Abstract
This manuscript aims to analyze the effect of tin selenide (SnSe) on the sensing application of SPR biosensors. Tin selenide is the 2-dimensional transition metal dichalcogenide material. The proposed multilayer structure has a BK7 prism, a bimetallic layer of Au, tin selenide, and a graphene layer. Tin selenide is used to improve the performance parameters of the biosensor. The ε − SnSe nanosheet is placed in between two layers of gold (Au) in the Kretschmann configuration. The proposed configuration has a maximum sensitivity of 214 deg/RIU, 93.81% higher than the conventional sensor. The performance parameters like full width half maximum, detection accuracy, and quality factor have been analyzed. The ε − SnSe material is an air-stable 2-D. The proposed sensor is suitable for the analysis of chemical, medical, and biological analytes.

Keywords Surface plasmon resonance · Sensitivity · ε-Tin selenide nanosheets · Biosensor

Introduction
The tremendous development of surface plasmon resonance (SPR) technology has been reported for biomedical applications in the last few decades. The biosensor can detect cancer cells, DNA hybridization, antibody characterization, protein conformation, and the recent detection of the CORONA virus. In the biosensing field, to detect, analyze, and characterize the biomolecule, chemical, environment, and food [1–5], these biosensors are highly sensitive and facilitate real-time analysis of the contaminated analyte [6–8]. The SPR biosensor works on the phenomenon of attenuated total reflection (ATR). As the refractive index of the sensing layer varies [9, 10], a sharp dip in the resonance curve is obtained due to the adsorption of the incident light in the sensing medium [11, 12]. The Kretschmann configuration is the most acceptable configuration for designing the biosensor [13, 14]. This configuration has a prism, a thin layer of metal, and dielectric material. The layer of metal is used to generate the surface plasmons. The metal has poor adsorbability, so few layers of 2-dimensional material are associated with enhancing the biosensors’ performance [15–19]. When an incident light beam propagates through two media interfaces with the different refractive indexes at a particular angle and different dielectric constants, the surface plasmon gets excited [20]. These surface plasmons are electromagnetic waves traveling along the surface of the interface.

Single-layer SnSe also possesses fantastic electrical and optical properties and generates high interest as a 2D material beyond the predecessor members, displaying the same structure as graphene and phosphorene [21–23]. As a classical p-type IV-VI semiconductor, SnSe has a narrow gap (1.30 eV direct and 0.90 eV indirect), lower toxicity, and higher chemical stability [24]. That SnSe has a layered crystal structure similar to other IV-VII binary semiconductors, such as SnSe, GeS, and GeSe. In experiments, the assumption that unilaminar crystal SnSe would display different thermoelectric properties on different axes was authenticated by Zhao et al. [18], who manufactured hole-doped single-crystal SnSe [20]. A lot of SnSe allotropes have been investigated by density functional theory [18]. Monolayer
SnSe has outstanding thermoelectric properties and is also an eminent optoelectronic material. Still, there are few systematic studies on the optic and electric characteristics of SnSe allotropes. A metal-like Gold (Au) is not susceptible to oxidation and does not react with most chemicals, and hence it is often used as the metal film in sensors. At the metal–dielectric interface, the intensity of the incident light beam reaches a maximum and decays exponentially into media [25]. Since the metal and wave interaction is lossy, the EM field of a surface plasmon is concentrated in a vast majority in the dielectric medium close to the metal surface. The SPR phenomenon results in a graded reduction in the intensity of the reflected light. Surface plasmon resonance (SPR) sensors have generated considerable interest since they allow real-time detection of biomolecular interactions, rapid, level free, and valuable diagnostic tool for diseases having virus size of the order of nanometer or less [26].

In particular, graphene has attractive properties such as tunable electrical and optical characteristics [27], ring-type carbon structure and high surface-to-volume ratio. Thus, the adsorbates can easily interact with this structure, increasing the adsorption ability of the biosensors [28, 29].

Enhancing the sensor’s sensitivity is an emerging issue studied at different places; different methods and strategies have been proposed. The metals are used as plasmonics materials to generate the surface plasmons. Ag and Au are the most commonly used metals for the SPR sensor [30]. SPR technique help in estimating the dimension of DNA [31], RNA, or blood cells which cannot be measured directly due to its sizes being less than a nanometer. Therefore, the indirect measurement technique, which was evolved in 1968 by Kretschmann, opened a new avenue where the refractive index variation interacts with incident light photon and the reflected ray, thus quantifying the size or the nature of the virus under investigation. The binding of the legend differs; therefore, SPR has successfully detected the diverse effect and resulting refractive index change [32, 33].

The manuscript is sectioned as follows, the “Theoretical Model and Design Consideration” section proposed theoretical model and design consideration for the proposed biosensor. The “Results and Discussions” section consists of the results and discussion, and finally, the “Conclusions” section concludes the proposed work.

Theoretical Model and Design Consideration

We consider a modified biosensor configuration, as shown in Fig. 1. Each layer of the materials is assumed to be stacked along the z-axis. BK7 is chosen as a coupling prism in our structure, which is covered with one layer of gold-1, ε−SnSe layer is close to gold-1 layer, and the other side of ε−SnSe layer also connects with another gold-2 layer. Graphene layer is used as a biomolecular recognition element, which is close to the gold-2 layer. Besides, the thickness of the two layers of gold is not the same. We set the thickness of two layers of gold as \( W_1 = 40\, \text{nm} \) and \( W_3 = 20\, \text{nm} \), respectively. The thickness of \( \varepsilon−\text{SnSe} \) is \( W_2 = \text{SnSe} \times 1.5 \, \text{nm} \), where \( \text{SnSe} \) is the layer number of \( \varepsilon−\text{SnSe} \) sheets. Graphene is connected with the sensing layer for increasing the ability of macromolecular adsorption of the biosensor, and the thickness of graphene is \( W_4 = G \times 0.34\, \text{nm} \), where \( G \) is the layer number of graphene sheets. A TM-polarized light 633 nm is assumed to be an incident from one side of the prism and receives reflected light from the other. The received data can be used to calculate the reflectivity and sensitivity of the structure.

![Fig. 1 Heterostructure design of the proposed biosensor](image)
The refractive index \( n_{Prism} \) of BK7 layer is expressed as [34]

\[
n_{Prism} = \left( \frac{1.03961212 \lambda^2}{\lambda^2 - 0.00600069867} + \frac{0.231792344 \lambda^2}{\lambda^2 - 0.0200179144} + \frac{1.0104694 \lambda^2}{\lambda^2 - 103.560653} + 1 \right)^{\frac{1}{2}}
\]  

(1)

where \( \lambda \) is the wavelength of the applied optical signal.

The RI of the metal can be computed using the Drude model [35] by the formula:

\[
n_{1,3}(\lambda) = \sqrt{1 - \frac{\lambda^2}{\lambda^2_{p}(\lambda - \lambda_c)}}, \quad \text{where} \quad \lambda_p \text{ and } \lambda_c \text{ are the wavelengths of gold for plasma and collision and are taken as 1.6826 } \times 10^{-7} \text{m and 8.9342 } \times 10^{-5} \text{m, respectively [36].}
\]

The refractive index of \( \varepsilon - \text{SnSe} \) is considered as 4.4 + 3.53i [25] in the visible region. In the proposed multilayered structure, reflectivity is calculated by formula as follows:

\[
r_{pm1,pm2} = \frac{r_{pm1} + r_{m1,pm2} e^{2iK_{pm1,pm2}}}{1 + r_{pm1} r_{m1,pm2} e^{2iK_{pm1,pm2}}}
\]

where

\[
K_{ix} = \sqrt{\left(\frac{2\pi}{\lambda}\right)^2 \varepsilon_i - K_{ix}^2} = \text{prism}, \text{metal}_1, \text{dielectric}_1, \text{metal}_2, \text{dielectric}_2
\]

Results and Discussions

Emphasis has been made to improve the sensitivity and performance of biosensor low refractive index prism is used. BK7 prism is most suitable because it has a low refractive index. If the prism has a high refractive index, it provides a sharp dip in the resonance curve compared to the low RI prism. Low refractive prism provides better values of the FWHM, angle of resonance, the shift in the resonance curve, and sensitivity than the high refractive index’s prism. To get the high sensitivity and low FWHM, the flat end of the prism is polished with a 40-nm thick gold layer. A layer of the SnSe is deposited on the top of the Au layer. Another Au layer of 20 nm is deposited over the SnSe layer to enhance the sensor’s sensitivity. A single metal layer cannot increase

| Table 1 Optimized parameters for the proposed biosensor |
|--------------------------------------------------------|
| **Film of the materials** | **Used material** | **RI of the material at 633 nm** | **Thickness (nm)** |
|--------------------------|------------------|-------------------------------|-------------------|
| Layer I                  | Prism BK7        | 1.5151                        | -                 |
| Layer II                 | Au (Metal)       | 0.19572                       | 3.2561            | \( w_1 = 40 \) |
| Layer III                | \( \varepsilon - \text{tin selenide} \) | 4.4                            | 3.53              | \( w_2 = \text{SnSe } \times 1.5 \) |
| Layer IV                 | Au (metal)       | 0.18377                       | 3.4313            | \( w_3 = 20 \) |
| Layer V                  | Graphene         | 3                             | 1.1487            | \( w_4 = G \times 0.34 \) |
sensitivity too much, so a bimetallic layer is used. In the end, the graphene layer is spread over the gold-2 layer.

Figure 2 shows the reflectance plot of the biosensor. Figure 2a shows the design of a conventional sensor having two layers of Au and a sensing layer, i.e., SnSe = G = 0. A sharp dip in the resonance curve at a specific angle is obtained because SRs are excited. It clearly states that the absorption of the incident light occurs due to the SPs’ generation. The excursion at the dip is δθ = 0.97°, and sensitivity 194 deg/RIU is obtained. A single layer of the SnSe is considered, and the graphene layer is missing, i.e., SnSe = 1, G = 0, the sensitivity is enhanced due to the absorbance of the incident light. The change in the resonance angle δθ = 0.98° is obtained (shown in Fig. 2b), and sensitivity of 196 deg/RIU has been achieved. These values are better than the values obtained from the conventional biosensor. This improvement in the performance is attributed to the narrow bandgap of the SnSe material and better absorption efficiency.

A single graphene layer is present, and the SnSe layer is missing in the structure, i.e., SnSe = 0, G = 1. Now, the impact of the graphene is analyzed, and it is found that offset resonance dip and sensitivity both are improvised, and values of δθ = 0.99° and 198 deg/RIU are claimed respectively (shown in Fig. 2c). The enhanced sensitivity and the increase in resonance curve offset dip in this structure are attributed to the higher adsorption rates due to the large surface area and rich π conjugation structure offered by graphene, making it the appropriate choice for dielectric top layer SPR sensing applications [27, 38].

Another scenario was evaluated for the impact by introducing a single layer of SnSe and a monolayer of graphene in the biosensor (SnSe = 1, G = 1). This results in significant

---

**Fig. 2** Reflectance vs. incident angle (deg) at the same RI change with ε – SnSe and graphene (a) SnSe = 0, G = 0, (b) SnSe = 0, G = 1, (c) SnSe = 1, G = 0, (d) SnSe = 1, G = 1

© Springer
shifts and a dip in the resonance curve. The resonance angle was obtained as $\delta \theta = 1.02^\circ$, whereas the sensitivity was 214 deg/RIU as depicted in Fig. 2d. This comparative study reveals that the resonance angle offset increases with adding a single layer of graphene, a single layer of SnSe, compared to the conventional sensor. The best results were obtained by adding a single layer of graphene and a single layer of SnSe. Table 2 consists of performance parameters that are directly obtained from the theoretical study of the proposed work. Based on our knowledge, few parameters are better reported than the previously existing literature.

By comparing the relevant data, we can find that the resonance angle offset of the biosensor in our structure is larger than the traditional SPR structure due to the addition of graphene and the $\varepsilon - \text{SnSe}$ layer. The traditional SPR structure contains only a prism and gold layer. Hence, we can conclude that the sensitivity of biosensors in our structure has significantly improved compared with the traditional design by adding graphene and $\varepsilon - \text{SnSe}$ layer.

From the analyses made above, it is clear that the sensing layer’s refractive index can control the biosensor’s sensitivity. The enhancement of the sensitivity of the biosensor with graphene and $\varepsilon - \text{SnSe}$ layers is more than the single layer of these materials. The sensitivity of the sensor also depends on the RI of the sensing medium. Here, we select the sensing layer refractive index range from 1.368 to 1.373. It can be seen that as the refractive index of the sensing layer increases from 1.368 to 1.373, the sensitivity increases significantly (Fig. 3).

Figure 4a shows the impact of $\varepsilon - \text{SnSe}$ layers on the sensitivity of the biosensor. It is evident that with the introduction of several $\varepsilon - \text{SnSe}$ sheets, reflectance increases. Thus, the reflectance dip transfers to a larger incident angle and broadening of the SPR curve. Similarly, the effect of the change of the graphene layer on the sensitivity is given in Fig. 4b. A similarity in results with $\varepsilon - \text{SnSe}$ is observed. The reflectance dip transfers to a larger incident angle, and the broadening of the SPR curve takes place as the number of graphene layers is increased from 1 through 4. Thus, for analysis purposes, the values of $\text{SnSe} \text{and} G$ are confined to 0 and 1. For the values $\text{SnSe} \text{and} G = 2$ (and higher), it was observed that the shift in reflectance curve for various values of refractive indices of sensing layer is overlapping, or one of the reflectances was over 0.5 makes. It is challenging to measure accurate resonance angle in the dip for these values and lower sensitivity. Upon further analysis of the results as reported in Fig. 4a, b, it can be observed that the resonant angle offset is more affected by the increase in the number of SnSe sheets than the corresponding increase in the number of graphene layers.

Figure 5 shows the graphical representation of the performance parameters of the investigated sensor. Figure 5a shows the variation in FWHM and minimum reflectance to sensitivity. Figure 5b shows the detection accuracy and quality factor.

Table 3 comprises the performances of the biosensor for the maximum change in the RI is 0.005, the thickness of the Au layers is chosen 40 nm and 20 nm, the thickness of the $\varepsilon - \text{SnSe}$ is 1.5 nm, and thickness of the graphene 0.34. Table 4 reports the comparative analysis of the earlier published work. Table 4 reflects that all the referenced work is published, and it can consider that all are standard. The proposed work here shows the best performance parameters as well as high sensitivity.

Table 2 Final values of the different parameters for the sensor

| Structures (prism BK7) | Resonance angle ($\theta_{\text{SPR}}$) | $\delta \theta$ | FWHM | Sensitivity | Quality factor | DA | $K_{\min}$ |
|------------------------|----------------------------------------|----------------|-------|-------------|---------------|----|-----------|

Conclusions

The proposed biosensor is numerically simulated, and performance parameters are analyzed. The proposed sensor is a modified Kretschmann configuration-based SPR sensor with a bimetallic layer of gold, ε− SnSe, and graphene nanosheet-based modified. The study is carried out at 633 nm operating wavelength, and the highest sensitivity, 214 deg/RIU, is obtained for the monolayers of the ε− SnSe allotrope and graphene. The thickness of the gold layers is 40 and 20 nm, respectively, is taken in this work. The refractive index of the medium is taken as 1.368. The proposed sensor is useful for the study of the chemical, environment, biomolecule, and analytes.
