pajansen@email.arizona.edu

Abstract

This work presents COSSAT, an intuitive constraint satisfaction solver and interpreted language for knowledge bases of semi-structured tables expressed as text. The stand-alone COSSAT solver allows easily expressing complex compositional “inference patterns” for how knowledge from different tables tends to connect to support inference and explanation construction in question answering and other downstream tasks, while including advanced declarative features and the ability to operate over multiple representations of text (words, lemmas, or part-of-speech tags). COSSAT also includes a hybrid imperative/declarative interpreted language for expressing simple models through minimally-specified simulations grounded in constraint patterns, helping bridge the gap between question answering, question explanation, and model simulation. The solver and interpreter are released as open source.¹

1 Introduction

Performing inference for complex question answering typically requires combining multiple facts from a knowledge base to arrive at a correct answer, where this set of facts can then be used to generate detailed human-readable explanations for the reasoning behind those answers. Combining multiple facts to perform natural language inference is extremely challenging, with contemporary methods generally unable to reliably combine more than two facts together. This is a significant limitation, as even elementary science questions require an average of six (and, as many as 16) atomic facts to answer and explain (Jansen et al., 2018; Xie et al., 2020) – particularly when those explanations include detailed world knowledge. For example,

¹Demo: https://youtu.be/t93Acsz7LyE
acting on those assertions. While logical methods provide provably correct inference and detailed explanations, these methods tend to be brittle in practice (MacCartney and Manning, 2007). At the other end of the formality continuum are inference methods that use unstructured text as knowledge (modeled at the level of the word (Fried et al., 2015), sentence (Valentino et al., 2020), or paragraph (Yang et al., 2018)), which is typically combined using connectivity (e.g. Jansen et al., 2017), embedding (e.g. Tu et al., 2020), or other features. Due to the difficulty of combining free text (Jansen, 2018), these methods typically reach peak performance when combining only a small number of facts together – typically two or three.

A middle-ground exists between these two extremes, where semi-structured knowledge bases of text (such as tables) are used to support multi-hop inference (e.g. Sun et al., 2016). This approach offers many practical benefits, such as ease of knowledge base creation (over logical decomposition methods), and providing structure to help infer when combining facts is appropriate (versus free text methods). In spite of these benefits, it is often still challenging to implement inference models that compose (or “hop” between) facts expressed in tables of language data in practice, and practitioners tend to resort to using complex models (such as integer linear programming (e.g. TableILP; Khashabi et al., 2016)) that significantly increase development time and limit interpretability, maintainability, and reuse.

This work presents an easy-to-use scripting language paired with an open source solver and interpreter designed to make compositional inference over semi-structured knowledge bases of tables easy, particularly when those tables express knowledge as lightly structured sentences. The contributions of this work are:

1. The CoSATA Solver, a stand-alone solver for Constraint Satisfaction over Tables of text. The CoSATA language allows easily expressing large multi-hop “inference patterns” that describe how facts typically connect across tables in a knowledge base to express a larger compositional solution. The optimized multi-threaded solver supports advanced features for dealing with text, including enumerative variable span detection, and robustness to surface form variations with patterns that can match words, lemmas, or parts-of-speech.

2. The CoSATA Interpreter, a hybrid imperative/declarative interpreted language for modeling simple inferences through minimally-specified simulations grounded in constraint patterns.

2 Language Description

The CoSATA language includes declarative features for performing constraint satisfaction over tables, and imperative features for expressing and executing models. The fundamental unit is the pattern, analogous to a class in object oriented programming, which (at a minimum) contains a declarative constraint pattern of table rows. The declarative features are sufficient for easily expressing variablized compositional patterns over collections of table rows, and the output of the stand-alone constraint satisfaction solver (e.g. solutions in JSON format) can serve as input to further processing.

The language also supports a suite of imperative features for expressing and executing models. In this paradigm, each pattern is considered a process that, if executed, imparts some change upon a small model of the world (such as an object warming from heat transfer) by executing a pattern code block. Agents, physical objects, and environments in the model are represented as objects, here sets of property-value pairs. A control script imports a library of patterns, initializes objects, and executes a small subset of patterns in a particular order to create a simulation. A state space keeps a log of each object, it’s properties, the patterns executed, and their resulting changes, to form a detailed and human-readable record of a simulation performed to arrive at a particular inference.

2.1 Declarative: Constraints over tables

Table Row Constraints: Each pattern contains one or more table row constraints, which collect interconnected sets of facts (table rows) from one or more tables based on satisfying constraints on the content of those facts. Each table row constraint requires: (a) a name for the row, (b) a table where rows are drawn from, and (c) a list of variablized constraint expressions that specific cells (columns) in a given row must satisfy in order for the entire constraint pattern to be valid. An example pattern with 8 table row constraints surrounding Changes of State of Matter is shown in Figure 2.

Constraint Expressions: Constraint expressions for table cells can be expressed as mixtures of
(a) An example listing for a constraint satisfaction pattern that collects 8 facts surrounding Changes of State of Matter.

(b) An example enumerated solution of the above constraint pattern.

(c) The variable values from this solution.

Figure 2: (Top) An example constraint satisfaction pattern expressed in the CoSATA. (Bottom) One of several solutions provided by the CoSATA solver when evaluating this pattern with a semi-structured knowledge base of tables.

strings (words, lemmas, or part-of-speech tags) and variables. Elements can be combined with simple boolean operations, as well as advanced booleans (e.g. optional elements, enumerative ANDs that automatically determine variable spans). Example constraint expressions are shown in Table 1.

Inheritance and Composite Patterns: Similar to object oriented programming, patterns can contain their own table row constraints, and/or inherit their table row constraints from one or more other patterns. This enables software engineering practices like problem decomposition into objects to be applied to constraint patterns. For example, the ChangeOfStateWithSubstanceFromTo pattern in Table 4 inherits table row constraints from three other patterns: one that describes the general concept of changes of state, another that describes the idea of a substance having a particular melting or boiling point, and a final pattern describing the substance being in it’s changed state. Because of this decomposition, these smaller generic patterns are available for reuse in other patterns.

2.2 Imperative: Executable Micro-Models

Objects: Objects are expressed as lists of property-value pairs that can be added, modified, or executed against. For example, an object named ice cube might have properties location:fridge and temperature:-4C.

Pattern Code Block: Each pattern can contain an imperative code block that, if executed, typically imparts changes to the objects or knowledge base suggestive of a particular process having taken place. For example, a heatTransfer pattern might have rows that match on any two objects that are touching, while its code block could decrease the temperature of the warmer object, and increase the temperature of the cooler object. Similarly, the code block in Figure 4 changes the state of matter of an object (for example from a solid to a liquid).
Example 1: Single variable assignment
Expression: ORGANISM: <organismName>
Cell Text: "large green plants"
Variables: <organismName> = "large green plants"

Example 2: Boolean AND with variables and strings
Expression: LOCATION: "in" + <northSouth> + " hemisphere"
Cell Text: "in the northern hemisphere"
Variables: <northSouth> = "northern"

Example 3: Matching part-of-speech tags
Expression: TIME: "smoothly" + "POS:CD"
Cell Text: "June 21st"
Variables: <month> = "June"

Example 4: Enumerative AND (multiple adjacent variables)
Expression: BY_THROUGH: <incDec> + <energy>
Cell Text: "increasing heat energy"
Variables: Two possible enumerations provided for constraint satisfaction:
<incDec> = "increasing", <energy> = "heat energy", or
<incDec> = "increasing heat", <energy> = "energy"

Example 5: Optional elements
Expression: DURATION: <dur1> + "to" + <dur2> + "hour"
Cell Text: "two to four hours"
Variables: Two possible enumerations provided for constraint satisfaction:
<dur1> = "two", <dur2> = "four", or
<dur1> = "two to four", <dur2> = <unpopulated opt>

Table 1: Example constraint expressions for a given table cell, evaluated against example cell text.

Requirements Specification: Code typically requires certain preconditions to be satisfied for execution to be valid, such as heatTransfer requiring two objects that have non-empty temperature properties. Patterns have specific functions for verifying that preconditions are met, as well as levels of preconditions (required, or recommended).

Model Control Script: Models take the form of small, easily-composed control scripts that import a library of patterns, initialize the objects required for a model, then sequentially execute a series of patterns that impart changes on those objects. For example, the control script in Figure 3 initializes three objects: an ice cube, freezer, and outside environment. The ice cube begins in the freezer, and is then moved to the outside environment. Heat transfer happens between the ice cube and outside environment until the ice cube meets the conditions for a Change of State. The Change of State then happens, in this case melting, changing the ice cube’s state of matter property from solid to liquid.

3 Solver and Interpreter

Both the constraint satisfaction solver and interpreter are implemented in Scala, with Stanford CoreNLP (Manning et al., 2014) used to provide tokenization, lemmatization, and part-of-speech tags for the knowledge base of tables. The solver pipeline first creates shortlists of rows that may potentially satisfy individual table row constraints for each pattern, then implements a backtrack search (e.g. Davis et al., 1962) to exhaustively find all combinations of table rows that meet the constraints for a given pattern (each unique collection of table rows that satisfies a given pattern is termed a solution of that pattern). While some powerful declarative features (such as enumerative ANDs with automatic variable span detection) are expensive to evaluate, nearly all stages of evaluation are multi-threaded for speed, and rely heavily on pre-computed look-up tables for evaluating constraint expressions. In practice, the patterns presented in Section 4 below are typically evaluated in between several seconds to a few minutes each.

Figure 3: An example micro-model control script (numbered states and instructions) with three objects (ice cube, outside environment, freezer), and the resulting state space changes (red highlights). This control script simulates the result of leaving an ice cube outside of a freezer. The full script and CoSATA interpreter output is provided in the distribution.

2Constraint satisfaction solvers are typically formulated to efficiently find a single solution that satisfies the constraints. In contrast, the solver presented in this work finds all possible solutions that can then be used for downstream processing.
The feasibility of generating constraint patterns (for downstream processing) or executable patterns (for modeling) is empirically demonstrated in the context of generating detailed multi-hop explanations to standardized elementary and middle school science exam questions drawn from the A12 Aristo Reasoning Challenge (Clark et al., 2018).

### 4 Example Solutions

Here the feasibility of generating constraint patterns (for downstream processing) or executable patterns (for modeling) is empirically demonstrated.

#### 4.1 Explanation Regeneration

The explanation regeneration task (Jansen and Ustalov, 2019) requires models to reconstruct large multi-fact gold explanations by selecting a set of interconnected facts from a knowledge base that match gold explanations provided in an explanation corpus. The task is very challenging, and current state-of-the-art models (e.g. Das et al., 2019) achieve nearly all of their performance by evaluating
Table 2: Ceiling performance of the converted explanatory patterns from the WorldTree V2 corpus evaluated using CoSATA on the explanation regeneration task.

| # Solutions Combined | Avg. Ceiling Accuracy | Avg. Extra Facts @ Ceiling |
|----------------------|-----------------------|---------------------------|
| Automatically Converted Patterns Only (N=353) | | |
| 1 | 56.0% | 7.8 |
| 2 | 67.5% | 11.2 |
| 3 | 70.8% | 12.6 |
| Automatic and Manually Curated Patterns (N=385) | | |
| 1 | 58.3% | 5.9 |
| 2 | 72.3% | 7.7 |
| 3 | 78.0% | 8.5 |

The Worldtree V2 corpus (Xie et al., 2020) includes detailed multi-fact explanations for 4,400 standardized science exam questions grounded in a knowledge base of 63 tables and approximately 10k table rows, as well as a set of 353 semi-automatically authored collections of facts surrounding specific subtopics, such as changes of state, inherited characteristics, or seasonal changes in daylight. Here, those 353 inference patterns were converted to the CoSATA constraint language using a prototype automatic converter, and all solutions to each pattern were enumerated with the CoSATA solver. 42 of the automatically converted patterns were selected based on frequency of use for manual curation, where they were further abstracted, decomposed, and debugged. Ceiling performance on the explanation regeneration task was calculated for a shortlist of ranked solutions, in terms of both single solutions, and combinations of up to three solutions, with results shown in Table 2. Performance is evaluated in terms of accuracy (proportion of gold rows included in the explanation) and the average number of “extra” facts included in the solutions but not included in the gold explanation. The results show that the pattern solutions enumerated by CoSATA have a ceiling performance of regenerating up to 58% of gold explanations when using a single solution, and up to 78% when combining up to three solutions. This empirically demonstrates the potential utility of using CoSATA patterns as input to downstream inference models that are able to accurately select which patterns to combine to generate an explanation. The inference patterns in this experiment and their solutions are included as examples in the distribution.

4.2 Micro-models and Interpreter

Constructing micro-models from scratch requires (i) authoring a knowledge base of semi-structured tables, (ii) authoring patterns that reference those tables (such as those in Figures 2 and 4), and (iii) constructing micro-model control scripts (such as the example in Figure 3) that describe, in a short series of steps, how processes interact with objects and agents to reach a given outcome.

To demonstrate this workflow, a series of 23 patterns including imperative code were authored for topics in heat transfer and changes of state, as well as a supporting semi-structured knowledge base containing several hundred facts across 21 tables including taxonomic relations, locations of common objects, processes causing discrete changes, and physical properties of substances. To support this effort, a prototype IDE called Procession (shown in Figure 5) was implemented using ELECTRON that integrates a table-editor (including D3-based visual taxonomy editor), MONACO-based code editor, and side-to-side debugger/editor for micro-model control scripts that enables fast debug cycles. These example imperative patterns and the resulting interpreter output of the control scripts are included as examples in the distribution.

5 Conclusion

CoSATA is an open-source constraint satisfaction solver for easily expressing and evaluating multi-fact compositional patterns in semi-structured tables of text, paired with an interpreted language that allows expressing micro-models. The tool, source, examples, and documentation are available at http://www.github.com/clulab/cosata/.
Acknowledgments

Thanks to Sebastian Thiem, who assisted in conducting the ceiling test of the WorldTree V2 patterns, and to Peter Clark for thoughtful discussions. The prototype IDE was developed in part under contract by Soft Design SRL. This work supported in part by the National Science Foundation (NSF Award #1815948, “Explainable Natural Language Inference”, to PJ).
