text{Ext} \)-algebra listed below. The map \( H \) is zero on any element \( f \) representing a cycle in the \( \text{Ext} \)-algebra:

\[
\begin{align*}
    u_1^n \circ h_{S_1 S_2}^{(m)} &= u_1^n u_2^{n-m-1} \alpha, & u_2^n \circ h_{S_1 S_2}^{(m)} &= u_1^n u_2^{n-m-1} \beta, \\
    u_2^n \beta \circ h_{S_1 S_2}^{(m)} &= u_2^n, & u_2^n \alpha \circ h_{S_1 S_2}^{(m)} &= u_2^n, \\
    h_{P_2 S_1}^{(0)} \circ p_1 &= 1_{P_1}, & h_{P_2 S_2}^{(0)} \circ p_2 &= 1_{P_2}, \\
    (12) \circ h_{P_2 S_1}^{(0)} &= j_2, & (21) \circ h_{P_2 S_2}^{(0)} &= j_1, \\
    u_2^n \beta \circ h_{S_1 S_2}^{(n)} &= \delta_{m,n} p_2, & u_2^n \alpha \circ h_{S_1 S_2}^{(n)} &= \delta_{m,n} p_1, \\
    h_{P_2 S_1}^{(0)} \circ h_{S_1 S_1}^{(n)} &= \delta_{m,n} p_1, & h_{P_2 S_2}^{(0)} \circ h_{S_1 S_1}^{(n)} &= \delta_{m,n} p_2, \\
    u_2^n \beta \circ h_{S_1 S_1}^{(n)} &= u_2^n, & u_2^n \alpha \circ h_{S_1 S_1}^{(n)} &= u_2^n, \\
    h_{P_2 S_2}^{(i)} \circ h_{S_1 S_1}^{(n)} &= \delta_{m,n} 1_{P_2}, & h_{P_2 S_1}^{(j)} \circ h_{S_1 S_1}^{(n)} &= \delta_{m,n} 1_{P_1},
\end{align*}
\]

where \( \delta_{m,n} \) is the Kronecker delta. We also have the following list of “partial” terminating operations. Let \( \gamma_1 = \alpha, \gamma_2 = \beta \) and let \( i \in \mathbb{Z}/2 \). These compositions are not cycles, so the map \( H \) is defined to be zero on them.

Below is the map \( h_{S_1 S_1}^{(n)} \circ u_1^k \).

\[ \cdots \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow \cdots \rightarrow P_i \]
\[ \quad \downarrow^1 \downarrow^1 \downarrow^1 \]
\[ \cdots \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_{i+1} \rightarrow P_i \]

Below is the map \( h_{S_1 S_1}^{(n)} \circ u_1^k \gamma_1 \).

\[ \cdots \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow \cdots \rightarrow P_{i+1} \]
\[ \quad \downarrow^1 \downarrow^1 \downarrow^1 \]
\[ \cdots \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_{i+1} \rightarrow P_i \]

Below is the map \( h_{S_1 S_{i+1}}^{(n)} \circ u_1^k \gamma_{i+1} \).

\[ \cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_{i+1} \]
\[ \quad \downarrow^1 \downarrow^1 \downarrow^1 \]
\[ \cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_{i+1} \rightarrow P_i \]
Below is the map $h_{S_i S_{i+1}}^{(n)} \circ u_{i+1}^{k} \gamma_{i+1}$.

\[ \cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_i \]

\[ \cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow \cdots \rightarrow P_i \rightarrow P_i \]

Below is the map $h_{S_i P_{i+1}}^{(n)} \circ h_{P_{i+1} S_i}^{(k)}$.

\[ \cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_i \]

\[ \cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow \cdots \rightarrow P_{i+1} \rightarrow P_i \]

Below is the map $h_{S_i P_i}^{(n)} \circ h_{P_i S_i}^{(k)}$.

\[ \cdots \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow \cdots \rightarrow P_i \]

\[ \cdots \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_{i+1} \rightarrow P_i \]

Below is the map $p_i \circ h_{P_i S_i}^{(k)}$.

\[ \cdots \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow \cdots \rightarrow P_i \]

\[ \cdots \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_{i+1} \rightarrow P_i \]

Below is the map $h_{S_{i+1} P_{i+1}}^{(n)} \circ h_{P_{i+1} S_i}^{(k)}$.

\[ \cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_i \]

\[ \cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow \cdots \rightarrow P_i \rightarrow P_{i+1} \]

Below is the map $p_{i+1} \circ h_{P_{i+1} S_i}^{(k)}$.

\[ \cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_i \]

\[ \cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_i \rightarrow \cdots \rightarrow P_{i+1} \rightarrow P_i \]

Below is the map $h_{S_i P_{i+1}}^{(n)} \circ h_{P_{i+1} S_{i+1}}^{(k)}$.

\[ \cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_{i+1} \]

\[ \cdots \rightarrow P_{i+1} \rightarrow P_i \rightarrow P_{i+1} \rightarrow P_{i+1} \rightarrow \cdots \rightarrow P_{i+1} \rightarrow P_i \]
Theorem 4.7. All of the non-trivial operations for $\Pi$ are given by the list below once combined with the corresponding list obtained by applying the automorphism $\kappa$ (Proposition 4.4) which exchanges the nodes 1 and 2 in the underlying quiver.

This list contains the $m_2$ operations:

$$m_2(j_1, p_2) = (21),$$
$$m_2(u_1^n, u_1^m) = u_1^{n+m},$$
$$m_2(\beta u_1^n, u_1^m) = \beta u_1^{n+m},$$
$$m_2(u_2^n, \beta u_1^m) = \beta u_1^{n+m},$$
$$m_2(\alpha u_2^n, \beta u_1^m) = u_1^{n+m+1}.$$

This list contains the higher operations:

$$m_{2n+2k+3}((12), (212)^k, j_1, \beta u_1^{n+k+1}, p_1, (212)^n, (21)) = 1_{p_2},$$
$$m_{2n+3}((12), (212)^n, j_1, \beta u_1^1) = j_2,$$
$$m_{2n+3}((212)^k, j_1, \beta u_1^n, p_1, (212)^n-k) = 1_{p_1},$$
$$m_{2n+3}(u_1^k, p_1, (212)^n, j_1) = u_1^{k-n-1},$$
$$m_{2n+4}(u_1^k, p_1, (212)^n, (21), j_2) = u_1^{k-n-1},$$
$$m_{2n+4}(p_1, (212)^n, (21), j_2, u_1^1) = u_1^{k-n-1},$$
$$m_{2n+4}(u_1^2, \beta, p_1, (212)^n, (21), j_2) = u_2^{k-n-1} \beta,$$
$$m_{2n+3}(u_1^2, \beta, p_1, (212)^n, (21)) = p_2,$$
$$m_{2n+2}(u_1^n, p_1, (212)^n) = p_1,$$
$$m_{2k+2n+4}((121)^{2k}, j_2, u_1^{n+k+1}, p_1, (212)^n, (21)) = 1_{p_2},$$
$$m_{2n+4}((121)^{n+1}, j_2, u_1^{n+1}) = j_2,$$
$$m_{2n+4}((212)^k, (21), j_2, u_1^n, p_1, (212)^n-k) = 1_{p_1},$$
$$m_{2m+3}(p_2, (121)^{2m}, j_2, \alpha u_2^2) = u_2^{n-m},$$
$$m_{2m+3}(p_2, (121)^{m}, j_2, u_1^n) = \beta u_1^{n-(m+1)},$$
$$m_{2m+4}(p_1, (21), (121)^{2m}, j_2, \alpha u_2^{m+1}) = \alpha u_2^{n-m}.$$

Proof. The $A_{\infty}$-structure on $\Pi$ is determined by the dg structure on $End^*(\tilde{M})$ and Theorem 2.7. The dg category $End^*(\tilde{M})$ only has only non-trivial first and second multiplications (the derivation and the natural algebra multiplication). See Example 2.4 for more details.

Since all of the higher multiplications in $End^*(\tilde{M})$ are trivial, in order to compute $m_n$ we must determine all possible binary trees with $n$ input edges satisfying certain properties. Let $f_n, \ldots, f_1 \in \Pi$ such that the composition $f_{i+1} \circ f_i$ makes sense for $i = 1, \ldots, n-1$. The input edges (read from left to right) are labeled $f_n, \ldots, f_1$. First one includes each $f_i \in \Pi$ into $End^*(\tilde{M})$. The internal edges are labeled by $H$.

From a calculation we see that $H(f_{i+1} \circ f_i)$ for $f_{i+1}, f_i \in \Pi$ is non-zero only in the cases listed in (12).

From a calculation we see that higher homotopy maps are produced only when $H$ is applied to a product of the form $hf$ or $fh$ where $h$ is some higher homotopy map and $f$ is an element in $\Pi = Ext^*(\tilde{M})$. The possibilities are listed in (13). In particular, the only non-zero way to grow a binary tree labeled as in Section 2.2 is illustrated in the remark below.

Finally, to produce an element in $\Pi$, one must apply the projection map $p$ described in (3) to certain products of two elements of $End^*(\tilde{M})$ listed in (14).
Any other composition that we need to consider produces a non-cycle and so $H$ of it is set to zero. These cases are enumerated above as partial terminating operations.

**Remark 4.8.** The $A_\infty$-maps $m_2$ are determined by the composition in the $\text{Ext}$-algebra. The maps $m_3$ and $m_4$ can be done by hand. The only way to inductively evolve a binary tree to give non-zero higher operation is illustrated below, see Remark 4.6.

![Diagram](image)

**4.3. The preprojective cone**

Recall from Definition 3.7 that our abstract cones are determined by a certain lifting problem. This section combines all of the bits and pieces from previous sections and provides some explanation as to what we have computed.

Before proceeding, it is useful to observe the following remark.

**Remark 4.9.** If $F: \mathcal{C} \to \mathcal{D}$ is an $A_\infty$-functor such that $F^d = 0$ for $d \geq 2$, then the $A_\infty$-relation in Definition 2.5 becomes

$$m^D_d(F^1(f_d), \ldots, F^1(f_1)) = F^1(m^C_d(f_d, \ldots, f_1)).$$

The proposition below is a detailed version of the comments at the end of Example 3.10 in the preprojective setting.
Proposition 4.10. The subcategory $\pi$ associated to the two simple modules $S_1, S_2 \in \Pi A_2\text{-mod}$

\[
\begin{array}{ccc}
S_1 & \xrightarrow{\alpha} & S_2 \\
\downarrow{\beta} & & \\
& & \\
\end{array}
\]

is formal; the higher $A_\infty$-structure $m_d^{\pi} = 0$ for $d > 2$. The inclusion $\iota: \pi \hookrightarrow \Pi$ is an $A_\infty$-functor $\iota = \{\iota^d\}$ which is determined by the assignments: $\iota(S_i) := S_i$ on objects, $\iota^1(\alpha) := \alpha$, $\iota^1(\beta) := \beta$ on maps and $\iota^d := 0$ for $d \geq 2$.

Proof. The category $\pi$ is formal by Theorem 4.7 since there are no non-trivial higher operations in the list involving only entries of the form $\alpha$ and $\beta$. Since $\pi$ is formal, we need only check that $\iota$ satisfies equation (15). This again follows from the observation that there are no relations among $\alpha$ and $\beta$ in $\Pi$ and there are no higher $A_\infty$-relations, $m_d^{\iota} \equiv 0$ for $d > 2$, by Theorem 4.7.

In the notation introduced by the proposition, the lifting problem in Definition 3.7 can be restated by the commutative diagram

\[
\begin{array}{ccc}
\pi & \xrightarrow{F} & \mathcal{D} \\
\downarrow{\iota} & & \\
\Pi & \xrightarrow{\tilde{F}} & \\
\end{array}
\]

So the initial data is an $A_\infty$-functor $F: \pi \to \mathcal{D}$ and a cone on $F$ is determined by a lift along $\iota$, i.e. an $A_\infty$-functor $\tilde{F}: \Pi \to \mathcal{D}$ for which $\tilde{F} \circ \iota \simeq F$ in the category $A_\infty(\pi, \mathcal{D})$.

The theorem below shows that the upper and lower parts of the $\Pi$-diagram at the beginning of Section 4.2 are triangles in the sense of Theorem 3.6. It follows that, up to homotopy, the portions of the category in the completion, $\tilde{F}(P_1)$ and $\tilde{F}(P_2)$, are classical cones on the maps $F^1(\beta)$ and $F^1(\alpha)$, respectively.

Theorem 4.11. If $F: \Pi \to \mathcal{D}$ is an $A_\infty$-functor from the preprojective category to an $A_\infty$-category $\mathcal{D}$ then the objects associated to $P_i$ in $\mathcal{D}$ are homotopy equivalent to cones on the maps $\alpha$ and $\beta$. More precisely,

\[
F(P_1) \simeq C(F^1(\beta)) \quad \text{and} \quad \text{F}(P_2) \simeq C(F^1(\alpha)).
\] (16)

Proof. The category $\Delta$ is pictured in Definition 3.5. There are three objects $A, B$ and $C$ together with maps $\alpha: A \to B$, $\beta: B \to C$ and $\gamma: C \to A$ with degrees $|\alpha| = 0$, $|\beta| = 0$ and $|\gamma| = 1$.

For $i = 1, 2$, there are assignments $\iota_i: \text{Ob}(\Delta) \hookrightarrow \text{Ob}(\Pi)$ and $\iota_i: \text{Hom}_{\Delta}(X_1, X_0) \to \text{Hom}_{\Pi}(\iota_i(X_1), \iota_i(X_0))$ given by

\[
\begin{array}{c|ccc|}
\text{ } & A & B & C \\
\hline
i_1 & S_2 & P_1 & S_1 \\
\hline
i_2 & S_1 & P_2 & S_2 \\
\end{array}
\quad \text{and} \quad
\begin{array}{c|ccc|}
\alpha & \beta & \gamma \\
\hline
i_1 & j_1 & p_1 & \beta \\
\hline
i_2 & j_2 & p_2 & \alpha \\
\end{array}
\]

Set $\iota^d_i := 0$ for $d \geq 2$. In order to see that the assignments $\iota_i$ are $A_\infty$-functors, we must check that the $A_\infty$-relation equation (15) above is satisfied. The cases $\iota_1$ and $\iota_2$
are symmetric. So consider \( \iota_1 \), then equation (15) holds because the only non-identity compositions are zero

\[
j_1 \circ \beta = 0 \quad p_1 \circ j_1 = 0 \quad \beta \circ p_1 = 0
\]

and the only higher \( A_\infty \)-operation supported by the morphisms \( \{ p_1, j_1, \beta \} \) in \( \Pi \) are given by the \( m_3 \) in equation (9); these agree with equation (7).

Thus the restrictions formed by the compositions \( F \circ \iota_i : \Delta \to \mathcal{D} \) are \( A_\infty \)-functors. By Theorem 3.6, each of the two restrictions determines a triangle in \( \mathcal{D} \). In particular, the image of each vertex of \( \Delta \subset \Pi \) must be homotopic to the cone on the morphism in subcategory complementary to the vertex. A special case of this is equation (16).

\textit{Example 4.12.} Suppose we have an \( A_\infty \)-functor \( F : \pi \to \mathcal{D} \). The structure maps \( F : \text{Ob}(\pi) \to \text{Ob}(\mathcal{D}) \) and \( F_{1, Y}^X : \text{Hom}_\pi(X, Y) \to \text{Hom}_\mathcal{D}(F(X), F(Y)) \) determine two cycles

\[
S'_1 \xrightarrow{\alpha'} S'_2,
\]

where \( S'_1 = F(S_1) \), \( S'_2 = F(S_2) \), \( \alpha' = F^1(\alpha) \) and \( \beta' = F^1(\beta) \). If \( \mathcal{D} \) is triangulated then there are objects \( C(\alpha') \) and \( C(\beta') \) in \( \mathcal{D} \) which are cones in the sense of Definition 3.4. By the theorem above, a lift \( \tilde{F} : \Pi \to \mathcal{D} \) of \( F \) along \( \iota \) must associate to \( P_1 \) and \( P_2 \) objects which are homotopy equivalent to \( C(\beta') \) and \( C(\alpha') \) respectively. When \( \mathcal{D} \) is a dg category of complexes, this can be made very explicit. The diagram for \( \Pi \) at the beginning of Section 4.2 becomes

\[
\begin{array}{c}
\text{(1, 0)}^t \\
\alpha' \\
\text{(1, 0)} \\
\beta' \\
\text{(0, 1)}^t \\
\text{(0, 1)} \\
\end{array}
\]

\[
\begin{array}{c}
(S'_1 \oplus S'_2[1], d_{C(\alpha')}) \\
(1, 0)^t \\
(0, 1) \\
(1, 0) \\
(0, 1)^t \\
(S'_1[1] \oplus S'_2, d_{C(\beta')})
\end{array}
\]

Since \( (21) = j_1 \circ p_2 \) and \( (12) = j_2 \circ p_1 \), the matrices associated to these maps are

\[
(21) = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \quad \text{and} \quad (12) = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}
\]

and we see directly the relations \((12)(21) = 0\) and \((21)(12) = 0\).

\textbf{4.4. Coda}

The remainder of this paper establishes some context which pertains to future work.

\textit{Remark 4.13.} Just as Proposition 4.10 shows that the subcategory \( \pi \) determined by simples embeds in \( \Pi \), the quiver presentation for \( \Pi A_2 \) in Definition 4.3 embeds in \( \Pi \).
by the Yoneda embedding. So for $\Pi$, there are two notions of map which yield the same notion of a $\iota$-distinguished triangle. One comes from the $\alpha$ and $\beta$ maps between simple modules, and another comes from the $(21)$ and $(12)$ maps between projective modules. These two are dual in the sense that some of the data arising from a $\iota$-distinguished triangle of one $\iota$-cone construction is the same as the initial data for the other. Since exchanging simples and projectives results only in a rotation of the triangle in the construction of the $A_\infty$-cone, this shows that the preprojective cones exhibit some new behavior.

Remark 4.14. The simplicity of Theorem 4.11 seems incongruous with the complexity of the $A_\infty$-structure found in Theorem 4.7. The $A_\infty$-structure is complicated in part because of the trick in equation (10) and in part because it is recording higher Postnikov systems among compositions of $\alpha$ and $\beta$ maps. We will give an informal explanation of the first non-trivial example.

Recall from Section 3.1 that functors $\Delta \to \mathcal{D}$ correspond to distinguished triangles in $\mathcal{D}$ and that $\Delta$ agrees with the partially wrapped Fukaya category $F_3$ of the disk with three marked points. There is an extension of these statements.

Definition 4.15. The partially wrapped Fukaya category $F_n$ of the disk $D^2$ with $n$ marked points along the boundary is the $A_\infty$-category with $n$-objects $\text{Ob}(F_n) = \{X_i\}_{i \in \mathbb{Z}/n}$ and maps $1_{X_i} : X_i \to X_i$ and $f_1 : X_i \to X_{i+1}$. The gradings are chosen to satisfy the constraint $\sum |f_i| = n - 2$. The only non-trivial $A_\infty$-operations are compositions with identity and cyclic permutations of

$$m_n(f_1, \ldots, f_i) = 1_{X_i}.$$

See [9, above Eqn. (3.21)], [14, 5] or other references [17, I (3g) Rmk. 3.11]. For $n \geq 3$, functors from the partially wrapped Fukaya category $F_n \to \mathcal{D}$ correspond to $n$-fold extensions among objects in $\mathcal{D}$. Since there is a Morita equivalence $F_n \downarrow_{i,j} F_m \sim \rightarrow F_{n+m-2}$ associated to the gluing of the $i$th boundary object in $(D^2, n)$ to the $j$th boundary object in $(D^2, m)$ [9, §3.6], functors $F_n \to \mathcal{D}$ correspond to $n$-fold extensions among objects in $\mathcal{D}$ since every disk with $n$ marked points can be subdivided into a gluing of disks with $3$ marked points. On the other hand, precisely the same logic as was used in Theorem 4.11 to establish the existence of functors $(for i = 1, 2) i_i : \Delta \to \Pi$ for the triangles formed by the maps $\{j_1, p_1, \beta\}$ and $\{j_2, p_2, \alpha\}$ corresponding to $A_\infty$-operations in equation (9) can be used to establish the existence of $A_\infty$-functors $\kappa_i : F_4 \to \Pi$ for the quadrilaterals corresponding to the $\{p_1, (21), j_2, u_1\}$ and $\{p_2, (12), j_1, u_2\}$ appearing in equation (11). So in addition to determining two distinguished triangles:

$$\cdots \to S_1' \xrightarrow{\beta'} S_2' \to C(\beta') \to S_1'[1] \to \cdots$$

and

$$\cdots \to S_2' \xrightarrow{\alpha'} S_1' \to C(\alpha') \to S_2'[1] \to \cdots$$

as in Theorem 4.11 earlier, an $A_\infty$-functor $\tilde{F} : \Pi \to \mathcal{D}$ corresponding to a cone on $F : \pi \to \mathcal{D}$ determines $4$-fold Postnikov systems via restrictions $\tilde{F}\kappa_i : F_4 \to \mathcal{D}$. For
the maps \( \{p_2,(12),j_1,u_2\} \) this corresponds to

\[
\cdots \to C(\beta') \xrightarrow{(12)'} C(\alpha') \xrightarrow{p'_2} S'_2u'_2 S'_2[2] \to \cdots,
\]

where \((12)'_F = \tilde{F}^1(12), p'_2 = \tilde{F}^1(p_2)\) and \(u'_2 = \tilde{F}^1(u_2)\). Topologically the quadrilateral formed by the gluing of the two triangles below along the object \(S'_1\).

We conclude with a connection between the \(A_\infty\)-category \(\Pi\) and an important category coming from symplectic topology. The wrapped Fukaya category \(D^2W(P)\) of the pair of pants \(P = S^2 \setminus \{D^2_1, D^2_2, D^2_3\}\) can be generated by three Lagrangians \(X_0, X_1\) and \(X_2\). The \(A_\infty\)-subcategory \(A\) determined by these objects was studied in relation to the homological mirror symmetry conjecture \([2]\). Proposition 4.19 constructs a functor from this category to a version of the preprojective category \(\Pi'\).

**Definition 4.16** \([2]\). The generating category \(A\) has objects \(\text{Ob}(A) = \{X_0, X_1, X_2\}\) and morphisms

\[
\text{Hom}_A(X_i, X_j) = \begin{cases} 
 k[x_i, y_i]/(x_iy_i) & i = j, \\
 k[x_{i+1}]u_{i,i+1} = u_{i,i+1}k[y_i] & j = i + 1, \\
 k[y_{i-1}]v_{i,i-1} = v_{i,i-1}k[x_i] & j = i - 1, \\
 0 & \text{otherwise}.
\end{cases}
\]

These maps compose according to

\[
(x^k u_{i-1}, i) \circ (v_{i-1} x^l i) = x^{k+l+1} 
\]

and are graded by setting \(|u_{0,1}| = 1, |v_{1,0}| = 1\) and \(|u_{i,i+1}| = 0, |v_{i,i-1}| = 0\) in all other cases. This is pictured on the left-hand side of (19). The higher \(A_\infty\)-operations are determined by

\[
\begin{align*}
 m_3(u_2,0, u_1,2, u_0,1) = 1_{X_0}, & \quad m_3(v_1,0, v_2,1, v_0,2) = 1_{X_0}, \\
 m_3(u_0,1, u_2,0, u_1,2) = 1_{X_1}, & \quad m_3(v_2,1, v_0,2, v_1,0) = 1_{X_1}, \\
 m_3(u_1,2, u_0,1, u_2,0) = 1_{X_2}, & \quad m_3(v_0,2, v_1,0, v_2,1) = 1_{X_2}.
\end{align*}
\]

In order to make \(\Pi\) look like \(A\) in Definition 4.16, we need to combine the two projective objects \(P_1\) and \(P_2\) into one by forming the direct sum \(P := P_1 \oplus P_2\). The following definition recalls how direct sums are formed. This is a special case of additivization \([17, I (3k)]\).
Definition 4.17. If \( X, Y \in \text{Ob}(\mathcal{A}) \) are objects in an \( A_\infty \)-category \( \mathcal{A} \) then the direct sum \( X \oplus Y \in D^r(\mathcal{A}), [17, 1(4b)] \), satisfies
\[
\text{Hom}(X \oplus Y, Z) = \text{Hom}(X, Z) \oplus \text{Hom}(Y, Z),
\]
\[
\text{Hom}(W, X \oplus Y) = \text{Hom}(W, X) \oplus \text{Hom}(W, Y),
\]
and the \( A_\infty \)-operations extend additively
\[
m_k(a_k, \ldots, (a_i, a_i'), \ldots, a_1) = m_k(a_k, \ldots, a_i, \ldots, a_1) + m_k(a_k, \ldots, a_i', \ldots, a_1).
\]

This allows one to define an \( A_\infty \)-category \( \text{Mat}(\mathcal{A}) \) of direct sums of objects of \( \mathcal{A} \). The new category \( \Pi' \) is formed by combining the two projectives.

Definition 4.18. The category \( \Pi' \) is the full \( A_\infty \)-subcategory of \( \text{Mat}(\Pi) \) formed by the objects \( \{S_1, S_2, P\} \) where \( P := P_1 \oplus P_2 \). The \( A_\infty \)-structure of \( \Pi' \) is determined by Theorem 4.7 and Definition 4.17 above. The objects and morphisms in \( \Pi' \) are pictured on the right-hand side of (19).

\[
\begin{array}{c}
X_0 & \overset{v_{1,0}}{\leftarrow} & X_1 \\
\downarrow u_{0,1} & & \downarrow u_{1,2} \\
X_2 & \overset{v_{0,2}}{\leftarrow} & X_1 \\
\downarrow u_{2,0} & & \downarrow v_{2,1} \\
S_1 & \overset{\alpha}{\leftarrow} & S_2 \\
\downarrow p_1 & & \downarrow j_1 \\
P & \overset{j_2}{\leftarrow} & j_2 \\
\end{array}
\]

(19)

Proposition 4.19. There is a canonical \( A_\infty \)-functor \( G: \mathcal{A} \to \Pi' \).

Proof. The \( A_\infty \)-functor \( G = \{G^d\} \) is defined by mapping the left-hand side of the diagram above to the right-hand side of the diagram. In more detail, define \( G: \text{Ob}(\mathcal{A}) \to \text{Ob}(\Pi') \) by setting \( G(X_0) := S_1, G(X_1) := S_2 \) and \( G(X_2) := P \). The map \( G^1: \text{Hom}_A(X_i, X_j) \to \text{Hom}_{\Pi'}(G(X_i), G(X_j)) \) is determined by setting
\[
G^1(u_{0,1}) := \beta, \quad G^1(v_{1,0}) := \alpha, \\
G^1(u_{1,2}) := j_1, \quad G^1(v_{2,1}) := p_2, \\
G^1(u_{2,0}) := p_1, \quad G^1(v_{0,2}) := j_2,
\]
and the observation that equation (17) implies that the maps \( u_{i,i+1} \) and \( v_{i,i-1} \) for \( i \in \mathbb{Z}/3 \) generate \( \mathcal{A} \).

Since the higher maps \( G^d := 0 \) vanish for \( d \geq 2 \) then we need only check equation (15). The only non-trivial \( A_\infty \)-operations \( m_n \) for \( n > 2 \) in \( \mathcal{A} \) are determined by equation (18), however, equation (20) can be used to translate back and forth between equations (18) and (9). This shows that \( G \) satisfies equation (15) for all of the \( A_\infty \)-operations \( m_n \) for \( n \geq 3 \).

When \( n = 2 \), equation (15) means that \( G^1 \) is a homomorphism. The only relation in \( \mathcal{A} \) is \( x_iy_i = 0 \) in \( \text{End}(X_i) \) for \( i = 0, 1, 2 \). Equation (17), shows that
\[
x_i = u_{i-1,i}v_{i,i-1} \quad \text{and} \quad y_i = v_{i+1,i}u_{i,i+1}
\]
in \( \mathcal{A} \). Combining this with equation (20) gives
\[ x_0 = u_{2,0}v_{2,0} \mapsto p_1j_2 = 0, \quad y_0 = v_{1,0}u_{0,1} \mapsto \alpha \beta = u_1, \]
\[ x_1 = u_{0,1}v_{1,0} \mapsto \beta \alpha = u_2, \quad y_1 = v_{2,1}u_{1,2} \mapsto p_2j_1 = 0, \]
\[ x_2 = u_{1,2}v_{2,1} \mapsto j_1p_2 = (21), \quad y_2 = v_{0,2}u_{2,0} \mapsto j_2p_1 = (12). \]

Finally, using this calculation we check that \( x_iy_i = y_ix_i = 0 \):

\[ x_0y_0 \mapsto 0u_1 = 0, \quad y_0x_0 \mapsto u_10 = 0, \]
\[ x_1y_1 \mapsto u_20 = 0, \quad y_1x_1 \mapsto 0u_2 = 0, \]
\[ x_2y_2 \mapsto (21)(12) = 0, \quad y_2x_2 \mapsto (12)(21) = 0. \]
