Abstract. We define root graded Lie superalgebras and study their connection with centerless cores of extended affine Lie superalgebras; our definition generalizes the known notions of root graded Lie superalgebras.

0. Introduction

Motivated by a construction appearing in the classification of finite dimensional simple Lie algebras containing nonzero toral subalgebras [22], S. Berman and R. Moody [10] introduced the notion of a Lie algebra graded by an irreducible reduced finite root system. This notion was generalized to Lie algebras graded by a locally finite root system and well studied through a variety of papers; recognition theorems for root graded Lie algebras are found in [10], [5], [21], [3], [6], [24] and their central extensions have been studied in [2], [3] and [25]. Roughly speaking, a root graded Lie algebra is a Lie algebra which is graded by the root lattice of an irreducible locally finite root system $R$ and contains a locally finite split simple Lie algebra whose root system is a full subsystem of $R$. One of the important phenomena in the study of root graded Lie algebras is their interaction with other classes of Lie algebras such as invariant affine reflection algebras [20] (see also [1], [4] and [18]); more precisely, the main ingredient in constructing an invariant affine reflection algebra is a root graded Lie algebra [20, §6].

There have been two different approaches to define root graded Lie superalgebras. One is working with Lie superalgebras which are graded by the root lattice of a locally finite root system and satisfy modified properties of a root graded Lie algebra [21]; the other one is working with a Lie superalgebra $\mathcal{L}$ containing a basic classical Lie superalgebra with a Cartan subalgebra $\mathcal{H}$ with respect to which $\mathcal{L}$ has a weight space decomposition satisfying certain properties [7]. In fact in the latter case, $\mathcal{L}$ is graded by the root lattice of the root system of a basic classical Lie superalgebra. Root systems of basic classical Lie superalgebras are exactly generalized root systems introduced by V. Serganova in 1996 [23]. Generalized root systems are called finite root supersystems in [26] where the author introduces locally finite root supersystems and gives their classification. Locally finite root supersystems which are extended by abelian groups appear as the root systems of specific Lie superalgebras named extended affine Lie superalgebras [27]. The so called core of an extended affine Lie superalgebra is a Lie superalgebra satisfying certain properties which are in fact a super version of the features defining a root graded Lie
algebra. This motivates us to define root graded Lie superalgebras in a general setting. Our definition is a generalization of both mentioned notions of root graded Lie superalgebras. In a series of papers, G. Benkart and A. Elduque studied Lie superalgebras graded by finite root supersystems $C(n), D(m, n), D(2, 1; α), F(4), G(3), A(m, n)$ and $B(m, n)$; see [7], [8] and [9]. We give a recognition theorem for Lie superalgebras graded by the locally finite root supersystem of type $BC(I, J)$.

This paper has been organized as follows. We begin the first section with gathering some information regarding the locally finite Lie superalgebra $\mathfrak{osp}(I, J)$ and conclude the section with a separate subsection devoted to extended affine Lie superalgebras and their root systems. The material of this section are used to prove our recognition theorem for $BC(I, J)$-graded Lie superalgebras. In Section 2, we define root graded Lie superalgebras and realize extended affine Lie superalgebras using root graded Lie superalgebras; we consider it as a first step of constructing extended affine Lie superalgebras. Last section is exclusively devoted to the study of $BC(I, J)$-graded Lie superalgebras.

1. Preliminaries

Throughout this work, $\mathbb{F}$ is a field of characteristic zero. Unless otherwise mentioned, all vector spaces are considered over $\mathbb{F}$. We denote the dual space of a vector space $V$ by $V^*$. If $V$ is a vector space graded by an abelian group, we denote the degree of a homogeneous element $x \in V$ by $|x|$; we also make a convention that if for an element $x$ of $V$, $|x|$ appears in an expression, by default, we assume that $x$ is homogeneous. For a superspace $V$, by $\text{End}_\mathbb{F}(V)$, we mean the superspace of linear endomorphisms of $V$. If $A$ is an abelian group, we denote the group of automorphisms of $A$ by $\text{Aut}(A)$ and for a subset $X$ of $A$, by $\langle X \rangle$, we mean the subgroup of $A$ generated by $X$. Also we denote the cardinal number of a set $S$ by $|S|$; and for two symbols $i, j$, by $δ_{i,j}$, we mean the Kronecker delta. We use $\cup$ to indicate the disjoint union and for a map $f : A \rightarrow B$ and $C \subseteq A$, by $f|_C$, we mean the restriction of $f$ to $C$. Finally, we denote the center of a Lie superalgebra $\mathcal{G}$ by $Z(\mathcal{G})$ and for $\mathcal{G}$-modules $V$ and $W$, by a $\mathcal{G}$-module homomorphism from $V$ to $W$, we mean a linear map $\varphi : V \rightarrow W$ satisfying

$$\varphi(xv) = x\varphi(v); \quad x \in \mathcal{G}, \quad v \in V.$$ 

1.1. On locally finite Lie superalgebra $\mathfrak{osp}(I, J)$. For two disjoint nonempty index sets $I, J$, suppose that $\{0, i, \bar{i} \mid i \in I \cup J\}$ is a superset with $|0| = |i| = |\bar{i}| = 0$ for $i \in I$ and $|j| = |\bar{j}| = 1$ for $j \in J$. Take $u$ to be a vector superspace with a basis $\{v_i \mid i \in I \cup \bar{I} \cup J \cup \bar{J} \cup \{0\}\}$ and

$$|v_i| := |i|; \quad i \in I \cup \bar{I} \cup J \cup \bar{J} \cup \{0\}$$

in which by $\bar{I}$ (resp. $\bar{J}$), we mean $\{\bar{i} \mid i \in I\}$ (resp. $\{\bar{j} \mid j \in J\}$). Take $(\cdot, \cdot)$ to be the skew supersymmetric bilinear form $(\cdot, \cdot)$ on $u$ defined by

$$(v_0, v_0) := 1, (v_i, v_j) := 0, (v_i, v_j) := 0, (v_i, v_j) = (-1)^{|i||j|} (v_j, v_i) := δ_{i,j}$$

for $i, j \in I \cup J$. Now for $j, k \in \{0\} \cup I \cup \bar{I} \cup J \cup \bar{J}$, define

$$(1.1) \quad e_{j,k} : u \rightarrow u; \quad v_i \mapsto δ_{k,i} v_j, \quad (i \in \{0\} \cup I \cup \bar{I} \cup J \cup \bar{J}).$$

Then

$$(1.2) \quad gl := \text{span}_{\mathbb{F}} \{e_{j,k} \mid j, k \in \{0\} \cup I \cup \bar{I} \cup J \cup \bar{J}\}$$
is a Lie superalgebra of Endₚ(υ). Suppose that γ ∈ {1, −1}. For i = 0, 1, take
\[(A_γ)_i := \{ s ∈ \mathfrak{g}t_i | str(s) = 0 \text{ and } (su, v) = γ(-1)^{|s||υ|}(u, sv), \forall u, v ∈ υ \}\]
and set
\[A_γ := (A_γ)_0 \oplus (A_γ)_1.\]
We next put
\[(1.4) g := A_{-1} \text{ and } s := A_1.\]
One knows that g is a Lie superalgebra of Endₚ(υ). Set
\[(1.5) h := \text{span}_F\{ h_t, d_k | t ∈ I, k ∈ J \}\]
in which for t ∈ I and k ∈ J,
\[h_t := e_{t, t} - e_{t, t} \text{ and } d_k := e_{k, k} - e_{k, k},\]
and for i ∈ I and j ∈ J, define
\[ε_i : h → F \quad \delta_j : h → F, \quad h_t → δ_i, t, \quad d_k → 0, \quad h_t → 0, \quad d_k → δ_j, k,\]
in which t ∈ I and k ∈ J. Then u is a g-module equipped with a weight space decomposition u = \(\oplus_{α ∈ Δ_u} u^α\) with respect to h, where
\[(1.6) Δ_u = \{0, \pm ε_i, \pm δ_j | i ∈ I, j ∈ J \}\]
with
\[u^0 = Fυ_0, \quad u^{ε_i} = Fυ_i, \quad u^{-ε_i} = Fυ_i, \quad u^{δ_j} = Fυ_j, \quad u^{-δ_j} = Fυ_j\]
for i ∈ I and j ∈ J. Also for γ ∈ {1, −1}, Aγ is a g-module having a weight space decomposition with respect to h. Taking R (resp. \(Δ_\gamma\)) to be the set of weights of \(A_{-1}\) (resp. \(A_1\)) with respect to h, we have
\[(1.7) R = \{±ε_r, ±(ε_r ± ε_s), ±δ_p, ±(δ_p ± δ_q), ±(ε_r ± δ_p) | r, s ∈ I, p, q ∈ J, r ≠ s\}, \]
\[Δ_\gamma = \{±ε_r, ±(ε_r ± ε_s), ±δ_p, ±(δ_p ± δ_q), ±(ε_r ± δ_p) | r, s ∈ I, p, q ∈ J, p ≠ q\}.\]
Moreover, for r, s ∈ I, p, q ∈ J, r ≠ s and p ≠ q, we have
\[(A_γ)^{ε_r} = \text{span}_F(ε_r, 0 + γe_{0, r}), \quad (A_γ)^{-ε_r} = \text{span}_F(ε_r, 0 + γe_{0, r}),\]
\[(A_γ)^{ε_r ± ε_s} = \text{span}_F(ε_r, s + γe_{s, r}), \quad (A_γ)^{-ε_r ± ε_s} = \text{span}_F(ε_r, s + γe_{s, r}),\]
\[(A_γ)^{-ε_r ± ε_s} = \text{span}_F(ε_r, s + γe_{s, r}), \quad (A_γ)^{-2ε_r} = \text{span}_F δ_{γ, 1} e_{s, r},\]
\[(A_γ)^{-2δ_p} = \text{span}_F δ_{γ, -1} e_{p, s}, \quad (A_γ)^{δ_p + δ_q} = \text{span}_F e_{p, q} - γe_{p, q},\]
\[(A_γ)^{-δ_p - δ_q} = \text{span}_F e_{p, q} - γe_{p, q}, \quad (A_γ)^{δ_p - δ_q} = \text{span}_F (e_{p, q} + γe_{q, p}),\]
\[(A_γ)^{δ_p} = \text{span}_F (e_{p, q} - γe_{p, q}), \quad (A_γ)^{-δ_p} = \text{span}_F (e_{p, q} + γe_{q, p}),\]
\[(A_γ)^{ε_r + δ_p} = \text{span}_F (e_{p, q} + γe_{p, q}), \quad (A_γ)^{-ε_r - δ_p} = \text{span}_F (e_{p, q} - γe_{p, q}),\]
\[(A_γ)^{ε_r - δ_p} = \text{span}_F (e_{p, q} - γe_{p, q}), \quad (A_γ)^{-ε_r + δ_p} = \text{span}_F (e_{p, q} + γe_{p, q}).\]
Proposition 1.8. Use the same notation as in the text and suppose that $I, J$ is a Lie subsuperalgebra of type $B_I(I, J)$ ($B(m, n)$ if $I = m, |J| = n$) and say $\mathfrak{h}$ is the standard splitting Cartan subalgebra of $\mathfrak{g}$. We also refer to the $\mathfrak{g}$-module $\mathfrak{s}$ as the natural module of $\mathfrak{g}$ and to the $\mathfrak{g}$-module $\mathfrak{s}$ as the second natural module of $\mathfrak{g}$. We take

$$\mathfrak{g}_B := \mathfrak{g} \cap \text{span}_\mathbb{F}\{\epsilon_{i,j} | i, j \in I \cup \bar{J} \cup \{0\}\} \quad \text{and} \quad \mathfrak{g}_C := \mathfrak{g} \cap \text{span}_\mathbb{F}\{\epsilon_{i,j} | i, j \in J \cup \bar{J}\}.$$  

Then $\mathfrak{g}_B$ (resp. $\mathfrak{g}_C$) is a locally finite split simple Lie algebra of type $B_I$ (resp. $C_J$) with splitting Cartan subalgebra $\text{span}_\mathbb{F}\{h_i | i \in I\}$ (resp. $\text{span}_\mathbb{F}\{d_j | j \in J\}$) and corresponding root system $\{0, \pm \epsilon_i, \pm (\epsilon_i \pm \epsilon_j) | i, j \in I, i \neq j\}$ (resp. $\{0, \pm 2\delta_p, \pm (\delta_p \pm \delta_q) | p, q \in J, p \neq q\}$) \cite{19}. Moreover,

$$\mathfrak{s}_B := \{x \in \mathfrak{s} \cap \text{span}_\mathbb{F}\{\epsilon_{i,j} | i, j \in I \cup \bar{J} \cup \{0\}\} | tr(x) = 0\}$$

is a $\mathfrak{g}_B$-module and

$$\mathfrak{s}_C := \{x \in \mathfrak{s} \cap \text{span}_\mathbb{F}\{\epsilon_{i,j} | i, j \in J \cup \bar{J}\} | tr(x) = 0\}$$

is a $\mathfrak{g}_C$-module. We finally note that if $|I| = m, |J| = n$ and $\mathcal{J} := \frac{1}{2m+1} \sum_{i \in \{0\} \cup I} \epsilon_{ii} + \frac{1}{2n} \sum_{i \in J \cup \bar{J}} \epsilon_{ii},$

then we have

$$\mathfrak{s}_0 = \mathfrak{s}_B \oplus \mathfrak{s}_C \oplus \mathcal{J}.$$

We have the following straightforward proposition.

**Proposition 1.8.** Use the same notation as in the text and suppose that $I', J' \subseteq I, J \subseteq J$. Consider \cite{17} and take

$$R' := R \cap \text{span}_\mathbb{F}\{\epsilon_i, \delta_p | i \in I', j \in J'\} \quad \text{and} \quad S := \Delta_s \cap \text{span}_\mathbb{F}\{\epsilon_i, \delta_p | i \in I', j \in J'\}.$$  

Then $G := \bigoplus_{\alpha \in R(\{0\})} \mathfrak{g}^\alpha \oplus \sum_{\alpha \in \Delta_s(\{0\})} [\mathfrak{g}^\alpha, \mathfrak{g}^{-\alpha}]$ and $S := \bigoplus_{\alpha \in \Delta_s(\{0\})} \mathfrak{s}^\alpha \oplus \sum_{\alpha \in \Delta_s(\{0\})} \mathfrak{g}^\alpha \cdot \mathfrak{s}^{-\alpha},$

then we have the following:

(i) $G$ is a Lie subsuperalgebra of $\mathfrak{g}$ isomorphic to $\mathfrak{osp}(I', J').$

(ii) Consider $\mathfrak{s}$ as a $G$-module, then $S$ is a $G$-submodule of $\mathfrak{s}$ isomorphic to the second natural module of $G.$

(iii) Suppose that $V$ is a $G$-module isomorphic to $\mathfrak{g}$ and set

$$W := \bigoplus_{\alpha \in R'(\{0\})} V^\alpha \oplus \sum_{\alpha \in R'(\{0\})} \mathfrak{g}^\alpha \cdot V^{-\alpha},$$

then $W$ is a $G$-module isomorphic to $G.$

(iv) If $K$ is a $g$-module isomorphic to $\mathfrak{s}$, then

$$T := \bigoplus_{\alpha \in S(\{0\})} K^\alpha \oplus \sum_{\alpha \in S(\{0\})} \mathfrak{g}^\alpha \cdot K^{-\alpha}$$

is a $G$-module isomorphic to the second natural module of $S.$

(v) Set $\Gamma_1 := \{0, \pm \epsilon_i, \pm \delta_j | i \in I', j \in J'\}.$ If $U$ is a $g$-module isomorphic to $\mathfrak{u},$

then

$$M := \bigoplus_{\alpha \in \Gamma_1(\{0\})} U^\alpha \oplus \sum_{\alpha \in \Gamma_1(\{0\})} \mathfrak{g}^\alpha \cdot U^{-\alpha}$$

is a $G$-module isomorphic to the natural module of $\mathfrak{osp}(I', J').$
1.2. The Lie superalgebra \( \mathfrak{osp}(m,n) \). In this subsection, we suppose the field \( F \) is algebraically closed and gather some facts regarding finite dimensional orthosymmetric Lie superalgebras. We keep the same notations as in the previous subsection and suppose \( I = \{1, \ldots, m\} \) and \( J = \{1, \ldots, n\} \). We denote the set of \( \mathfrak{g}_0 \)-module homomorphisms from a \( \mathfrak{g}_0 \)-module \( X \) to a \( \mathfrak{g}_0 \)-module \( Y \) by \( \text{hom}_{\mathfrak{g}_0}(X,Y) \).

**Proposition 1.9.** Suppose that \( \frac{2n}{2m+1} \not\in \mathbb{Z} \), then

\[
\begin{align*}
\text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{u}_0, \mathfrak{s}_0) &= \{0\}, & \text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{u}_1, \mathfrak{s}_0) &= \{0\}, \\
\text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{u}_0, \mathfrak{s}_1) &= \{0\}, & \text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{u}_1, \mathfrak{s}_1) &= \{0\}, \\
\text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{s}_0, \mathfrak{u}_0) &= \{0\}, & \text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{s}_1, \mathfrak{u}_0) &= \{0\}, \\
\text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{s}_0, \mathfrak{u}_1) &= \{0\}, & \text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{s}_1, \mathfrak{u}_1) &= \{0\}, \\
\text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{u}_0, \mathfrak{g}_0) &= \{0\}, & \text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{u}_1, \mathfrak{g}_0) &= \{0\}, \\
\text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{u}_0, \mathfrak{g}_1) &= \{0\}, & \text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{u}_1, \mathfrak{g}_1) &= \{0\}, \\
\text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{g}_0, \mathfrak{u}_0) &= \{0\}, & \text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{g}_1, \mathfrak{u}_0) &= \{0\}, \\
\text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{g}_0, \mathfrak{u}_1) &= \{0\}, & \text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{g}_1, \mathfrak{u}_1) &= \{0\}.
\end{align*}
\]

**Proof.** We first note that \( \mathfrak{g}_1 \) is a \( \mathfrak{g}_0 \)-module isomorphic to \( \mathfrak{u}_0 \otimes \mathfrak{u}_1 \) and fix the base

\[
\{\epsilon_1 - \epsilon_2, \ldots, \epsilon_{m-1} - \epsilon_m, \epsilon_m - \epsilon_1, \delta_1 - \delta_2, \ldots, \delta_{n-1} - \delta_n, 2\delta_m\}
\]

for the root system of \( \mathfrak{g}_0 \). With respect to this base, we denote the finite dimensional irreducible \( \mathfrak{g}_0 \)-module of highest weight \( \lambda \) by \( V(\lambda) \) and recall that

\[
(1.10)
\]

for two finite dimensional irreducible highest weight modules \( V(\lambda) \) and \( V(\mu) \), \( V(\lambda) \otimes V(\mu) \) is decomposed into finite dimensional irreducible highest weight modules of highest weights of the form \( \mu + \lambda' \) for some \( \lambda' \) in the set of weights of \( V(\lambda) \);

see [13 Exercise 24.12]. We also recall that if \( V \) is an irreducible \( \mathfrak{g}_\mu \)-module and \( W \) is an irreducible \( \mathfrak{g}_c \)-module, then \( V \otimes W \) is an irreducible \( \mathfrak{g}_0 \)-module.

\[
\text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{u}_0, \mathfrak{s}_0) = \{0\}.
\]

Suppose that \( \mathfrak{u}_0 \otimes \mathfrak{u}_0 = \bigoplus_{i=1}^r V_i \) is the decomposition of the \( \mathfrak{g}_0 \)-module \( \mathfrak{u}_0 \otimes \mathfrak{u}_0 \) into finite dimensional irreducible highest weight \( \mathfrak{g}_0 \)-modules. Now we have

\[
\text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{u}_0, \mathfrak{s}_0) \simeq \text{hom}_{\mathfrak{g}_0}((\mathfrak{u}_0 \otimes \mathfrak{u}_0) \otimes \mathfrak{u}_1, \mathfrak{s}_0) \simeq \bigoplus_{i=1}^r \text{hom}_{\mathfrak{g}_0}(V_i \otimes \mathfrak{u}_1, \mathfrak{s}_0) \simeq \bigoplus_{i=1}^r \text{hom}_{\mathfrak{g}_0}(V_i \otimes \mathfrak{u}_1, \mathfrak{s}_c) \simeq \bigoplus_{i=1}^r \text{hom}_{\mathfrak{g}_0}(V_i \otimes \mathfrak{u}_1, \mathfrak{s}_p) \simeq \bigoplus_{i=1}^r \text{hom}_{\mathfrak{g}_0}(V_i \otimes \mathfrak{u}_1, \mathfrak{F}\mathfrak{J}).
\]

If \( \text{hom}_{\mathfrak{g}_0}(V_i \otimes \mathfrak{u}_1, \mathfrak{s}_c) \neq \{0\} \) for some \( i \), then there is a nonzero \( \mathfrak{g}_0 \)-module homomorphism \( \varphi \in \text{hom}_{\mathfrak{g}_0}(V_i \otimes \mathfrak{u}_1, \mathfrak{s}_c) \neq \{0\} \). But \( V_i \otimes \mathfrak{u}_1 \) and \( \mathfrak{s}_c \) are irreducible, so \( \varphi \) is an isomorphism. We note that the set of weights of \( \mathfrak{s}_c \) as a \( \mathfrak{g}_0 \)-module is \( \{0, \pm(\delta_p \pm \delta_q) \mid 1 \leq p \neq q \leq n\} \) while the set of weights of \( V_i \otimes \mathfrak{u}_1 \) is a subset of \( \{\pm \epsilon_i \pm \delta_p, \pm \epsilon_i \pm \epsilon_j \pm \delta_p \mid 1 \leq i, j \leq m, 1 \leq p \leq n\} \) which is a contradiction. Using the same argument as above, we get that \( \text{hom}_{\mathfrak{g}_0}(V_i \otimes \mathfrak{u}_1, \mathfrak{s}_p) = \{0\} \) for all \( 1 \leq i \leq r \). Also as \( \dim(V_i \otimes \mathfrak{u}_1) > 1 \), there is no isomorphism from \( V_i \otimes \mathfrak{u}_1 \) to \( \mathfrak{F}\mathfrak{J} \) and so \( \text{hom}_{\mathfrak{g}_0}(V_i \otimes \mathfrak{u}_1, \mathfrak{F}\mathfrak{J}) = \{0\} \).
hom_{g_0}(g_1 \otimes u_1, s_0) = \{0\} : Consider the decomposition $u_1 \otimes u_1 = \oplus_{i=1}^t V_i$ of the $g_c$-module $u_1 \otimes u_1$ into irreducible submodules. We have

$$\text{hom}_{g_0}(g_1 \otimes u_1, s_0) \simeq \text{hom}_{g_0}(u_0 \otimes (u_1 \otimes u_1), s_0) \simeq \text{hom}_{g_0}(\oplus_{i=1}^s u_0 \otimes V_i, s_0) \simeq \oplus_{i=1}^s \text{hom}_{g_0}(u_0 \otimes V_i, s_0) \oplus \oplus_{i=1}^s \text{hom}_{g_0}(u_0 \otimes V_i, s_c) \oplus \oplus_{i=1}^s \text{hom}_{g_0}(u_0 \otimes V_i, F\mathcal{F}).$$

As before, since $\dim(u_0 \otimes V_i) > 1$, there is no $g_0$-module isomorphism from $u_0 \otimes V_i$ to $F\mathcal{F}$, so $\text{hom}_{g_0}(u_0 \otimes V_i, F\mathcal{F}) = \{0\}$. Also the set of weights of $u_0 \otimes V_i$ nontrivially intersects $\{\pm \delta_p, \pm \delta_q, \pm \epsilon_j \mid 1 \leq p, q \leq m, 1 \leq j \leq n\}$ while the set of weights of $g_0$-module $s_0$ and the set of weights of $g_0$-module $s_c$ are $\{\pm \epsilon_i, \pm \delta_j \mid 1 \leq i, j \leq m\}$ and $\{0, \pm \delta_p, \pm \delta_q \mid 1 \leq p < q \leq n\}$ respectively. Therefore $\text{hom}_{g_0}(u_0 \otimes V_i, s_0) = \{0\}$ and $\text{hom}_{g_0}(u_0 \otimes V_i, s_c) = \{0\}$, for all $1 \leq i \leq s$.

$$\text{hom}_{g_0}(g_1 \otimes s_0, u_0) = \{0\} : \text{Suppose that } u_0 \otimes s_0 = \oplus_{i=1}^t V(\eta_i) \text{ is the decomposition of the } g_0 \text{-module } u_0 \otimes s_0 \text{ into irreducible submodules and note that by (1.10), } \{\eta_i \mid 1 \leq i \leq t\} \subseteq \{\delta_1 \pm \delta_2 \mid 1 \leq p \leq n\}, \text{ so for } 1 \leq i \leq t, \eta_i \neq 0. \text{ Therefore, } \dim(V(\eta_i)) \neq 1 \text{ which in turn implies that } \dim(u_0 \otimes V(\eta_i)) \neq \dim(u_0). \text{ In particular, since } u_0 \otimes V(\eta_i) \text{ and } u_0 \text{ are irreducible } g_0 \text{-modules, we have}

(1.11) \quad \text{hom}_{g_0}(u_0 \otimes V(\eta_i), u_0) = \{0\}; 1 \leq i \leq t.$$

Next suppose that $u_0 \otimes s_B = \oplus_{i=1}^s \ominus V(\theta_i)$ is the decomposition of the $g_0$-module $u_0 \otimes s_B$ into finite dimensional irreducible highest weight submodules, then by (1.10), $\{\theta_i \mid 1 \leq i \leq s\} \subseteq \{2\epsilon_1, 2\epsilon_1 \pm \epsilon_j \mid 1 \leq j \leq m\}$. Therefore, for each $1 \leq i \leq s$, the set of weights of $V(\theta_i) \otimes u_1$ nontrivially intersects $\{2\epsilon_1 \pm \delta_p, 2\epsilon_1 \pm \epsilon_j \pm \delta_p \mid 1 \leq j \leq m, 1 \leq p \leq n\}$. So $V(\theta_i) \otimes u_1$ is not isomorphic to $u_0$ or $u_1$ as the set of weights of $u_0$ is $\{0, \pm \epsilon_j \mid 1 \leq j \leq m\}$ and the set of weights of $u_1$ is $\{\pm \delta_p \mid 1 \leq p \leq n\}$; in particular, since $V(\theta_i) \otimes u_1, u_0$ and $u_1$ are irreducible $g_0$-modules, we have

(1.12) \quad \text{hom}_{g_0}(V(\theta_i) \otimes u_1, u_0) = \{0\} \quad \text{and} \quad \text{hom}_{g_0}(V(\theta_i) \otimes u_1, u_1) = \{0\}.

We also note that $g_1$ and $u_0$ as well as $g_1$ and $u_1$ are non-isomorphic irreducible $g_0$-modules, so we get that

(1.13) \quad \text{hom}_{g_0}(g_1 \otimes F\mathcal{F}, u_0) = \{0\} \quad \text{and} \quad \text{hom}_{g_0}(g_1 \otimes F\mathcal{F}, u_1) = \{0\}.

Now using (1.11)–(1.13), we have

$$\text{hom}_{g_0}(g_1 \otimes s_0, u_0) \geq \text{hom}_{g_0}(g_1 \otimes s_B, u_0) \oplus \text{hom}_{g_0}(g_1 \otimes s_c, u_0) \oplus \text{hom}_{g_0}(g_1 \otimes F\mathcal{F}, u_0) \simeq \text{hom}_{g_0}(u_0 \otimes s_B) \otimes u_0 \otimes u_0) \oplus \text{hom}_{g_0}(u_0 \otimes (u_1 \otimes s_c), u_0) \simeq \text{hom}_{g_0}(\oplus_{i=1}^s \ominus V(\theta_i) \otimes u_1, u_0) \oplus \text{hom}_{g_0}(u_0 \otimes \oplus_{i=1}^t V(\eta_i), u_0) \simeq \oplus_{i=1}^t \text{hom}_{g_0}(V(\theta_i) \otimes u_1, u_0) \oplus \oplus_{i=1}^t \text{hom}_{g_0}(u_0 \otimes V(\eta_i), u_0) = \{0\}.$$

$$\text{hom}_{g_0}(g_1 \otimes s_0, u_1) = \{0\} : \text{For this, we first note that if } 0 \neq \varphi \in \text{hom}_{g_0}(u_0 \otimes V(\eta_i), u_1), \text{ then } \varphi \text{ is an isomorphism and so } \dim(V(\eta_i)) = 2n/(2m+1) \notin \mathbb{Z}, \text{ a}$$. 
This together with (1.12) and (1.13) implies that
\[ \text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{s}_0, \mathfrak{u}_1) \simeq \text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{s}_R, \mathfrak{u}_1) \oplus \text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes \mathfrak{s}_C, \mathfrak{u}_1) \oplus \text{hom}_{\mathfrak{g}_0}(\mathfrak{g}_1 \otimes F^3, \mathfrak{u}_1) \]
\[ \simeq \text{hom}_{\mathfrak{g}_0}((u_0 \otimes \mathfrak{s}_R) \otimes \mathfrak{u}_1, \mathfrak{u}_1) \oplus \text{hom}_{\mathfrak{g}_0}(u_0 \otimes (u_1 \otimes \mathfrak{s}_C), \mathfrak{u}_1) \]
\[ \simeq \text{hom}_{\mathfrak{g}_0}((u_0 \otimes \mathfrak{s}_R) \otimes \mathfrak{u}_1, \mathfrak{u}_1) \oplus \text{hom}_{\mathfrak{g}_0}((u_0 \otimes \mathfrak{s}_0) \otimes V(\theta_1), \mathfrak{u}_1) \]
\[ \simeq \oplus_{i=1}^s \text{hom}_{\mathfrak{g}_0}(V(\theta_i) \otimes \mathfrak{u}_1, \mathfrak{u}_1) \oplus \oplus_{i=1}^t \text{hom}_{\mathfrak{g}_0}(u_0 \otimes V(\eta_i), \mathfrak{u}_1) \]
\[ \simeq \oplus_{i=1}^t \text{hom}_{\mathfrak{g}_0}(u_0 \otimes V(\eta_i), \mathfrak{u}_1) = \{0\}. \]

These together with [9] §3 and the fact that \( \mathfrak{s}_1 \) is a \( \mathfrak{g}_0 \)-module isomorphic to the \( \mathfrak{g}_0 \)-module \( \mathfrak{g}_1 \), completes the proof. \( \square \)

Recall (1.7) and suppose that \( |I| = m, |J| = n \). One knows that
\[ \Pi := \{ \delta_1 - \delta_2, \delta_2 - \delta_3, \ldots, \delta_{n-1} - \delta_n, \delta_n - \epsilon_1, \epsilon_1 - \epsilon_2, \ldots, \epsilon_{m-1} - \epsilon_m, \epsilon_m \} \]
is a fundamental system for the root system \( R \) of the finite dimensional classical simple Lie superalgebra \( \mathfrak{g} \) with respect to the positive system
\[ \{ \delta_p + \delta_q, 2\delta_p, \delta_p, \epsilon_i, \epsilon_i \pm \epsilon_j, 1 \leq i < j \leq m, 1 \leq p < q \leq n \} \]
Set \( \rho := (1/2) \sum_{\alpha \in R^+_0} \alpha - (1/2) \sum_{\alpha \in R^+_1} \alpha \), where \( R^+_0 \) (resp. \( R^+_1 \)) is the set of positive even (resp. odd) roots, then we know from [11] (2.2) that
\[ \text{the Casimir element } \Gamma \text{ of } \mathfrak{g} \text{ acts on the highest weight } \mathfrak{g} \text{-module of highest weight } \lambda \text{ as } (\lambda, \lambda + 2\rho) \text{id} \]
where “id” indicates the identity map. Moreover, we have
\[ (\lambda, \lambda + 2\rho) = \begin{cases} -2(n - m) & \text{if } \lambda = \delta_1 \\ -2 - 4(n - m) & \text{if } \lambda = 2\delta_1 \\ 2 - 4(n - m) & \text{if } \lambda = \delta_1 + \delta_2. \end{cases} \]

Using [11] Thm. 2.14 (see also [15] Thm. 8), we get that the only nonzero elements of
\[ \Psi := R \cup \{ \pm 2\epsilon_i | 1 \leq i \leq m \} \]
which can be the highest weight for a finite dimensional irreducible \( \mathfrak{g} \)-module are
\[ 2\delta_1, \delta_1 + \delta_2, \delta_1 \text{ if } n \geq 2, \]
\[ 2\delta_1, \delta_1 + \epsilon_1, \delta_1 \text{ if } n = 1. \]

One knows that up to isomorphism, the only finite dimensional irreducible \( \mathfrak{g} \)-module whose highest weight is \( 2\delta_1 \) (resp. \( \delta_1 \)) is \( \mathfrak{g} \) (resp. \( \mathfrak{u} \)). Also up to isomorphism, \( \mathfrak{s} \) is the only finite dimensional irreducible \( \mathfrak{g} \)-module whose highest weight is \( \delta_1 + \delta_2 \) if \( n \neq 1 \) and \( \epsilon_1 + \delta_1 \) if \( n = 1 \). The following lemma and its corollary are a slight generalization of a result of [9] §3.

**Lemma 1.17.** Let \( n \neq 1 \) and consider (1.16). Suppose that \( X \) is a finite dimensional \( \mathfrak{g} \)-module equipped with a weight space decomposition with respect to \( \mathfrak{h} \) whose set of weights is contained in \( \Psi \). Suppose that \( Y \) is an irreducible \( \mathfrak{g} \)-submodule of \( X \) isomorphic to one of the \( \mathfrak{g} \)-modules \( \mathfrak{g}, \mathfrak{u}, \mathfrak{s} \) or the trivial module such that \( X/Y \) is also an irreducible \( \mathfrak{g} \)-module isomorphic to one of the above \( \mathfrak{g} \)-modules, then \( X \) is completely reducible.
Proof. For \( x \in X \), we denote the image of \( x \) in \( X/Y \) under the canonical epimorphism \( \pi : X \to X/Y \) by \( \bar{x} \). Since \( Y \) and \( X/Y \) are finite dimensional irreducible \( g \)-modules, they are highest weight modules. Suppose that \( \lambda \) and \( \mu \) are the highest weights of \( Y \) and \( X/Y \) respectively. We first suppose that \( (\lambda, \lambda + 2\rho) \neq (\mu, \mu + 2\rho) \). If \( r \) is an eigenvalue of the action of the Casimir element \( \Gamma \) on \( X \), then there is a nonzero \( x \in X \) with \( \Gamma x = rx \), so \( \Gamma \bar{x} = r\bar{x} \). This means that either \( \bar{x} = 0 \) or \( r = (\mu, \mu + 2\rho) \) by (1.14). In the former case, \( x \in Y \) and so \( r = (\lambda, \lambda + 2\rho) \). Therefore, the only eigenvalues for the action of \( \Gamma \) on \( X \) are \( (\lambda, \lambda + 2\rho) \) and \( (\mu, \mu + 2\rho) \); in particular \( X = X_{\lambda} \oplus X_{\mu} \) in which \( X_{\lambda} \) and \( X_{\mu} \) are the generalized eigenspaces corresponding to \( (\lambda, \lambda + 2\rho) \) and \( (\mu, \mu + 2\rho) \) respectively. Since \( \Gamma \) is a \( g \)-module homomorphism, \( X_{\lambda} \) and \( X_{\mu} \) are \( g \)-submodules of \( X \) with \( Y \subseteq X_{\lambda} \), therefore, we have \( X = \frac{X}{x} \oplus \frac{X-Y}{x} \). But the only eigenvalue for the action of \( \Gamma \) on \( X/Y \) is \( (\mu, \mu + 2\rho) \), so \( X_{\lambda}/Y = \{0\} \); i.e., \( X_{\lambda} = Y \) is an irreducible \( g \)-module. This also implies that \( X_{\mu} \cong X/Y \) is an irreducible \( g \)-module. Therefore, \( X = X_{\lambda} \oplus X_{\mu} \) is completely reducible. This completes the proof in this case. So from now till the end of the proof, we assume \( (\lambda, \lambda + 2\rho) = (\mu, \mu + 2\rho) \). By (1.15), one of the following cases can happen:

- \( Y \) is isomorphic to \( X/Y \),
- one of \( Y \) and \( X/Y \) is the trivial module and the other one is isomorphic to \( u \),
- one of \( Y \) and \( X/Y \) is isomorphic to \( g \) and the other one is isomorphic to \( u \),
- one of \( Y \) and \( X/Y \) is isomorphic to \( s \) and the other one is isomorphic to \( u \).

Using the same argument as in [9, §3] together with Proposition 1.9, we get that in the first case, \( X \) is completely reducible and that the last three cases result in a contradiction but for the convenience of readers, we carry out the proof for one case. Suppose that \( Y \) is isomorphic to \( s \) and \( X/Y \) is isomorphic to \( u \), then by (1.15), 
\[-2(n-m) = 2 - 4(n-m) \text{ and } \frac{2n}{2n+1} \notin \mathbb{Z} \]. Consider \( X \) as a \( g_0 \)-module, then \( X_0 \) as well as \( X_i \) are completely reducible \( g_0 \)-modules and so for \( i = 0, 1 \), there is a \( g_0 \)-submodule \( Z_0 \) of \( X_0 \) with \( X_0 = Y_0 \oplus Z_0 \). Set \( Z := Z_0 \oplus Z_1 \) which is a \( Z_2 \)-graded subspace of \( X \). Since \( g \)-module \( X/Y \) is isomorphic to \( u \), \( Z \) as a \( g \)-module is isomorphic to \( u \). So \( X = Y_0 \oplus Y_1 \oplus Z_0 \oplus Z_1 \) is a decomposition of \( X \) into \( g_0 \)-modules with either \( Z_0 \cong u_0 \) and \( Z_1 \cong u_1 \) or \( Z_0 \cong u_0 \) and \( Z_1 \cong u_1 \). Since by Proposition 1.9,
\[
\text{hom}_{g_0}(g_1 \otimes u_0, s_0) = \{0\}, \quad \text{hom}_{g_0}(g_1 \otimes u_1, s_0) = \{0\}, \\
\text{hom}_{g_0}(g_1 \otimes u_0, s_1) = \{0\}, \quad \text{hom}_{g_0}(g_1 \otimes u_1, s_1) = \{0\},
\]
it follows that for \( i = 0, 1 \), \( g_i Z_i \subseteq Z \), and so \( gZ \subseteq Z \). This together with the fact that \( Z \) is a \( Z_2 \)-graded subspace of \( X \) implies that \( Z \) is a \( g \)-submodule of \( X \). Also as \( g \)-module \( X/Y \) is isomorphic to \( u \), \( Z \) as a \( g \)-module is isomorphic to \( u \). Therefore, \( X \) is completely reducible. \( \square \)

Corollary 1.18. Suppose that \( X \) is a finite dimensional \( g \)-module equipped with a weight space decomposition with respect to \( h \). If the set of weights of \( X \) is a subset of \( \Psi \), then \( X \) is completely reducible such that its irreducible constituents are isomorphic to one of \( g \)-modules \( g, \ s, \ u \) or the trivial \( g \)-module.

Proof. One knows that \( X \) has a composition series, say \( \{0\} = X_0 \subseteq X_1 \subseteq X_2 \subseteq \cdots \subseteq X_t = X \). For each \( 1 \leq i \leq t \), \( X_i \) is an \( h \)-submodule of \( X \) and so it inherits the weight space decomposition of \( X \) with respect to \( h \). This implies that the set of weights of \( X_i \) is contained in \( \Psi \) and so the set of weights of the irreducible
1.3. Extended affine Lie superalgebras and their root systems. In this subsection, we recall the notions of extended affine Lie superalgebras and extended affine root supersystems from [27]. We prove Lemma 2.28 which is essential for the study of root graded Lie superalgebras. In the sequel, by a symmetric form on an additive abelian group $A$, we mean a map $(\cdot, \cdot) : A \times A \rightarrow F$ satisfying

- $(a, b) = (b, a)$ for all $a, b \in A$,
- $(a + b, c) = (a, c) + (b, c)$ and $(a, b + c) = (a, b) + (a, c)$ for all $a, b, c \in A$.

In this case, we set $A^0 := \{a \in A \mid (a, A) = \{0\}\}$ and call it the radical of the form $(\cdot, \cdot)$. The form is called nondegenerate if $A^0 = \{0\}$. We note that if the form is nondegenerate, $A$ is torsion free and we can identify $A$ as a subset of $\mathbb{Q} \otimes \mathbb{Z}$. In the following, if an abelian group $A$ is equipped with a nondegenerate symmetric form, we consider $A$ as a subset of $\mathbb{Q} \otimes \mathbb{Z}$.

We call a triple $(\mathcal{L}, \mathcal{H}, (\cdot, \cdot))$ a super-toral triple if

1. $\mathcal{L} = L_0 \oplus L_1$ is a nonzero Lie superalgebra, $\mathcal{H}$ is a nontrivial subalgebra of $L_0$ and $(\cdot, \cdot)$ is an invariant nondegenerate even supersymmetric bilinear form $(\cdot, \cdot)$ on $\mathcal{L}$,
2. $\mathcal{L}$ has a weight space decomposition $\mathcal{L} = \bigoplus_{\alpha \in \mathcal{H}^*} \mathcal{L}^\alpha$ with respect to $\mathcal{H}$ via the adjoint representation; we note that as $L_0$ as well as $L_1$ are $\mathcal{H}$-submodules of $\mathcal{L}$, we have $L_0 = \bigoplus_{\alpha \in \mathcal{H}^*} (L_\alpha)^0$ and $L_1 = \bigoplus_{\alpha \in \mathcal{H}^*} (L_\alpha)^1$ with $(L_\alpha)^i := L_i \cap \mathcal{L}^\alpha$, $i = 0, 1$,
3. the restriction of the form $(\cdot, \cdot)$ to $\mathcal{H} \times \mathcal{H}$ is nondegenerate.

We call $R := \{\alpha \in \mathcal{H}^* \mid \mathcal{L}^\alpha \neq \{0\}\}$, the root system of $\mathcal{L}$ (with respect to $\mathcal{H}$). Each element of $R$ is called a root. We refer to elements of $R_0 := \{\alpha \in \mathcal{H}^* \mid (L_\alpha)^0 \neq \{0\}\}$ (resp. $R_1 := \{\alpha \in \mathcal{H}^* \mid (L_\alpha)^1 \neq \{0\}\}$) as even roots (resp. odd roots). We note that $R = R_0 \cup R_1$. Suppose that $(\mathcal{L}, \mathcal{H}, (\cdot, \cdot))$ is a super-toral triple with corresponding root system $R$ and take $p : \mathcal{H} \rightarrow \mathcal{H}^*$ to be the function mapping $h \in \mathcal{H}$ to $(h, \cdot)$. Since the form is nondegenerate on $\mathcal{H}$, the map $p$ is one to one. So for each element $\alpha$ of the image $\mathcal{H}^p$ of $\mathcal{H}$ under the map $p$, there is a unique $t_\alpha \in \mathcal{H}$ representing $\alpha$ through the form $(\cdot, \cdot)$. Now we can transfer the form on $\mathcal{H}$ to a form on $\mathcal{H}^p$, denoted again by $(\cdot, \cdot)$, and defined by

$$
(\alpha, \beta) := (t_\alpha, t_\beta) \quad (\alpha, \beta \in \mathcal{H}^p).
$$

It is proved that if for $\alpha \in R_i \setminus \{0\}$ ($i \in \{0, 1\}$), there are $x_\alpha \in (L_\alpha)^0$ and $x_{-\alpha} \in (L_{-\alpha})^{-1}$ such that $0 \neq [x_\alpha, x_{-\alpha}] \in \mathcal{H}$, then $\alpha$ is an element of $\mathcal{H}^p$ [27, Lem. 2.4].

**Definition 1.20.** A super-toral triple $(\mathcal{L} = L_0 \oplus L_1, \mathcal{H}, (\cdot, \cdot))$ (or $\mathcal{L}$ if there is no confusion), with root system $R = R_0 \cup R_1$, is called an extended affine Lie superalgebra if

1. (1) for each $\alpha \in R_i \setminus \{0\}$ ($i \in \{0, 1\}$), there are $x_\alpha \in (L_\alpha)^0$ and $x_{-\alpha} \in (L_{-\alpha})^{-1}$ such that $0 \neq [x_\alpha, x_{-\alpha}] \in \mathcal{H}$,
2. (2) for each $\alpha \in R$ with $(\alpha, \alpha) \neq 0$ and $x \in L^\alpha$, $adx : \mathcal{L} \rightarrow \mathcal{L}$ is a locally nilpotent linear transformation.
Suppose that \((\mathcal{L}, \mathcal{H}, (\cdot, \cdot))\) is an extended affine Lie superalgebra with root system \(R\). It is proved that for \(\alpha \in R_i (i = 0, 1)\) with \((\alpha, \alpha) \neq 0\), there are \(e_\alpha \in (\mathcal{L}_i)^\alpha\), \(f_\alpha \in (\mathcal{L}_i)^{-\alpha}\) such that \((e_\alpha, f_\alpha, h_\alpha) := \frac{2e_\alpha}{(\alpha, \alpha)}\) is an \(\mathfrak{sl}_2\)-super-triple in the sense that
\[
[e_\alpha, f_\alpha] = h_\alpha, [h_\alpha, e_\alpha] = 2e_\alpha, [h_\alpha, f_\alpha] = -2f_\alpha.
\]
Moreover, the sub-superalgebra \(G(\alpha)\) of \(G\) generated by \(\{e_\alpha, f_\alpha, h_\alpha\}\) is either isomorphic to \(\mathfrak{sl}_2\) or to \(\mathfrak{so}(2, 1)\); see [27].

**Definition 1.21.** Suppose that \((\mathcal{L}, \mathcal{H}, (\cdot, \cdot))\) is an extended affine Lie superalgebra with root system \(R\). The sub-superalgebra of \(\mathcal{L}\) generated by \(\mathcal{L}^\alpha\) for \(\alpha \in \{\beta \in R \mid (\beta, R) \neq \{0\}\}\) is called the core of \(\mathcal{L}\).

**Example 1.22.** A basic classical finite dimensional simple Lie superalgebra \(\mathcal{L}\) is an extended affine Lie superalgebra with \(\mathcal{L} = \mathcal{L}_c\).

By [27, Pro. 3.3], the root system of an extended affine Lie superalgebra is an extended affine root supersystem in the following sense.

**Definition 1.23.** Suppose that \(A\) is a nontrivial additive abelian group, \(R\) is a subset of \(A\) and \((\cdot, \cdot) : A \times A \rightarrow \mathbb{F}\) is a symmetric form. Set
\[
R^0 := R \cap A^0, \\
R^\times := R \setminus R^0, \\
R^\times_{re} := \{\alpha \in R \mid (\alpha, \alpha) \neq 0\}, \\
R_{re} := R^\times_{re} \cup \{0\}, \\
R^\times_{im} := \{\alpha \in R \setminus R^0 \mid (\alpha, \alpha) = 0\}, \\
R_{im} := R^\times_{im} \cup \{0\}.
\]
We say \((A, (\cdot, \cdot), R)\) is an extended affine root supersystem if the following hold:

\((S1)\)  \(0 \in R\), and \(\text{span}_\mathbb{Z}(R) = A\),

\((S2)\)  \(R = -R\),

\((S3)\)  for \(\alpha \in R^\times_{re}\) and \(\beta \in R\), \(2(\alpha, \beta)/(\alpha, \alpha) \in \mathbb{Z}\),

\((\text{root string property})\) for \(\alpha \in R^\times_{re}\) and \(\beta \in R\), there are nonnegative integers

\((S4)\)  \(p, q\) with \(2(\beta, \alpha)/(\alpha, \alpha) = p - q\) such that

\[\{\beta + k\alpha \mid k \in \mathbb{Z}\} \cap R = \{\beta - p\alpha, \ldots, \beta + q\alpha\},\]

\((S5)\)  for \(\alpha \in R_{im}\) and \(\beta \in R\) with \((\alpha, \beta) \neq 0\), \(\{\beta - \alpha, \beta + \alpha\} \cap R \neq \emptyset\).

If there is no confusion, for the sake of simplicity, we say \(R\) is an extended affine root supersystem in \(A\). An extended affine root supersystem \(R\) is called irreducible if \(R^\times\) cannot be written as a disjoint union of two nonempty orthogonal subsets. An extended affine root supersystem \((A, (\cdot, \cdot), R)\) is called a locally finite root supersystem if the form \((\cdot, \cdot)\) is nondegenerate.

**Example 1.24.** Extended affine root systems \([1]\) and invariant affine reflection systems \([20]\) are examples of extended affine root supersystems. Also a generalized root system \([23]\) is a locally finite root supersystem.

**Definition 1.25.** Suppose that \((A, (\cdot, \cdot), R)\) is a locally finite root supersystem.

- A subset \(S\) of \(R\) is called a sub-supersystem if the restriction of the form to \(\langle S \rangle\) is nondegenerate, \(0 \in S\), for \(\alpha \in S \cap R^\times_{re}, \beta \in S\) and \(\gamma \in S \cap R_{im}, \) with \((\beta, \gamma) \neq 0\), \(r_\alpha(\beta) \in S\) and \(\{\gamma - \beta, \gamma + \beta\} \cap S \neq \emptyset\).
A sub-supersystem $S$ of $R$ is called full if $\text{span}_Q S = \mathbb{Q} \otimes \mathbb{Z} A$.

If $(A, (\cdot, \cdot), R)$ is irreducible, $R$ is said to be of real type if $\text{span}_Q R_{re} = \mathbb{Q} \otimes \mathbb{Z} A$; otherwise, we say it is of imaginary type.

If $\{R_i \mid i \in I\}$ is a class of sub-supersystems of $R$ which are mutually orthogonal with respect the form $(\cdot, \cdot)$ and $R \setminus \{0\} = \bigcup_{i \in I} (R_i \setminus \{0\})$, we say $R$ is the direct sum of $R_i$’s and write $R = \bigoplus_{i \in I} R_i$.

The locally finite root supersystem $(A, (\cdot, \cdot), R)$ is called a locally finite root system if $R_{im} = \{0\}$; see [16].

We have the following straightforward lemma; see [26, Lem. 3.20]:

**Lemma 1.26.** If $\{(X_i, (\cdot, \cdot)_i, S_i) \mid i \in I\}$ is a class of locally finite root supersystems, then for $X := \bigoplus_{i \in I} X_i$ and $(\cdot, \cdot) := \bigoplus_{i \in I} (\cdot, \cdot)_i$ $(X, (\cdot, \cdot), S := \bigcup_{i \in I} S_i)$ is a locally finite root supersystem. Also each locally finite root supersystem is a direct sum of irreducible sub-supersystems.

**Definition 1.27.** (i) Two irreducible extended affine root supersystems $(A, (\cdot, \cdot)_1, R)$ and $(B, (\cdot, \cdot)_2, S)$ are called isomorphic if there is a group isomorphism $\varphi : A \rightarrow B$ and a nonzero scalar $r \in \mathbb{F}$ such that $\varphi(R) = S$ and $(a_1, a_2) = r(\varphi(a_1), \varphi(a_2))$ for all $a_1, a_2 \in A$.

(ii) Suppose that $(A, (\cdot, \cdot), R)$ is an extended affine root supersystem. The subgroup $W$ of $\text{Aut}(A)$ generated by $r_\alpha$, $\alpha \in R^*_a$, is called the Weyl group of $R$; we note that for $\alpha \in R^*_a$ and $a \in A$, (S1) and (S3) imply that $2(a, \alpha)/(\alpha, \alpha) \in \mathbb{Z}$ and so $r_\alpha : A \rightarrow A$ mapping $a \rightarrow a - \frac{2(a, \alpha)}{\alpha, \alpha} \alpha$ is a group automorphism.

**Theorem 1.28.** (see [16] §4.14, §8 and [26] Lem. 3.21) Suppose that $T$ is a nonempty index set and $U := \bigoplus_{t \in T} \mathbb{Z} \epsilon_t$ is the free $\mathbb{Z}$-module over the set $T$. Define the symmetric form

$$(\cdot, \cdot) : U \times U \rightarrow \mathbb{F}; \quad (\epsilon_i, \epsilon_j) = \delta_{i,j}, \text{ for } i, j \in T$$

and set

$$
\begin{align*}
\hat{A}_T &:= \{\epsilon_i - \epsilon_j \mid i, j \in T\} \text{ if } |T| > 1, \\
D_T &:= \{\pm(\epsilon_i \pm \epsilon_j) \mid i, j \in T, i \neq j\} \text{ if } |T| > 2, \\
B_T &:= \{\pm \epsilon_i, \pm(\epsilon_i \pm \epsilon_j) \mid i, j \in T, i \neq j\}, \\
C_T &:= \{\pm 2 \epsilon_i, \pm(\epsilon_i \pm \epsilon_j) \mid i, j \in T, i \neq j\}, \\
BC_T &:= B_T \cup C_T.
\end{align*}
$$

(1.29)

These are irreducible locally finite root systems in their $\mathbb{Z}$-span’s. Moreover, each irreducible locally finite root system is either an irreducible finite root system or an infinite locally finite root system isomorphic to one of these locally finite root systems.

We refer to locally finite root systems listed in [1,2,9] as type $A, D, B, C$ and $BC$ respectively. We note that if $R$ is an irreducible locally finite root system as above, then $(\alpha, \alpha) \in \mathbb{N}$ for all $\alpha \in R$. This allows us to define

$$
\begin{align*}
R_{sh} &:= \{\alpha \in R^x \mid (\alpha, \alpha) \leq (\beta, \beta) \text{ for all } \beta \in R\}, \\
R_{ex} &:= R \cap 2R_{sh} \text{ and } R_{lg} := R^x \setminus (R_{sh} \cup R_{ex}) \\
R_{red} &:= \{0\} \cup R_{sh} \cup R_{lg}.
\end{align*}
$$

The elements of $R_{sh}$ (resp. $R_{lg}, R_{ex}$ and $R_{red}$) are called short roots (resp. long roots, extra-long roots and reduced roots) of $R$. We point out that following the usual notation in the literature, the locally finite root system of type $A$ is denoted
by $\hat{A}$ instead of $A$, as all locally finite root systems listed above are spanning sets for $F \otimes_{\mathbb{Z}} U$ other than the one of type $A$ which spans a subspace of codimension 1.

**Convention 1.30.** We make a convention that if a locally finite root system $R$ is the direct sum of subsystems $R_i$, where $i$ runs over a nonempty index set $I$, for $* \in \{sh, lg, ex, red\}$, by $R_*$, we mean $\cup_{i \in I}(R_i)_*$. 

**Theorem 1.31 (20 Thm. 4.28).** Suppose that $T, T'$ are index sets of cardinal numbers greater than 1 with $|T| \neq |T'|$ if $T, T'$ are both finite. Fix a symbol $\alpha^*$ and pick $t_0 \in T$ and $p_0 \in T'$. Consider the free $\mathbb{Z}$-module $X := \mathbb{Z}\alpha^* \oplus \oplus_{t \in T} \mathbb{Z}\epsilon_t \oplus \oplus_{p \in T'} \mathbb{Z}\delta_p$ and define the symmetric form 

$$(\cdot, \cdot) : X \times X \rightarrow F$$

by

$$(\alpha^*, \alpha^*) := 0, (\alpha^*, \epsilon_{t_0}) := 1, (\alpha^*, \delta_{p_0}) := 1$$
$$(\alpha^*, \epsilon_t) := 0, (\alpha^*, \delta_q) := 0$$
$$(\epsilon_t, \delta_q) := 0, (\epsilon_t, \epsilon_s) := \delta_{t,s}, (\delta_{p}, \delta_{q}) := -\delta_{p,q}$$

$t \in T \setminus \{t_0\}, q \in T' \setminus \{p_0\}$

Take $R$ to be $R_{re} \cup R_{im}^\times$ as in the following table:

| type    | $R_{re}$                                                                 | $R_{im}^\times$ |
|---------|--------------------------------------------------------------------------|-----------------|
| $A(0,T)$| $\{\epsilon_t - \epsilon_s | t, s \in T\}$                             | $\pm \mathbb{W} \alpha^*$ |
| $C(0,T)$| $\{\pm (\epsilon_t \pm \epsilon_s) | t, s \in T\}$                   | $\pm \mathbb{W} \alpha^*$ |
| $A(T, T')$| $\{\epsilon_t - \epsilon_s, \delta_{p} - \delta_{q} | t, s \in T, p, q \in T'\}$ | $\pm \mathbb{W} \alpha^*$ |

in which $\mathbb{W}$ is the subgroup of $\text{Aut}(X)$ generated by the reflections $r_{\alpha} (\alpha \in R_{re} \setminus \{0\})$ mapping $\beta \in X$ to $\beta - \frac{2(\beta, \alpha)}{(\alpha, \alpha)} \alpha$, then $(A := \langle R, (\cdot, \cdot) |_{A \times A}, R \rangle)$ is an irreducible locally finite root supersystem of imaginary type and conversely, each irreducible locally finite root supersystem of imaginary type is isomorphic to one and only one of these root supersystems.

**Theorem 1.32 (20 Thm. 4.37).** Suppose $(X_1, (\cdot, \cdot)_1, S_1), \ldots, (X_n, (\cdot, \cdot)_n, S_n)$ for some $n \in \{2, 3\}$, are irreducible locally finite root systems. Set $X := X_1 \oplus \cdots \oplus X_n$ and $(\cdot, \cdot) := (\cdot, \cdot)_1 \oplus \cdots \oplus (\cdot, \cdot)_n$ and consider the locally finite root system $(X, (\cdot, \cdot), S := \bigcup_{i=1}^n S_i)$. Take $\mathbb{W}$ to be the Weyl group of $S$. If $1 \leq i \leq n$ and $S_i$ is a finite root system of rank $\ell \geq 2$, we take $\{\omega_1^i, \ldots, \omega_1^i\} \subseteq \mathbb{Q} \otimes_{\mathbb{Z}} X_i$ to be a set of fundamental weights for $S_i$ and if $S_i$ is one of infinite locally finite root systems $B_T, C_T, D_T$ or $BC_T$ as in 1.34, by $\omega_1^i$, we mean $\epsilon_1$, where $1$ is a distinguished element of $T$. Also if $S_i$ is one of the finite root systems $\{0, \pm \alpha\}$ of type $A_1$ or $\{0, \pm \alpha, \pm 2\alpha\}$ of type $BC_1$, we set $\omega_1^i := \frac{1}{2}\alpha$. Consider $\delta^*$ and $\hat{R} := \hat{R}_{re} \cup \hat{R}_{im}^\times$ as
in the following table:

| i  | \( S_i \subseteq (1 ≤ i ≤ n) \) | \( R_{ij} \) | \( \delta^* \) | \( R_{ij}^\delta \) | type             |
|----|-----------------------------------|----------------|----------|----------------|------------------|
| 1  | \( S_1 = \mathbb{R}, \) \( S_2 = \mathbb{R} \) | \( \omega_1 + \omega_2 \) | \( \pm \mathbb{A}^2 \) | \( \mathbb{A}(1, T) \) |
| 2  | \( S_1 = \mathbb{R}, \) \( S_2 = \mathbb{R} \) | \( \omega_1 + \omega_2 \) | \( \pm \mathbb{A}^2 \) | \( \mathbb{B}(T, T') \) |
| 3  | \( S_1 = \mathbb{R}, \) \( S_2 = \mathbb{R} \) | \( \omega_1 + \omega_2 \) | \( \pm \mathbb{A}^2 \) | \( \mathbb{C}(T, T') \) |
| 4  | \( S_1 = \mathbb{R}, \) \( S_2 = \mathbb{R} \) | \( \omega_1 + \omega_2 \) | \( \pm \mathbb{A}^2 \) | \( \mathbb{D}(T, T') \) |

For \( 1 ≤ i ≤ n \), normalize the form \((\cdot, \cdot)_i\) on \( X_i \) such that \((\delta^* \cdot, \delta^* \cdot) = 0\) and that for type \( D(2, T), (\omega_1^T, \omega_2^T) = (\omega_1^T, \omega_2^T)\). Then \((\bar{R}, (\cdot, \cdot)_{\bar{R}})\) is an irreducible, locally finite root superystem of real type and conversely, if \((\bar{X}, (\cdot, \cdot)_{\bar{X}})\) is an irreducible, locally finite root superystem of real type, it is either an irreducible, locally finite root system or isomorphic to one and only one of the locally finite root superystems listed in the above table.

**Lemma 1.33.** Suppose that \((\mathcal{L}, \mathcal{H}, (\cdot, \cdot))\) is an extended affine Lie superalgebra with irreducible root system \( R \). Set \( \mathcal{V} := \text{span}_\mathbb{R} R \) and denote the induced form on \( \mathcal{V} \) again by \((\cdot, \cdot)_\mathcal{V}\); see (1.19). Take \( \mathcal{V}^0 \) to be the radical of the form. Suppose that \( \mathcal{V} \to \bar{\mathcal{V}} := \mathcal{V}/\mathcal{V}^0 \) is the canonical projection map and take \( \bar{R} \) to be the image of \( R \) under the projection map “\( \sim \)”. Denote by \((\cdot, \cdot)_\bar{R}\), the induced form on \( \bar{R} \), then we have the following:

(i) \( (\bar{A} := (\bar{R}, (\cdot, \cdot)_{\bar{X}}))_{\bar{X} \times \bar{A}}, \bar{R} \) is an irreducible, locally finite root superystem.

(ii) There is a triple \((\bar{V}, \bar{R}, \{S_\alpha\}_{\alpha \in \bar{R}})\) in which

- \( \bar{V} \) is a subspace of \( \mathcal{V} \) with \( \mathcal{V} = \bar{V} \oplus \mathcal{V}^0 \),
- \( \bar{R} \subseteq \bar{V} \) and \( \bar{R} \) is a locally finite root superystem (in its \( \mathbb{Z}\)-span) isomorphic to \( R \); in particular, \( \bar{R}_{\text{re}} \) is a locally finite root system,
- for each \( \alpha \in \bar{R} \), \( S_\alpha \) is a nonempty subset of \( \mathcal{V}^0 \) such that:
  - \( \bar{R} = \cup_{\alpha \in \bar{R}} (\bar{R}_{\text{re}}^\alpha + S_\alpha) \),
  - \( \bar{R}_{\text{re}} \) is of real type,
  - \( \bar{R}_{\text{im}} \neq \{0\} \) and \( \bar{R} \) is of type \( X \neq A(1, T) \), then for all \( \alpha, \beta \in (\bar{R}_{\text{re}}^\alpha + S_\alpha) \), also for all \( \alpha, \beta \in (\bar{R}_{\text{re}}^\beta + S_\beta) \), setting \( \bar{S} := \bar{S}_\alpha \), we get that \( F \) is a subgroup of \( \mathcal{V}^0 \) and
  \[
  \bar{S} - 2S \subseteq S, \quad S + F \subseteq S \quad \text{and} \quad 2S + F \subseteq F.
  \]

**Proof.** Using the same argument as in [26] Lem. 3.10, one can see that \( \bar{R}_{\text{re}} \) is locally finite in its \( \mathbb{F}\)-span in the sense that it intersects each finite dimensional subspace of \( \text{span}_\mathbb{R} \bar{R}_{\text{re}} \) in a finite set. So using Lemmas 3.10, 3.12 and 3.21 of [26], we get that \( \bar{R} \) is an irreducible, locally finite root superystem in its \( \mathbb{Z}\)-span. Also using [26] Lem. 3.5); we get that \( \bar{R}_{\text{re}} \) is a locally finite root system and the restriction of
the form $\langle \cdot, \cdot \rangle$ to $\tilde{V}_{rc} := \text{span}_R \bar{R}_{rc}$ is nondegenerate. Therefore we have

\begin{equation}
(1.34)
\end{equation}

the restriction of the form $\langle \cdot, \cdot \rangle$ to $\tilde{V}_Q := \text{span}_Q \bar{R}_{rc}$ is nondegenerate.

Since $\bar{R}_{rc}$ is a locally finite root system, by [17] Lem. 5.1, it contains a $Z$-linearly independent subset $T$ such that

\begin{equation}
(1.35)
\end{equation}

in which by $\mathcal{W}_T$, we mean the subgroup of the Weyl group of $\bar{R}_{rc}$ generated by $r_{\bar{a}}$ for all $\bar{a} \in T$. On the other hand, we know there is a subset $\Pi$ of $R$ such that $\Pi$ is a $Z$-basis for $\text{span}_Z \bar{R}$; see [27] Lem. 3.13. This allows us to define the linear isomorphism

\[ \varphi : \text{span}_Q \bar{R} \rightarrow Q \otimes_Z \text{span}_Z \bar{R} \]

mapping $\bar{a}$ to $1 \otimes \bar{a}$ for all $\bar{a} \in \Pi$. Now suppose that $\bar{R}$ is of real type, then

\[ \varphi(\text{span}_Q \bar{R}_{rc}) = \text{span}_Q (1 \otimes \bar{R}_{rc}) = Q \otimes \text{span}_Z \bar{R} = \varphi(\text{span}_Q \bar{R}) \]

which in turn implies that $\text{span}_Q \bar{R} = \text{span}_Q \bar{R}_{rc}$. Therefore, $\text{span}_Q \bar{R} = \text{span}_Q T$ and so $\text{span}_Q \bar{R} = \text{span}_Q T$. But $T$ is $Z$-linearly independent and so it is $Q$-linearly independent. We now prove that $T$ is $F$-linearly independent. Suppose that $\{\bar{\alpha}_1, \ldots, \bar{\alpha}_n\} \subseteq T$ and $\{r_1, \ldots, r_n\} \subseteq F$ with $\sum_{i=1}^{n} r_i \bar{\alpha}_i = 0$. Take $\{a_j \mid j \in J\}$ to be a basis for $Q$-vector space $F$. For each $1 \leq i \leq n$, suppose $\{r_i^j \mid j \in J\} \subseteq Q$ is such that $r_i = \sum_{j \in J} r_i^j a_j$. Then for each $\bar{a} \in T$, we have

\[ 0 = \sum_{i=1}^{n} r_i \frac{2(\bar{\alpha}_i, \bar{\alpha})}{(\bar{\alpha}, \bar{\alpha})} = \sum_{i=1}^{n} \sum_{j \in J} r_i^j \frac{2(\bar{\alpha}_i, \bar{\alpha})}{(\bar{\alpha}, \bar{\alpha})} = \sum_{j \in J} \sum_{i=1}^{n} r_i^j \frac{2(\bar{\alpha}_i, \bar{\alpha})}{(\bar{\alpha}, \bar{\alpha})} a_j. \]

Since $\frac{2(\bar{\alpha}_i, \bar{\alpha})}{(\bar{\alpha}, \bar{\alpha})} \in Z$, we get that for each $j \in J$ and $\bar{a} \in T$,

\[ \left( \sum_{i=1}^{n} r_i^j \bar{\alpha}_i, \bar{\alpha} \right) = \sum_{i=1}^{n} r_i^j \left( \bar{\alpha}_i, \bar{\alpha} \right) = 0. \]

So by (1.34), $\sum_{i=1}^{n} r_i^j \bar{\alpha}_i = 0$ for all $j \in J$. But $T$ is $Q$-linearly independent and so $r_i^j = 0$ for all $1 \leq i \leq n$ and $j \in J$. This means that

\begin{equation}
(1.36)
\end{equation}

$T$ is $F$-linearly independent.

Next suppose that $\bar{R}$ is of imaginary type and fix $\bar{\alpha}^* \in R_{im}^\infty$. Using a modified version of the above argument together with [26] Lem. 3.14] (see also [26] Lem. 3.21]), we get that

\begin{equation}
(1.37)
\end{equation}

$T \cup \{\bar{\alpha}^*\}$ is $F$-linearly independent.

For each element $\alpha \in T$, we fix a preimage $\hat{\alpha} \in R$ of $\alpha$ under $\bar{\cdot}$ and set

\[ K := \begin{cases} \{\hat{\alpha} \mid \alpha \in T\} & \text{if } \bar{R} \text{ is of real type,} \\ \{\hat{\alpha} \mid \alpha \in T \cup \{\bar{\alpha}^*\}\} & \text{if } \bar{R} \text{ is of imaginary type.} \end{cases} \]

We have using [26] Pro. 3.14] together with (1.35) that $\tilde{V} = \text{span}_Z \bar{K}$. Therefore setting $\mathcal{V} := \text{span}_Z K$ and using (1.36) and (1.37), we get that $\mathcal{V} = \mathcal{V} \oplus \mathcal{V}^0$. We set $\bar{R} := \{\bar{\alpha} \in \bar{V} \mid \sigma \in \mathcal{V}^0, \bar{\alpha} + \sigma \in R\}$, then $\bar{R}$ is a locally finite root supersystem in its $Z$-span isomorphic to $\bar{R}$. Also since $K \subseteq R \cap \bar{R}$, $-K \subseteq R \cap \bar{R}$. So the subgroup
\(W_K\) of the Weyl group of \(R\) generated by the reflections based on real roots of \(K\), we have

\[
W_K(\pm K) \subseteq R \cap \hat{R} \quad \text{and} \quad \pm W_K = \begin{cases} (R_{re})_{\text{red}}^\times & \text{if } \hat{R} \text{ is of real type}, \\ \hat{R}^\times & \text{if } \hat{R} \text{ is of imaginary type}. \end{cases}
\]

We finally set \(S_\alpha := \{\sigma \in V^0 \mid \hat{\alpha} + \sigma \in R\} \text{ for } \hat{\alpha} \in \hat{R}\). Then \(R = \cup_{\alpha \in \hat{R}} (\hat{\alpha} + S_\alpha)\) and

\[
0 \in S_\alpha \quad \text{for } \hat{\alpha} \in \begin{cases} (\hat{R}_{re})_{\text{red}} & \hat{R} \text{ is of real type}, \\ \hat{R} & \hat{R} \text{ is of imaginary type}. \end{cases}
\]

Other assertions in the statement follow from the same argument as in Claims 3,4 of the proof of Theorem 3.17 of \([27]\). \(\square\)

2. Root graded Lie superalgebras

**Definition 2.1.** For a locally finite root supersystem \(R\) of type \(X\). Set

\[
R_0 := \begin{cases} \{\alpha \in R_{re} \mid 2\alpha \notin R\} \cup \{0\} & \text{if } X \neq BC(T, T') \\ R_{re} \setminus (R_{re}')_{sh} & \text{if } X = BC(T, T') \text{ and } R_{re} = R_{re}' \oplus R_{re}^2. \end{cases}
\]

and

\[
R_1 := R \setminus R_0.
\]

We call elements of \(R_0\) (resp. \(R_1\)) even (resp. odd) roots.

We note that for a locally finite root supersystem \(R\), \(R_0\) is a locally finite root system.

**Definition 2.2.** Suppose that \((A, (\cdot, \cdot), R)\) is a locally finite root supersystem and \(\Lambda\) is an additive abelian group. A Lie superalgebra \(L = L_0 \oplus L_1\) is called an \((R, \Lambda)\)-graded Lie superalgebra if

- the Lie superalgebra \(L\) is equipped with a \(\langle R \rangle\)-grading \(L = \oplus_{\alpha \in \langle R \rangle} L^\alpha\), that is
  - \(L_0\) as well as \(L_1\) are \(\langle R \rangle\)-graded subspaces,
  - \([L^\alpha, L^\beta] \subseteq L^{\alpha+\beta}\) for all \(\alpha, \beta \in \langle R \rangle\),
- the support of \(L\) with respect to the \(\langle R \rangle\)-grading is a subset of \(R\),
- \(L^0 = \sum_{\alpha \in R \setminus \{0\}} [L^\alpha, L^{-\alpha}]\),
- the Lie superalgebra \(L\) is equipped with a \(\Lambda\)-grading \(L = \oplus_{\lambda \in \Lambda} L^\lambda\) which is compatible with the \(\langle R \rangle\)-grading on \(L\), that is
  - \(L_0\) as well as \(L_1\) are \(\Lambda\)-graded subspaces,
  - \(L^\lambda\) is a \(\Lambda\)-graded subspace for each \(\alpha \in R\),
  - \([L^\lambda, L^\mu] \subseteq L^{\lambda+\mu}\) for all \(\lambda, \mu \in \Lambda\),
- there is a full subsystem \(\Phi\) of \(R\) such that for \(0 \neq \alpha \in \Phi\), there are \(0 \neq e \in 0L \cap L^\alpha\) and \(0 \neq f \in 0L \cap L^{-\alpha}\) with \(k_\alpha := [e, f] \in L_0 \setminus \{0\}\) and for \(\beta \in R\) and \(x \in L^\beta\), \([k_\alpha, x] = (\beta, \alpha)x\) (we call \(k_\alpha \mid \alpha \in \Phi \setminus \{0\}\) a set of toral elements and refer to \(\Phi\) as a grading subsystem).

An \((R, \Lambda)\)-graded Lie superalgebra \(L\) is called fine if for \(i = 0, 1\), the support \(L_i\) with respect to the \(\langle R \rangle\)-grading is a subset of \(R_i\); also it is called predivision if for \(\alpha \in R \setminus \{0\}\) and \(\lambda \in \Lambda\) with \(\lambda L^\alpha := \lambda L \cap L^\alpha \neq \{0\}\), there are \(0 \neq e \in \lambda L^\alpha\) and \(0 \neq f \in -\lambda L^{-\alpha}\) such that \(k := [e, f] \in L_0 \setminus \{0\}\) and for \(\beta \in R\) and \(x \in L^\beta\), \([k, x] = (\beta, \alpha)x\). An \((R, \{0\})\)-graded Lie superalgebra is called an \(R\)-graded Lie superalgebra.
Lemma 2.3. Suppose that \((A, \cdot, \cdot), R)\) is a locally finite root supersystem and \(\Lambda\) an additive abelian group. If \(G = \oplus_{\alpha \in R} \oplus_{\sigma \in \Lambda} G^{\alpha}\) is an \((R, \Lambda)\)-graded Lie superalgebra with a grading subsystem \(\Phi\), then so is \(G/Z(G)\). Moreover, if \(G\) is predivision, then \(G/Z(G)\) is also predivision.

Proof. Since \(Z(G)\) inherits the gradings on \(G\), for \(\alpha \in R\) and \(\sigma \in \Lambda\), we have
\[
\frac{\sigma G + Z(G)}{Z(G)} \cap \frac{G^\alpha + Z(G)}{Z(G)} = \frac{\sigma G^\alpha}{Z(G)}
\]
and that
\[
\frac{G}{Z(G)} = \frac{G_0 + Z(G)}{Z(G)} \oplus \frac{G_1 + Z(G)}{Z(G)} = \bigoplus_{\alpha \in R, \sigma \in \Lambda} \frac{\sigma G^\alpha + Z(G)}{Z(G)}.
\]
More precisely, \(G/Z(G)\) is equipped with compatible \((R)\) and \(\Lambda\)-gradings. Now we prove that \(Z(G) \subseteq G^0\). For this, we suppose \(\alpha \in R \setminus \{0\}\) and show that \(G^\alpha \cap Z(G) = \{0\}\). If \(G^\alpha = \{0\}\), there is nothing to prove, so suppose \(G^\alpha \neq \{0\}\). Since \(\text{span}_R \Phi = Q \otimes Z\), for each \(\beta \in R\), there is a nonzero integer \(n\) with \(n\beta \in \text{span}_Q \Phi\). This together with the fact that the form \((\cdot, \cdot)\) is nondegenerate on \(A = \text{span}_Z R\), guarantees the existence of an element \(\gamma \in \Phi\) with \((\alpha, \gamma) \neq 0\). Suppose that \(k_\gamma\) is a toral element of \(G\) corresponding to \(\gamma\). For each \(0 \neq x \in G^\alpha\), we have \([k_\gamma, x] = (\alpha, \gamma)x \neq 0\), so \(x \notin Z(G)\). This shows that \(G^\alpha \cap Z(G) = \{0\}\). To complete the proof, it is enough to show if \(e \in \lambda G^\alpha\) and \(f \in \lambda^{-1} G^{-\alpha}\) for some \(\alpha \in R \setminus \{0\}\) and \(\lambda \in \Lambda\) with \(k := [e, f] \in G_0 \setminus \{0\}\) such that \([k, x] = (\beta, \alpha)x\) for \(\beta \in R, x \in G^\beta\), then \(k \notin Z(G)\). So consider \(\alpha, \lambda, e, f\) and \(k\) as above. Since \(\alpha \neq 0\), as before, there is \(\beta \in \Phi\) with \((\alpha, \beta) \neq 0\). Now for \(0 \neq y \in 0 G^\beta\), we have \([k, y] = (\beta, \alpha)y \neq 0\). This shows that \(k \notin Z(G)\) and so we are done. \(\Box\)

Lemma 2.4. Suppose that \((\mathcal{L}, \mathcal{H}, (\cdot, \cdot))\) is an extended affine Lie superalgebra with irreducible root system \(R\). Keep the same notations as in Lemma 2.3 and set \(\Lambda := \langle \cup_{\alpha \in R} S_a \rangle\), then the core \(L_c\) of \(\mathcal{L}\) is a predivision \((\check{R}, \Lambda)\)-graded Lie superalgebra. Moreover, if \(R^0 \subseteq R_0\), then for \(i = 0, 1\), the support \((L_c)_i\) with respect to the \(\langle R^i \rangle\)-grading is \(R_i\).

Proof. We note that for each root \(\alpha \in R\), \(L^\alpha\) is a \(Z_2\)-graded subspace, so \(L_c\) is a \(Z_2\)-graded subsalgebra of \(L\). Moreover, we have
\[
L_c = \sum_{\check{\alpha} \in \check{R}, \sigma \in S_a} L^{\check{\alpha}+\sigma} + \sum_{\check{\alpha} \in \check{R}, \sigma \in S_{x}, \tau \in S_{-\sigma}} [L^{\check{\alpha}+\sigma}, L^{-\check{\alpha}+\tau}].
\]
Therefore, we have
\[
L_c = \sum_{\check{\alpha} \in \check{R}} (L_c)^{\check{\alpha}} = (L_c)_0 \oplus (L_c)_1 = \sum_{\sigma \in \Lambda} \lambda(L_c)
\]
where
\[
(L_c)^{\check{\alpha}} = \sum_{\sigma \in S_a} L^{\check{\alpha}+\sigma} \quad (\check{\alpha} \in \check{R}),
(L_c)_0 = \sum_{\check{\alpha} \in \check{R}} \sum_{\sigma \in S_a} \sum_{\tau \in S_{-\sigma}} [L^{\check{\alpha}+\sigma}, L^{-\check{\alpha}+\tau}],
(L_c)_0 = L_0 \cap L_c \quad \text{and} \quad (L_c)_1 = L_1 \cap L_c,
\]
\[
\lambda(L_c) = \sum_{\check{\alpha} \in \check{R}} L^{\check{\alpha}+\sigma} + \sum_{\check{\alpha} \in \check{R}} \sum_{\sigma \in S_a} [L^{\check{\alpha}+\sigma}, L^{-\check{\alpha}+\lambda-\sigma}] \quad (\lambda \in \Lambda).
\]
These define compatible \(\langle \check{R} \rangle\) and \(\Lambda\)-gradings on \(L_c\). Now set
\[
\check{\Phi} := \begin{cases} (\check{R}_{\text{re}})_{\text{red}} & \text{if } \check{R} \text{ is of real type} \\ \check{R} & \text{if } \check{R} \text{ is of imaginary type.} \end{cases}
\]
We know from Lemma 1.33 that $\dot{\Phi} \subseteq R$. Now for $\dot{\alpha} \in \dot{\Phi} \setminus \{0\}$, since $\mathcal{L}$ is an extended affine Lie superalgebra, by [27, Lem. 2.4], there are $e \in \mathcal{L}^\dot{\alpha} = 0(\mathcal{L}_c)^{-\dot{\alpha}}$ and $f \in \mathcal{L}^{-\dot{\alpha}} = 0(\mathcal{L}_c)^{-\dot{\alpha}}$ such that $[e, f] = t_{\dot{\alpha}}$ (we recall $t_{\dot{\alpha}}$ from Subsection 1.3).

Therefore, for $x \in \lambda(\mathcal{L}_c)^{\beta} \subseteq \mathcal{L}\beta + \lambda$ ($\beta \in \dot{R}$, $\lambda \in \Lambda$), we have

$$[t_{\dot{\alpha}}, x] = (\dot{\beta} + \lambda)(t_{\dot{\alpha}})x = (t_{\dot{\beta} + \lambda}, t_{\dot{\alpha}})x = (\dot{\beta} + \lambda, \dot{\alpha})x.$$  

Now assume $R^0 \subseteq R_0$, then using the same argument as in [27, Pro. 2.14], one gets that

\begin{equation}
(\ref{eq:2.5})
\end{equation}

- if $\dot{\alpha} \in \dot{R}_{rc}$ and $2\dot{\alpha} \notin \dot{R}$, then $\dot{\alpha} + S_{\dot{\alpha}} \subseteq R_0$,
- if $\dot{\alpha} \in \dot{R}_{rc}^\perp$ and $2\dot{\alpha} \in \dot{R}$, then $2\dot{\alpha} + S_{2\dot{\alpha}} \subseteq R_0$,
- if $\dot{\alpha} \in \dot{R}_{lm}$, then $\dot{\alpha} + S_{\dot{\alpha}} \subseteq R_1$,
- if $\dot{\alpha} \in \dot{R}_{rc}^\perp$ and $\dot{\alpha} + \sigma \in R_0$ for some $\sigma \in S_{\dot{\alpha}}$, then $\dot{\alpha} + \tau \notin R_1$ for all $\tau \in S_{\dot{\alpha}}$.

Now the result easily follows if $\dot{R}$ is not of type $BC(T, T')$, $B(T, T')$, $B(1, T)$, $B(T, 1)$ and $G(1, 2)$. So we just consider these mentioned types. From the classification table of Theorem 1.32, we know that for types $BC(T, T')$, $B(T, T')$, $B(1, T)$, $B(T, 1)$ and $G(1, 2)$, $\dot{R}_{rc}$ has two irreducible components $\dot{R}_{rc}^\perp$ and $\dot{R}_{rc}$ and that $\dot{R}_{lm} = (\dot{R}_{rc})_{sh} + (\dot{R}_{rc})_{sh}$. We also recall from Lemma 1.33 that $S = S_{\dot{\alpha}}$, for all $\dot{\alpha} \in (\dot{R}_{rc})_{sh}$, and $F = S_{\beta}$, for all $\beta \in \dot{R}_{lm} \cup \dot{R}_{lm}$, satisfy $S + F = S$. Considering (2.5), to complete the proof, we just need to show that if $\{i, j\} = \{1, 2\}$, $\{r, s\} = \{0, 1\}$ and $\dot{\alpha} + \sigma \in R_r$ for some $\dot{\alpha} \in (\dot{R}_{rc})_{sh}$ and $\sigma \in S$, then

$$(\dot{R}_{rc})_{sh} + S \subseteq \dot{R}_r \quad \text{and} \quad (\dot{R}_{rc})_{sh} + S \subseteq \dot{R}_s.$$  

So suppose that $\dot{\alpha} + \sigma \in R_r$ for some $\dot{\alpha} \in (\dot{R}_{rc})_{sh}$ and $\sigma \in S$. By (2.5), $\dot{\alpha} + \tau \in R_r$ for all $\tau \in S$. Fix $\beta \in (\dot{R}_{rc})_{sh}$ and $\tau \in S$. Set $\alpha := \dot{\alpha} + \tau \in R_r$ and pick $e_{\alpha} \in \mathcal{L}_\alpha$ and $e_{-\alpha} \in \mathcal{L}_{-\alpha}$ such that $[e_{\alpha}, e_{-\alpha}] = t_{\alpha}$. We know that for each $\zeta \in F$, $\gamma := \dot{\beta} - \dot{\alpha} + \zeta \in R_1$ and that $[e_{-\alpha}, \mathcal{L}_{\gamma}] \subseteq \mathcal{L}_{-\alpha + 2\beta - \alpha - \zeta} = \{0\}$, so we get

$$\{0\} \neq \langle \gamma, \alpha \rangle \mathcal{L}_{\gamma} = [t_{\alpha}, \mathcal{L}_{\gamma}]$$

$$= [(e_{\alpha}, e_{-\alpha}), \mathcal{L}_{\gamma}]$$

$$= [e_{\alpha}, [e_{-\alpha}, \mathcal{L}_{\gamma}]] - (-1)^r[e_{-\alpha}, [e_{\alpha}, \mathcal{L}_{\gamma}]]$$

$$= -(-1)^r[e_{-\alpha}, [e_{\alpha}, \mathcal{L}_{\gamma}]]$$

which implies that $\{0\} \neq [e_{\alpha}, \mathcal{L}_{\gamma}] \subseteq \mathcal{L}_{-\alpha + 2\beta - \alpha - \zeta}$. Therefore,

$$\dot{\beta} + \tau + \zeta \in R_s \quad (\tau \in S, \zeta \in F).$$  

But $S + F = S$, so we have $\dot{\beta} + \eta \in R_s$ for $\eta \in S$. This means that

$$(\dot{R}_{rc})_{sh} + S \subseteq R_s.$$  

Finally using the same argument as above, we get that $(\dot{R}_{rc})_{sh} + S \subseteq R_r$. This completes the proof. 

\begin{lemma}
Suppose that $(\dot{\Lambda}, (\cdot, \cdot), \dot{R})$ is a locally finite root supersystem, $\Lambda$ a torsion free additive abelian group and $\mathcal{G} = \mathcal{G}_0 \oplus \mathcal{G}_1 = \bigoplus_{\lambda \in \Lambda} \oplus_{\dot{\alpha} \in \dot{R}} \lambda \mathcal{G}^\dot{\alpha}$ an $(\dot{R}, \Lambda)$-graded Lie superalgebra with a grading subsystem $\dot{\Phi}$ and a set $\{k_\dot{\alpha} \mid \dot{\alpha} \in \dot{\Phi} \setminus \{0\}\}$ of toral elements. For $\dot{\alpha} \in \dot{\Phi} \setminus \{0\}$, fix $e_{\dot{\alpha}} \in 0\mathcal{G}^{\dot{\alpha}}$ and $f_{\dot{\alpha}} \in 0\mathcal{G}^{-\dot{\alpha}}$ such that $k_\dot{\alpha} = [e_{\dot{\alpha}}, f_{\dot{\alpha}}]$ and take $T$ to be the linear span of $\{k_\dot{\alpha} \mid \dot{\alpha} \in \dot{\Phi} \setminus \{0\}\}$. Suppose that $\mathcal{G}$ is equipped with an even nondegenerate invariant supersymmetric bilinear form $(\cdot, \cdot)$.
\end{lemma}
(i) Suppose that \( \hat{R} = \oplus_{j \in I} \hat{R}^{(j)} \) is the decomposition of \( \hat{R} \) into irreducible sub-supersystems. Suppose that \( \{ \hat{\alpha}_i \mid i \in I \} \subseteq \hat{\Phi} \) is such that \( \{ \hat{k}_{\hat{\alpha}_i} \mid i \in I \} \) is a basis for \( T \). If \( j \in J \) and \( \hat{\gamma} \in \hat{\Phi}^{(j)} := \hat{R}^{(j)} \cap \hat{\Phi} \), then \( \hat{k}_{\hat{\gamma}} \in \text{span}_\mathbb{F} \{ \hat{k}_{\hat{\alpha}_i} \mid i \in I, \hat{\alpha}_i \in \hat{\Phi}^{(j)} \} \). Moreover, if \( \{ \hat{r}_i \mid i \in I \} \subseteq \mathbb{F} \) with \( \hat{k}_{\hat{\gamma}} = \sum_{i \in I} \hat{r}_i \hat{k}_{\hat{\alpha}_i} \), we have \( \hat{\gamma} = \sum_{i \in I} \hat{r}_i \hat{\alpha}_i \in \mathbb{F} \otimes_\mathbb{Z} \hat{A} \) (here we identify \( \hat{A} \) as a subset of \( \mathbb{F} \otimes_\mathbb{Z} \hat{A} \)); in particular, for \( \hat{\beta} \in \hat{R} \),

\[
\hat{\beta} : T \to \mathbb{F} \\
k_{\hat{\alpha}} \mapsto (\hat{\alpha}, \hat{\beta}) \quad (\hat{\alpha} \in \hat{\Phi} \setminus \{0\})
\]

is a well defined linear function.

(ii) \( \mathcal{G} \) has a weight space decomposition with respect to \( T \) with the set of weights contained in \( \{ \hat{\beta} \mid \hat{\beta} \in \hat{R} \} \).

(iii) Suppose that \( \mathcal{G} \) is centerless. Assume that \( \hat{\gamma} \in \hat{R} \setminus \{0\} \) and there are \( e \in \mathcal{G}^\hat{\gamma} \) and \( f \in \mathcal{G}^{-\hat{\gamma}} \) such that \( k := [e, f] \) satisfies

\[
[k, x] = (\hat{\beta}, \hat{\alpha}) x \quad (x \in \mathcal{G}^\hat{\beta}).
\]

If \( \{r, r_\alpha \mid \hat{\alpha} \in \hat{\Phi} \setminus \{0\} \} \subseteq \mathbb{Z} \setminus \{0\} \) and \( \hat{r} \gamma = \sum_{\hat{\alpha} \in \hat{\Phi} \setminus \{0\}} r_\alpha \hat{\alpha} \), then \( rk = \sum_{\hat{\alpha} \in \hat{\Phi} \setminus \{0\}} r_\alpha k_{\hat{\alpha}} \); in particular, \( k \in T \) and \( (e, f) \neq 0 \).

(iv) Suppose that \( \mathcal{G} \) is centerless. Assume that \( \hat{\gamma} \in \hat{R} \setminus \{0\} \) and there are \( e, x \in \mathcal{G}^\hat{\gamma} \) and \( f, y \in \mathcal{G}^{-\hat{\gamma}} \) such that \( t := [x, y] \) and \( k := [e, f] \) satisfy

\[
[t, x] = (\hat{\beta}, \hat{\alpha}) x \quad \text{and} \quad [k, x] = (\hat{\beta}, \hat{\alpha}) x \quad (x \in \mathcal{G}^\hat{\beta}).
\]

Then \( t = k \) and \( (x, y) = (e, f) \).

**Proof.** (i) The form \( \langle \cdot, \cdot \rangle \) induces the \( \mathbb{F} \)-bilinear form \( \langle \cdot, \cdot \rangle_\mathbb{F} : (\mathbb{F} \otimes_\mathbb{Z} \hat{A}) \times (\mathbb{F} \otimes_\mathbb{Z} \hat{A}) \to \mathbb{F} \) defined by

\[
(r \otimes a, s \otimes b)_\mathbb{F} := rs(a, b); \quad r, s \in \mathbb{F}, \quad a, b \in \hat{A}.
\]

This is a nondegenerate symmetric bilinear form satisfying \( \text{span}_\mathbb{F} \hat{R}^{(i)} = \{0\} \) for \( i, j \in J \) with \( i \neq j \) (see [29, Lem. 3.21]). Since \( \text{span}_\mathbb{F} \hat{\Phi} = \mathbb{Q} \otimes_\mathbb{Z} \hat{R} \) and \( \text{span}_\mathbb{F} \hat{R} = \oplus \text{span}_\mathbb{F} \hat{R}^{(j)} \), we get that

\[
\text{span}_\mathbb{F} \hat{\Phi}^{(j)} = \text{span}_\mathbb{F} \hat{R}^{(j)}.
\]

Suppose that \( j \in J \) and \( \hat{\gamma} \in \hat{\Phi}^{(j)} \). Let \( i_1, \ldots, i_m, j_1, \ldots, j_m \in I \) are such that \( \hat{\alpha}_{i_1}, \ldots, \hat{\alpha}_{i_m} \in \hat{\Phi}^{(j)} \), \( \hat{\alpha}_{j_1}, \ldots, \hat{\alpha}_{j_m} \notin \hat{\Phi}^{(j)} \) and \( k_i = r_1 k_{\hat{\alpha}_{i_1}} + \cdots + r_n k_{\hat{\alpha}_{i_m}} + s_1 k_{\hat{\alpha}_{j_1}} + \cdots + s_m k_{\hat{\alpha}_{j_m}} \) for some \( r_1, \ldots, r_n, s_1, \ldots, s_m \in \mathbb{F} \). For \( \hat{\beta} \in \hat{\Phi}^{(j)} \setminus \{0\} \), we have \( \mathcal{G}^{\hat{\beta} \neq \{0\}} \) and for \( 0 \neq x \in \mathcal{G}^{\hat{\beta}} \), we have

\[
\langle \hat{\gamma}, \hat{\beta} \rangle_\mathbb{F} x = \langle \hat{\gamma}, \hat{\beta} \rangle x \\
= \langle k_{\hat{\alpha}}, x \rangle \\
= \langle r_1 k_{\hat{\alpha}_{i_1}} + \cdots + r_n k_{\hat{\alpha}_{i_m}} + s_1 k_{\hat{\alpha}_{j_1}} + \cdots + s_m k_{\hat{\alpha}_{j_m}}, x \rangle \\
= r_1 \langle k_{\hat{\alpha}_{i_1}}, x \rangle + \cdots + r_n \langle k_{\hat{\alpha}_{i_m}}, x \rangle + s_1 \langle k_{\hat{\alpha}_{j_1}}, x \rangle + \cdots + s_m \langle k_{\hat{\alpha}_{j_m}}, x \rangle \\
= r_1 (\hat{\alpha}_{i_1}, \hat{\beta}) x + \cdots + r_n (\hat{\alpha}_{i_m}, \hat{\beta}) x + s_1 (\hat{\alpha}_{j_1}, \hat{\beta}) x + \cdots + s_m (\hat{\alpha}_{j_m}, \hat{\beta}) x \\
= r_1 (\hat{\alpha}_{i_1}, \hat{\beta}) x + \cdots + r_n (\hat{\alpha}_{i_m}, \hat{\beta}) x \\
= (r_1 \hat{\alpha}_{i_1} + \cdots + r_n \hat{\alpha}_{i_m}) \hat{\beta} x
\]

This implies that \( \hat{\gamma} = r_1 \hat{\alpha}_{i_1} + \cdots + r_n \hat{\alpha}_{i_m} \) as the form \( \langle \cdot, \cdot \rangle_\mathbb{F} \) on \( \text{span}_\mathbb{F} \hat{R}^{(j)} = \text{span}_\mathbb{F} \hat{\Phi}^{(j)} \) is nondegenerate. Now we claim that \( k_{\hat{\gamma}} = r_1 k_{\hat{\alpha}_{i_1}} + \cdots + r_n k_{\hat{\alpha}_{i_m}} \). To show this, it
is enough to prove that \((k_{i} - (r_{1}k_{\hat{\alpha}_{i_{1}}} + \cdots + r_{n}k_{\hat{\alpha}_{i_{n}}}), k_{\hat{\beta}}) = 0\) for all \(\hat{\beta} \in \tilde{\Phi} \setminus \{0\}\) as the form is nondegenerate on \(T\). Assume \(\hat{\beta} \in \tilde{\Phi} \setminus \{0\}\), then
\[
(k_{i} - (r_{1}k_{\hat{\alpha}_{i_{1}}} + \cdots + r_{n}k_{\hat{\alpha}_{i_{n}}}), k_{\hat{\beta}}) = (k_{i} - (r_{1}k_{\hat{\alpha}_{i_{1}}} + \cdots + r_{n}k_{\hat{\alpha}_{i_{n}}}), [e_{\hat{\beta}}, f_{\hat{\beta}}]) = ([k_{i} - (r_{1}k_{\hat{\alpha}_{i_{1}}} + \cdots + r_{n}k_{\hat{\alpha}_{i_{n}}}), e_{\hat{\beta}}], f_{\hat{\beta}}) = (\gamma - r_{1}\alpha_{i_{1}} + \cdots + r_{n}\alpha_{i_{n}}, \hat{\beta})(e_{\hat{\beta}}, f_{\hat{\beta}}) = 0(e_{\hat{\beta}}, f_{\hat{\beta}}) = 0.
\]
This completes the proof.

(ii) We know that \(G = \oplus_{\hat{\beta} \in \hat{R}} G^{\hat{\beta}}\). If \(x \in G^{\hat{\beta}} (\hat{\beta} \in \hat{R})\), we have \([k_{\hat{\alpha}}, x] = (\hat{\beta}, \hat{\alpha})x = \hat{\beta}(k_{\hat{\alpha}})x\) for all \(\hat{\alpha} \in \tilde{\Phi} \setminus \{0\}\) and so we have \([t, x] = \hat{\beta}(t)x\) for all \(t \in T\). So \(G\) has a weight space decomposition \(G = \oplus_{\hat{\beta} \in \hat{R}} G^{(\hat{\beta})}\) with respect to \(T\) in which for \(\hat{\beta} \in \hat{R}\), \(G^{(\hat{\beta})} = G^{\hat{\beta}}\).

(iii) We know \(G = \sum_{\hat{\beta} \in \hat{R}} G^{\hat{\beta}}\) and that for all \(a \in G^{\hat{\beta}} (\hat{\beta} \in \hat{R})\),
\[
[rk - \sum_{\hat{\alpha} \in \tilde{\Phi} \setminus \{0\}} r_{\hat{\alpha}}k_{\hat{\alpha}}, a] = r(\hat{\beta}, \hat{\alpha})a - \sum_{\hat{\alpha} \in \tilde{\Phi} \setminus \{0\}} r_{\hat{\alpha}}(\hat{\beta}, \hat{\alpha})a = (\hat{\beta}, r\hat{\gamma}) - \sum_{\hat{\alpha} \in \tilde{\Phi} \setminus \{0\}} r_{\hat{\alpha}}\hat{\alpha}a = 0.
\]
This means that \(rk - \sum_{\hat{\alpha} \in \tilde{\Phi} \setminus \{0\}} r_{\hat{\alpha}}k_{\hat{\alpha}}\) is an element of the center of \(G\) and so it is zero, i.e. \(rk = \sum_{\hat{\alpha} \in \tilde{\Phi} \setminus \{0\}} r_{\hat{\alpha}}k_{\hat{\alpha}}\); in particular, \(k \in T\). Now to the contrary, assume \((e, f) = 0\), then for each \(\hat{\alpha} \in \tilde{\Phi} \setminus \{0\}\),
\[
(k, k_{\hat{\alpha}}) = ([e, f], k_{\hat{\alpha}}) = (e, [f, k_{\hat{\alpha}}]) = (\hat{\alpha}, \hat{\gamma})(e, f) = 0.
\]
This contradicts the fact that the form on \(T\) is nondegenerate.

(iv) As \(G\) is centerless, it is immediate that \(t = k\). We shall show that \((e, f) = (x, y)\). Since \(\hat{\gamma} \neq 0\), there is \(\hat{\alpha} \in \tilde{\Phi}\) with \((\hat{\alpha}, \hat{\gamma}) \neq 0\). Now we have
\[
(e, f)(\hat{\gamma}, \hat{\alpha}) = ((\hat{\gamma}, \hat{\alpha})e, f) = ([k_{\hat{\alpha}}, e], f) = (k_{\hat{\alpha}}, [e, f]) = (k_{\hat{\alpha}}, k) = (k, k_{\hat{\alpha}}) = (k, [e_{\hat{\alpha}}, f_{\hat{\alpha}}]) = ([k_{\hat{\alpha}}, e_{\hat{\alpha}}], f_{\hat{\alpha}}) = (\hat{\gamma}, \hat{\alpha})(e_{\hat{\alpha}}, f_{\hat{\alpha}}).
\]
This implies that \((e, f) = (e_{\hat{\alpha}}, f_{\hat{\alpha}})\). Similarly \((x, y) = (e_{\hat{\alpha}}, f_{\hat{\alpha}})\). This completes the proof. \(\square\)

**Theorem 2.7.** Suppose that \((\hat{A}, (\cdot, \cdot), \hat{R})\) is a locally finite root supersystem and \(\Lambda\) is a torsion free additive abelian group. Suppose that \(G = \oplus_{\lambda \in \Lambda} \oplus_{\hat{\beta} \in \hat{R}} \lambda G^{\hat{\beta}}\) is a centerless \((\hat{R}, \Lambda)\)-graded Lie superalgebra, with a grading subsystem \(\tilde{\Phi}\), equipped with an invariant nondegenerate even supersymmetric bilinear form \((\cdot, \cdot)\). Suppose that

- for \(\lambda, \mu \in \Lambda\) with \(\lambda + \mu \neq 0\), \((\lambda G, \mu G) = \{0\}\),
- the form is nondegenerate on the span of a set of toral elements of \(G\),
- for \(\lambda \in \Lambda\) with \(\lambda G^{0}_{i} := G_{i} \cap \lambda G \cap G^{0} \neq \{0\}\) \((i = 0, 1)\), there are \(e \in \lambda G^{0}_{i}\) and \(f \in -\lambda G^{0}_{i}\) such that \([e, f]_{0} = 0\) and \((e, f) \neq 0\).
for $\dot{\alpha} \in \dot{\mathcal{R}} \setminus \{0\}$ and $\lambda \in \Lambda$ with $\lambda G^\dot{\alpha}_i := G_i \cap \lambda \mathcal{G} \cap G^\dot{\alpha} \neq \{0\}$ ($i = 0, 1$), there are $e \in \lambda G^\dot{\alpha}_i$ and $f \in -\lambda G^{-\dot{\alpha}}$ such that $k := [e, f] \in \mathcal{G}_0 \setminus \{0\}$ and for $\dot{\beta} \in \dot{\mathcal{R}}$ and $x \in G^\dot{\beta}$, $[k, x] = (\dot{\beta}, \dot{\alpha})x$.

then $\mathcal{G}$ is isomorphic to the core of an extended affine Lie superalgebra modulo the center.

**Proof.** Set $\mathcal{V} := \mathbb{F} \otimes_2 \Lambda$. Identify $\Lambda$ with a subset of $\mathcal{V}$ and fix a basis $\{\lambda_i \mid i \in I\} \subseteq \Lambda$ of $\mathcal{V}$. Suppose that $\mathcal{V}^\dagger$ is the restricted dual of $\mathcal{V}$ with respect to this basis. We suppose $\{d_i \mid i \in I\}$ is the corresponding basis for $\mathcal{V}^\dagger$. Consider $d_i$ ($i \in I$) as a derivation of $\mathcal{G}$ mapping $x \in \lambda \mathcal{G}$ to $d_i(\lambda)x$ for all $\lambda \in \Lambda$. Set

$$\mathcal{L} := \mathcal{G} \oplus \mathcal{V} \oplus \mathcal{V}^\dagger$$

and define

$$\begin{align*}
deg(v) &= 0; \quad v \in \mathcal{V} \oplus \mathcal{V}^\dagger \\
- [x, d] &= [d, x] := d(\lambda)x, \quad (d \in \mathcal{V}^\dagger, x \in \mathcal{G}), \\
[\mathcal{L}, \mathcal{V}] &= \{\mathcal{V}, \mathcal{L}\} = [\mathcal{V}^\dagger, \mathcal{V}^\dagger] := \{0\}, \\
[x, y] &= := [x, y]_\mathcal{G} + \sum_{i \in I} (d_i(x), y)\lambda_i, \quad (x, y \in \mathcal{G}),
\end{align*}$$

where by $[,]_\mathcal{G}$, we mean the Lie bracket on $\mathcal{G}$. We next extend the form on $\mathcal{G}$ to a bilinear form on $\mathcal{L}$ by

$$\begin{align*}
(\mathcal{V}, \mathcal{V}) &= \{\mathcal{V}^\dagger, \mathcal{V}^\dagger\} = \{\mathcal{V}^\dagger, \mathcal{G}\} := \{0\}, \\
(v, d) &= (d, v) := d(v), \quad d \in \mathcal{V}^\dagger, v \in \mathcal{V}.
\end{align*}$$

Then $\mathcal{L} = \mathcal{L}_0 \oplus \mathcal{L}_1$, where $\mathcal{L}_0 := \mathcal{G}_0 \oplus \mathcal{V} \oplus \mathcal{V}^\dagger$ and $\mathcal{L}_1 := \mathcal{G}_1^\dagger$, together with the Lie bracket $[,]$ is a Lie superalgebra and $(, , )$ is an invariant nondegenerate even supersymmetric bilinear form.

For $\dot{\alpha} \in \dot{\Phi} \setminus \{0\}$, we fix $e_{\dot{\alpha}} \in 0^\mathcal{G}^\dot{\alpha}$ and $f_{\dot{\alpha}} \in 0\mathcal{G}^{-\dot{\alpha}}$ such that $k_{\dot{\alpha}} = [e_{\dot{\alpha}}, f_{\dot{\alpha}}]$ and that the form on

$$T := \text{span}_\mathbb{F}\{k_{\dot{\alpha}} \mid \dot{\alpha} \in \dot{\Phi} \setminus \{0\}\}$$

is nondegenerate. We next set

$$\mathcal{H} := T \oplus \mathcal{V} \oplus \mathcal{V}^\dagger$$

and note that the form restricted to $\mathcal{H}$ is nondegenerate. We identify $\mathcal{H}^*$ with $T^* \oplus \mathcal{V}^* \oplus (\mathcal{V}^\dagger)^*$ in the usual manner. We also consider $\lambda \in \mathcal{V}$ as an element of $\mathcal{H}^*$ by $\lambda(t + v + d) = d(\lambda)$. We know that

$$\begin{align*}
\mathcal{L}_0 &= \sum_{\lambda \in \Lambda} \sum_{\dot{\alpha} \in \dot{\mathcal{R}}} \lambda G^\dot{\alpha}_0 \oplus \mathcal{V} \oplus \mathcal{V}^\dagger \\
\mathcal{L}_1 &= \sum_{\lambda \in \Lambda} \sum_{\dot{\alpha} \in \dot{\mathcal{R}}} \lambda G^\dot{\alpha}_1.
\end{align*}$$

For $i \in \{0, 1\}$, $t \in T$, $v \in \mathcal{V}$, $d \in \mathcal{V}^\dagger$, $\dot{\beta} \in \dot{\mathcal{R}}$, $\lambda \in \Lambda$ and $x \in \lambda G^\dot{\beta}_i$, we have using Lemma 2.6(ii) that

$$\begin{align*}
[t + v + d, x] &= [t, x]_\mathcal{G} + [d, x] = (\dot{\beta} + \lambda)(t + v + d)x, \\
[t + v + d, \mathcal{V} \oplus \mathcal{V}^\dagger] &= \{0\},
\end{align*}$$

so for $i = 0, 1$, $\mathcal{L}_i$ has a weight space decomposition with respect to $\mathcal{H}$ with the set of weights $\{\dot{\beta} + \lambda \mid \dot{\beta} \in \dot{\mathcal{R}}, \lambda \in \Lambda, \lambda G^\dot{\beta}_i \neq \{0\}\}$. Now suppose $i \in \{0, 1\}$, $\dot{\beta} \in \dot{\mathcal{R}}$, $\lambda \in \Lambda$ with $\dot{\beta} + \lambda \neq 0$ and $\mathcal{L}_i^{\dot{\beta} + \lambda} \neq \{0\}$. So if $\dot{\beta} \neq 0$, there are $e \in \lambda G^\dot{\beta}_i$ and $f \in -\lambda G^{-\dot{\beta}}$ such that $k := [e, f] \in \mathcal{G}_0 \setminus \{0\}$ and for $x \in \mathcal{G}^\dot{\beta}$, $[k, x] = (\dot{\beta}, \dot{\alpha})x$. 

But since \( \text{span}_\mathbb{Q} \Phi = \mathbb{Q} \otimes \mathbb{Q} \text{span}_\mathbb{Q} \hat{R} \), there is a nonzero integer \( r \in \mathbb{Z} \) such that \( r\hat{\beta} = \sum_{\alpha \in \Phi \backslash \{0\}} r_\alpha \alpha \). So \( k = \frac{1}{r} \sum_{\alpha \in \Phi \backslash \{0\}} r_\alpha k_\alpha \in T \) by Lemma 2.6. This implies that \( [e, f] \in H \backslash \{0\} \). Also if \( \beta = 0 \), take \( e \in \lambda \mathcal{G}_i^0 \) and \( f \in -\lambda \mathcal{G}_i^0 \) such that \( [e, f] = 0 \) and \( (e, f) \neq 0 \), then \( [e, f] \in H \backslash \{0\} \). Therefore there are \( e \in \mathcal{L}_i^{\hat{\beta}+\lambda} = \lambda \mathcal{G}_i^{\beta} \) and \( f \in \mathcal{L}_i^{-\hat{\beta}-\lambda} = -\lambda \mathcal{G}_i^{-\beta} \) with \( 0 \neq [e, f] \in H \).

Take \( R \) to be the root system of \( \mathcal{L} \) with respect to \( H \) and suppose \( \hat{\alpha} \in \hat{R} \) and \( \lambda \in \Lambda \) with \( \hat{\alpha} + \lambda \in R \). If \( \hat{\alpha} = 0 \), then it is easy to see that \( t_{\hat{\alpha}+\lambda} = \lambda \) in which \( t_{\hat{\alpha}+\lambda} \) as before is the unique element of \( H \) representing \( \hat{\alpha} + \lambda \) through the form \( \langle \cdot, \cdot \rangle \). Also if \( \hat{\alpha} \neq 0 \), we fix \( e \in \lambda \mathcal{G}_i^0 \) and \( f \in -\lambda \mathcal{G}_i^{-\hat{\alpha}} \) such that for \( k := [e, f] \in \mathcal{G}_i^0 \backslash \{0\} \) and for all \( x \in \mathcal{G}_i^\beta \ (\beta \in R^\times) [k, x] = (\hat{\alpha}, \beta)x \). Then considering Lemma 2.6 it is easily verified that \( t_{\hat{\alpha}+\lambda} = (e, f)^{-1}k + \lambda \). Now it follows that \( R^0 = R \cap \Lambda \) and \( R^\times = \{ \hat{\beta} + \lambda \mid \hat{\beta} \in \hat{R}^\times, \lambda \in \Lambda, \lambda \mathcal{G}_i^{\hat{\beta}} \neq \{0\} \} \). We next show that \( adx \) is locally nilpotent for \( x \in \lambda \mathcal{G}_i^0 = \mathcal{L}_i^{\hat{\beta}+\lambda} \ (\hat{\alpha} \in \hat{R}^\times \) and \( \lambda \in \Lambda \) with \( \hat{\alpha} + \lambda \in R \). Let \( v \in V \) and \( d \in V^\dagger \), then \( adx(v) = 0 \) and if \( \lambda = 0 \), \( adx(d) = 0 \). Next suppose that \( \lambda \neq 0 \), then we have

\[
(adx)^3(d) = -\lambda(d)(adx)^2(x) = -\lambda(d)[x, [x, x]] \\
= -\lambda(d)[x, [x, x]]_\varphi \\
= -\lambda(d)([x, [x, x]]_\varphi + \sum_{i \in I} (d_i(x), [x, x])_\varphi)_i \\
= -\lambda(d)[x, [x, x]]_\varphi \in \mathcal{G}^{3\lambda} = \{0\}.
\]

Also for \( \hat{\beta} \in \hat{R}, \mu \in \Lambda \) and \( y \in \mu \mathcal{G}_i^\lambda \), since \( \hat{R} \) is a locally finite root supersystem, \( \{k\alpha + \hat{\beta} \mid k \in \mathbb{Z}\} \cap \hat{R} \) is a finite set. Fix a positive integer \( N \) such that for \( m \geq N \), \( m\hat{\alpha} + \hat{\beta} \notin \hat{R} \). If \( \lambda = 0 \), we have \( (adx)^N(y) = (ad\varphi x)^N(y) \in \mathcal{G}_{N\hat{\alpha}+\hat{\beta}} = \{0\} \) in which \( ad \varphi \) denotes the adjoint representation of \( \mathcal{G} \). If \( \lambda \neq 0 \), we choose a positive integer \( n > N \) such that \( n\lambda + \mu \neq 0 \), then

\[
(adx)^n(y) = (ad\varphi x)^n(y) + \sum_{i \in I} (d_i(x), (ad\varphi x)^{n-1}(y))_i \\
= (ad\varphi x)^n(y) \in \mathcal{G}^{n\lambda+\hat{\beta}} = \{0\}.
\]

Therefore \( adx \) is locally nilpotent. Thus \( (\mathcal{L}, \langle \cdot, \cdot \rangle, H) \) is an extended affine Lie superalgebra with root system \( R = \{ \hat{\beta} + \lambda \mid \hat{\beta} \in \hat{R}, \lambda \in \Lambda, \mathcal{G}^{\hat{\beta}} \neq \{0\} \} \). We now show that \( \mathcal{L}_c / Z(\mathcal{L}_c) \) is a Lie superalgebra isomorphic to \( \mathcal{G} \). We know that

\[
\mathcal{L}_c = \sum_{\hat{\alpha} \in \hat{R}^\times, \lambda \in \Lambda} \lambda \mathcal{G}_i^{\hat{\alpha}} + \sum_{\hat{\alpha} \in \hat{R}^\times, \lambda \in \Lambda} [\lambda \mathcal{G}_i^{\hat{\alpha}}, \mu \mathcal{G}_i^{-\hat{\alpha}}] \subseteq \mathcal{G} \oplus V.
\]

Take \( \Pi \) to be the restriction of the canonical projection map \( \mathcal{L} \rightarrow \mathcal{G} \) to \( \mathcal{L}_c \) with respect to the decomposition \( \mathcal{L} = \mathcal{G} \oplus V \oplus V^\dagger \). Since \( \mathcal{G} \subseteq \mathcal{L}_c \) for all \( \hat{\alpha} \in \hat{R} \backslash \{0\} \) and \( \mathcal{G}^0 = \sum_{\hat{\alpha} \in \hat{R} \backslash \{0\}} [\mathcal{G}_i^{\hat{\alpha}}, \mathcal{G}_i^{-\hat{\alpha}}]_\varphi, \Pi \) is surjective. Also if \( x \in \mathcal{G} \) and \( v \in V \) are such that \( x + v \in Z(\mathcal{L}_c) \), then \( [x, v, \mathcal{G}] = \{0\} \) for all \( \hat{\alpha} \in \hat{R} \backslash \{0\} \). So \( [x, \mathcal{G}] = \{0\} \) for all \( \hat{\alpha} \in \hat{R} \backslash \{0\} \). Then it follows that \( x \in Z(\mathcal{G}) = \{0\} \). Therefore \( Z(\mathcal{L}_c) = \mathcal{L}_c \cap V = ker\Pi \). This implies that \( \mathcal{L}_c \) is isomorphic to \( \mathcal{G} \).

\[\square\]

**Example 2.10.** Suppose that \( F = \mathbb{C} \) and take \( I, J \) to be two disjoint index sets with cardinal numbers greater than 2. We use the same notations as in Subsection 1.1 in
For $j, k \in \{0\} \cup I \cup J \cup \bar{J}$, consider $e_{j,k}$ and $\mathfrak{gl}$ as in $[1.2]$ and $[1.3]$ and for $T = \sum_{j,k} r_{j,k} e_{j,k}$, set $\bar{T} := \sum_{j,k} \bar{r}_{j,k} e_{j,k}$. Now set

$$L_i := \{X \in \mathfrak{gl}_i \mid (Xv,w) = -(-1)^{|X||v|}(v, \bar{X}w); \forall v, w \in \mathfrak{u}\}; i = 0, 1$$

$$\mathcal{L} = \mathcal{L}_0 \oplus \mathcal{L}_1$$

$$\mathcal{G} := \mathcal{L} \cap \text{span}\{e_{j,k} \mid j, k \in \{0\} \cup I \cup \bar{I} \cup J \cup \bar{J}\},$$

$$\mathcal{H} := \text{span}\{h_t := e_{t,t} - e_{t,\bar{t}}, d_k := e_{k,k} - e_{\bar{k},k} \mid t \in I, k \in J\}.$$  

For $i \in I$ and $j \in J$, define

$$e_i : \mathcal{H} \longrightarrow \mathbb{R}$$

$$h_t \mapsto \delta_{t,t}, \quad d_k \mapsto 0,$$

$$\delta_t : \mathcal{H} \longrightarrow \mathbb{R}$$

$$h_t \mapsto 0, \quad d_k \mapsto \delta_{j,k}, \quad (t \in I, k \in J).$$

One can see that with respect to $\mathcal{H}$, $\mathcal{L}$ has a weight space decomposition $\mathcal{L} = \bigoplus_{n}^{\alpha \in R} \mathcal{L}^{\alpha}$ with the set of weights

$$R := \{\pm \epsilon_r, \pm (\epsilon_r \pm \epsilon_s), \pm \delta_p, \pm (\delta_p \pm \delta_q), \pm (\epsilon_r \pm \delta_p) \mid 1 \leq r, s \leq m, 1 \leq p, q \leq n\}$$

and for $1 \leq r \neq s \leq m$ and $1 \leq p \neq q \leq n$,

$$\mathcal{L}^{\alpha_{r,s}} = \text{span}\{i^{\alpha}(\epsilon_r,0) - (-1)^{\alpha}\epsilon_0,0) \mid \alpha = 0, 1\},$$

$$\mathcal{L}^{\alpha_{r-s}} = \text{span}\{i^{\alpha}(\epsilon_r,0) - (-1)^{\alpha}\epsilon_0,0) \mid \alpha = 0, 1\},$$

$$\mathcal{L}^{2\epsilon_r} = \text{span}\{i^{2\epsilon_r} \epsilon_r,0\},$$

$$\mathcal{L}^{2\epsilon_r} = \text{span}\{i^{2\epsilon_r} \epsilon_r,0\},$$

$$\mathcal{L}^{2\epsilon_r} = \text{span}\{i^{2\epsilon_r} \epsilon_r,0\},$$

and it is easy to see that the Lie superalgebra $\mathfrak{L} := \sum_{\alpha \in R} \mathcal{L}^{\alpha} + \sum_{\alpha \in R} [\mathcal{L}^{\alpha}, \mathcal{L}^{-\alpha}]$ is a $B(I, J)$-graded Lie superalgebra with grading subsystem $(R_{re})_{red}$.

3. **BC($I, J$)-Graded Lie Superalgebras**

In this section, we illustrate the structure of Lie superalgebras graded by the locally finite root supersystem $BC(I, J)$. Throughout this section, we use the same
notations as in Section 1.1; in particular, we recall $\mathfrak{g}$ as well as $\mathfrak{s}$ from (1.3), $\Delta_u$ from (1.6) and $R, \Delta_x$ from (1.7). We set
\[
\Psi := \{ \pm \epsilon_i \pm \epsilon_j, \pm \epsilon_i, \pm \delta_p \pm \delta_q, \pm \epsilon_i, \pm \delta_p \mid i \in I, j \in J \} = R \cup \{ \pm 2 \epsilon_i \mid i \in I \};
\]
in fact $\Psi$ is a locally finite root supersystem of type $BC(I, J)$. Suppose that $\mathcal{L}$ is a Lie superalgebra such that
\[
(3.1)
\]

- $\mathcal{L}$ contains $\mathfrak{g}$ as a subalgebra,
- $\mathcal{L}$ is equipped with a weight space decomposition $\mathcal{L} = \bigoplus_{\alpha \in \Psi} \mathcal{L}^\alpha$, with respect to $\mathfrak{h}$,
- $\mathcal{L}^0 = \sum_{\alpha \in \Psi \setminus \{0\}} [\mathcal{L}^\alpha, \mathcal{L}^{-\alpha}]$.

It is easy to see that (3.1) is just a generalization of the notion of root graded Lie superalgebra in the sense of [7] by switching from finite root supersystems to locally finite root supersystems. In this section, we study the structure of a Lie superalgebra $\mathcal{L}$ satisfying (3.1). Throughout this section we suppose $\mathbb{F}$ is an algebraically closed field of characteristic zero; we also make a convention that for a map $f$ defined on a set $X$, by $x^f$, for $x \in X$, we mean the image of $x$ under $f$.

### 3.1. Some Conventions

Suppose that $\mathfrak{a}$ is an associative superalgebra and $\eta$ is a superinvolution of $\mathfrak{a}$, i.e., $\eta$ is an even linear map with $\eta^2 = id$ and $\eta(ab) = (-1)^{|a||b|}\eta(b)\eta(a)$ for all $a, b \in \mathfrak{a}$. Next we assume $\mathcal{C}$ is an associative $\mathfrak{a}$-supermodule and $\chi : \mathcal{C} \times \mathcal{C} \rightarrow \mathfrak{a}$ is a superhermitian $\mathfrak{a}$-form of $\mathcal{C}$, in the sense that $\chi$ is an even bilinear form satisfying
\[
\chi(x, y)^\eta = (-1)^{|x||y|}\chi(y, x) \quad \text{and} \quad \chi(ax, y) = a\chi(x, y)
\]
for all $x, y \in \mathcal{C}$ and $a \in \mathfrak{a}$. Then $b := b(a, \mathcal{C}) := \mathfrak{a} \oplus \mathcal{C}$ together with
\[
(a + c)(a' + c') = (a \cdot a' + 2\chi(c, c')) = (a \cdot c' + (-1)^{|a||c|}\chi(a')^\eta \cdot c)
\]
is a superalgebra. We set
\[
\mathcal{A} := \{ \alpha \in \mathfrak{a} \mid \alpha^\eta = \alpha \} \quad \text{and} \quad \mathcal{B} := \{ \alpha \in \mathfrak{a} \mid \alpha^\eta = -\alpha \}
\]
and note that
\[
\mathfrak{a} = \mathcal{A} \oplus \mathcal{B}.
\]

We next define
\[
\circ : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{A} \quad (c, c') \mapsto \frac{1}{2}(\chi(c, c') + (-1)^{|c||c'|}\chi(c', c))
\]
\[
\odot : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{B} \quad (c, c') \mapsto \frac{1}{2}(\chi(c, c') - (-1)^{|c||c'|}\chi(c', c)).
\]
Finally for $\beta_1 = a_1 + b_1 + c_1, \beta_2 = a_2 + b_2 + c_2 \in \mathcal{A} \oplus \mathcal{B} \oplus \mathcal{C}$, we set
\[
(3.2) \quad \beta_{\beta_1, \beta_2}^* := [a_1, a_2] + [b_1, b_2] + 2c_1 \odot c_2, \quad \beta_1^* := c_1 \quad \text{and} \quad \beta_2^* := c_2.
\]
3.2. **Structure Theorem.** We suppose $|I|, |J| > 4$ and fix a nonempty subset $I_0$ of $I$ of finite cardinal number $m > 3$ as well as a subset $J_0$ of $J$ of finite cardinal number $n > 3$ and set

\[(3.3) \Phi := \{ \pm \varepsilon_i \pm \varepsilon_j, \pm \varepsilon_i, \pm \delta_p \pm \delta_q, \pm \delta_p, \pm \varepsilon_i \pm \delta_p \mid i \in I_0, j \in J_0 \}, \]

\[R_{m,n} := \Phi \setminus \{ \pm 2\varepsilon_i \mid i \in I_0 \}. \]

We next define the linear endomorphism $id_{m,n}$ on $u$ by

\[id_{m,n} : u \rightarrow u, \]

\[v_0 \mapsto v_0, v_i \mapsto v_i, v_i \mapsto v_i, v_j \mapsto 0, v_j \mapsto 0, \]

\[(i \in I_0 \cup J_0, j \in I \cup J \setminus (I_0 \cup J_0)) \]

and for $u, v \in u$ and $x, y \in g \cup s$, define

\[[u, v] : u \rightarrow u; \ w \mapsto (v, w)u + (-1)^{|u||v|}(u, w)v - \frac{2(u, v)}{2m+1-2n} id_{m,n}(w); \ w \in u,\]

\[u \circ v : u \rightarrow u; \ w \mapsto (v, w)u - (-1)^{|u||v|}(u, w)v; \ w \in u, \]

\[x \circ y := xy + (-1)^{|x||y|}yx - \frac{2str(xy)}{2m+1-2n} id_{m,n}. \]

**Theorem 3.4.** Suppose that $\mathfrak{L}$ is a Lie superalgebra satisfying the following:

- $\mathfrak{L}$ contains $g$ as a subalgebra,
- $\mathfrak{L}$ is equipped with a weight space decomposition $\mathfrak{L} = \bigoplus_{\alpha \in \Phi} \mathfrak{L}^\alpha$, with respect to $h$,
- $\mathfrak{L}^0 = \sum_{\alpha \in \Phi \setminus \{0\}} [\mathfrak{L}^\alpha, \mathfrak{L}^{-\alpha}].$

Then there are a subsuperalgebra $\mathcal{D}$ of $\mathfrak{L}$, superspaces $\mathcal{A}, \mathcal{B}, \mathcal{C}$, even bilinear maps

\[\cdot : a \times a \rightarrow a \quad \cdot : a \times C \rightarrow C \quad \chi : C \times C \rightarrow a \quad \langle \cdot, \cdot \rangle : b \times b \rightarrow \mathcal{D} \]

in which $b := a \oplus C$, and linear maps

\[\eta : a \rightarrow a \quad \text{and} \quad \phi : \mathcal{D} \rightarrow End(b) \]

such that $(a, \cdot)$ is an associative superalgebra, $(\mathcal{C}, \cdot)$ is an associative $a$-module, $\eta$ is a superinvolution and $\chi$ is a superhermitian $a$-form with the following properties:

- $(\cdot, \cdot)$ is surjective, supersymmetric and satisfy $\langle A, B \rangle = \langle A, C \rangle = \langle B, C \rangle = \{0\}$, where $A$ and $B$ are respectively fixed and skew-fixed points of $A$ under the map $\eta$,
- considering the superalgebraic structure on $b$ as constructed in Subsection 3.1 for each $d \in \mathcal{D}$, we have $\phi(d)$ is a superderivation of $b$; i.e., $\mathcal{D}$ acts on $b$ as superderivations,
- $dA \subseteq A, dB \subseteq B$ and $dC \subseteq C$, for all $d \in \mathcal{D}$,
- $[d, (\beta, \beta')] = \langle d\beta, \beta' \rangle + (-1)^{|d||\beta'|}(\beta, d\beta'),$
- $\sum (\alpha) (-1)^{|\beta||\beta'|} \langle \beta_1, \beta_2 \beta_3 \rangle = 0,$
- $\langle \alpha, \alpha' \rangle \alpha'' = \frac{1}{2m+1-2n} [\alpha, \alpha'] - [\alpha, \alpha']^g, \alpha'',$
- $\langle \alpha, \alpha' \rangle c = \frac{1}{2m+1-2n} [\alpha, \alpha'] - [\alpha, \alpha']^g c,$
- $\langle c, c' \rangle \alpha = \frac{1}{2m+1-2n} [\chi(c, c') - \chi(c, c')^g, \alpha].$
\( (c, c')e'' = \frac{1}{2m+1-2n} (\chi(c, c') - \chi(c, c')\eta) \cdot e'' + (-1)^{|c||c'|+|e''|} \chi(c', c'') \eta \cdot c - (-1)^{|c'||c|} \chi(c, c)\eta \cdot c'. \)

Moreover, we have the following:

(i) There are subsuperspaces \( \mathcal{L}^1, \mathcal{L}^2 \) and \( \mathcal{L}^3 \) of \( \mathcal{L} \) isomorphic to \( g \otimes A, s \otimes B \) and \( u \otimes C \) respectively such that

\[ \mathcal{L} = (\mathcal{L}^1 \oplus \mathcal{L}^2 \oplus \mathcal{L}^3) + D. \]

Furthermore, if either \( |I| = m \) and \( |J| = n \) or \( I \cup J \) is an infinite set, we have

\[ \mathcal{L} = \mathcal{L}^1 \oplus \mathcal{L}^2 \oplus \mathcal{L}^3 \oplus D, \]

more precisely, in these cases \( \mathcal{L} \) can be identified with

\[(g \otimes A) \oplus (s \otimes B) \oplus (u \otimes C) \oplus D. \]

(ii) Identify \( \mathcal{L}^1, \mathcal{L}^2 \) and \( \mathcal{L}^3 \) with \( g \otimes A, s \otimes B \) and \( u \otimes C \) respectively, the Lie bracket on \( \mathcal{L} \) is given by the following:

\[
\begin{align*}
[x \otimes a, y \otimes a'] &= (-1)^{|a||y|}( [x, y] \otimes \frac{1}{2}(a \circ a') + (x \circ y) \otimes \frac{1}{2}[a, a'] + str(xy)(a, a')), \\
[x \otimes a, e \otimes b] &= (-1)^{|a||e|}((x \circ e) \otimes \frac{1}{2}[a, b] + [x, e] \otimes \frac{1}{2}(a \circ b)), \\
[e \otimes b, f \otimes b'] &= (-1)^{|e||f|}( [e, f] \otimes \frac{1}{2}(b \circ b') + (e \circ f) \otimes \frac{1}{2}[b, b'] + str(ef)(b, b')), \\
[x \otimes a, u \otimes c] &= (-1)^{|a||u|}xu \otimes a \cdot c, \\
[e \otimes b, u \otimes c] &= (-1)^{|b||u|}cu \otimes b \cdot c, \\
[u \otimes c, v \otimes c'] &= (-1)^{|c||c'|}((u \circ v) \otimes (c \circ c') + [u, v] \otimes (c \circ c') + (u, v)(c, c')) \\
[\langle \beta_1, \beta_2 \rangle, \langle \beta'_1, \beta'_2 \rangle] &= \langle \langle \beta_1, \beta_2 \rangle \beta'_1, \beta'_2 \rangle + (-1)^{|\beta_1||\beta_2|+|\beta'_1||\beta'_2|} \langle \beta_1, \beta_2 \rangle \langle \beta'_1, \beta'_2 \rangle, \\
[\langle \beta_1, \beta_2 \rangle, x \otimes a] &= (-1)^{|\beta_1||x||+|\beta_2||x|} (id_{m,n} \otimes \langle \beta_1, \beta_2 \rangle \circ a) + (id_{m,n} \circ x) \otimes \langle \beta_1, \beta_2 \rangle a \\
[\langle \beta_1, \beta_2 \rangle, e \otimes b] &= (-1)^{|\beta_1||e||+|\beta_2||e|} (id_{m,n} \otimes \langle \beta_1, \beta_2 \rangle \circ b) + (id_{m,n} \circ e) \otimes \langle \beta_1, \beta_2 \rangle b) \\
[\langle \beta_1, \beta_2 \rangle, u \otimes c] &= (-1)^{|\beta_1||u||+|\beta_2||u|} (id_{m,n} \otimes \langle \beta_1, \beta_2 \rangle c) + (-1)^{|\beta_1||u||+|\beta_2||u|} u \otimes \langle \beta_1, \beta_2 \rangle c + \langle \beta_1, \beta_2 \rangle c. \\
\end{align*}
\]

Remark 3.6. We mention that if \( |I| = m \) and \( |J| = n \), then the last three Lie brackets in the above display will be converted to the following ones:

\[
\begin{align*}
[\langle \beta_1, \beta_2 \rangle, x \otimes a] &= (-1)^{|\beta_1||x|+|\beta_2||x|} \circ x \otimes \langle \beta_1, \beta_2 \rangle a \\
(3.7) \quad [\langle \beta_1, \beta_2 \rangle, e \otimes b] &= (-1)^{|\beta_1||e|+|\beta_2||e|} e \circ \langle \beta_1, \beta_2 \rangle b \\
[\langle \beta_1, \beta_2 \rangle, u \otimes c] &= (-1)^{|\beta_1||u|+|\beta_2||u|} u \otimes \langle \beta_1, \beta_2 \rangle c. \\
\end{align*}
\]

To prove Theorem 3.3, we first carry out the proof for the case that \( |I|, |J| < \infty \); at the first step, we suppose \( I = I_0 \) and \( J = J_0 \).
3.2.1. Finite Case-The First Step. In this subsection, we assume \( I = I_0, J = J_0 \) and that \( \mathcal{L} \) is a Lie superalgebra satisfying (3.1). Consider \( \mathcal{L} \) as a \( \mathfrak{g} \)-module via the adjoint representation, then \( \mathcal{L} \) is a locally finite \( \mathfrak{g} \)-module, i.e., any finite subset of \( \mathcal{L} \) generates a finite dimensional \( \mathfrak{g} \)-submodule (see [9] Lem. 2.2). Therefore, it is a summation of finite dimensional \( \mathfrak{g} \)-submodules. Using Corollary 1.18, \( \mathcal{L} \) is completely reducible such that each of its irreducible components is either isomorphic to one of \( \mathfrak{g} \)-modules \( \mathfrak{g}, \mathfrak{u}, \mathfrak{s} \) or it is a trivial \( \mathfrak{g} \)-module. Now collecting the isomorphic \( \mathfrak{g} \)-submodules of the same parity, we may assume that as a vector space, \( \mathcal{L} \) is isomorphic to

\[
(\mathfrak{g} \otimes \mathfrak{A}_0) \oplus (\mathfrak{g} \otimes \mathfrak{A}_1) \oplus (\mathfrak{s} \otimes \mathfrak{B}_0) \oplus (\mathfrak{s} \otimes \mathfrak{B}_1) \oplus (\mathfrak{u} \otimes \mathfrak{C}_0) \oplus (\mathfrak{u} \otimes \mathfrak{C}_1) \oplus \mathfrak{D};
\]

in which \( \mathfrak{A}_0, \mathfrak{A}_1, \mathfrak{B}_0, \mathfrak{B}_1, \mathfrak{C}_0 \) and \( \mathfrak{C}_1 \) are vector spaces and \( \mathfrak{D} \) is the centralizer of \( \mathfrak{G} \) in \( \mathcal{L} \); in particular, \( \mathfrak{D} \) is a subsuperalgebra of \( \mathcal{L} \). Setting

\[
\mathfrak{A} := \mathfrak{A}_0 \oplus \mathfrak{A}_1, \quad \mathfrak{B} := \mathfrak{B}_0 \oplus \mathfrak{B}_1, \quad \mathfrak{C} := \mathfrak{C}_0 \oplus \mathfrak{C}_1, \quad \mathfrak{D} := \mathfrak{D}_0 \oplus \mathfrak{D}_1,
\]

we can consider

\[
\mathcal{L} = (\mathfrak{g} \otimes \mathfrak{A}) \oplus (\mathfrak{s} \otimes \mathfrak{B}) \oplus (\mathfrak{u} \otimes \mathfrak{C}) \oplus \mathfrak{D}.
\]

Now using the same argument as in [9 § 5], one can see that the Lie superalgebraic structure on \( \mathcal{L} \) induces a superalgebraic structure on \( \mathfrak{A} \oplus \mathfrak{B} \oplus \mathfrak{C} \) and that the stated properties in Theorem 3.4 are fulfilled.

3.2.2. Finite Case-Compatibility of Subsuperalgebras. Throughout this subsection, we assume that \( m' > m, n' > n \), \( I = \{1, \ldots, m'\}, J = \{1, \ldots, n'\} \) and \( I_0 = \{1, \ldots, m\}, J_0 = \{1, \ldots, n\} \). We also assume

\[
\mathcal{L} := \sum_{\alpha \in \Phi \setminus \{0\}} \mathcal{L}^\alpha \oplus \sum_{\alpha \in \Phi \setminus \{0\}} [\mathcal{L}^\alpha, \mathcal{L}^{-\alpha}]
\]

is a Lie superalgebra satisfying (3.1). Consider \( \mathcal{L} \) as a \( \mathfrak{g} \)-module. As in the previous subsection, it follows from Corollary 1.18 that \( \mathcal{L} \) is decomposed into irreducible submodules, more precisely,

\[
\mathcal{L} = \sum_{i \in I} \mathfrak{g}^{(i)} \oplus \sum_{j \in J} \mathfrak{y}^{(j)} \oplus \sum_{t \in T} \mathfrak{s}^{(t)} \oplus \mathfrak{E}
\]

in which \( \mathfrak{g}^{(i)} \) is isomorphic to \( \mathfrak{g} \), \( \mathfrak{y}^{(j)} \) is isomorphic to \( \mathfrak{u} \), \( \mathfrak{s}^{(t)} \) is isomorphic to \( \mathfrak{s} \) for all \( i \in I, j \in J, t \in T \) and \( \mathfrak{E} \) is a trivial \( \mathfrak{g} \)-module. As before, collecting the isomorphic \( \mathfrak{g} \)-submodules, we may assume

\[
\mathcal{L} = (\mathfrak{g} \otimes \mathfrak{A}) \oplus (\mathfrak{s} \otimes \mathfrak{B}) \oplus (\mathfrak{u} \otimes \mathfrak{C}) \oplus \mathfrak{E},
\]

in which \( \mathfrak{A}, \mathfrak{B}, \mathfrak{C} \) are vector superspaces. We recall (3.3) and use Proposition 1.8 to get that

\[
\mathfrak{G} := \sum_{\alpha \in R^{m,n} \setminus \{0\}} \mathfrak{g}^\alpha \oplus \sum_{\alpha \in R^{m,n} \setminus \{0\}} [\mathfrak{g}^\alpha, \mathfrak{g}^{-\alpha}]
\]

is a subsuperalgebra of \( \mathfrak{g} \) isomorphic to \( \text{osp}(m, n) \) with Cartan subalgebra

\[
\mathcal{H} = \sum_{\alpha \in R^{m,n} \setminus \{0\}} [\mathfrak{g}^\alpha, \mathfrak{g}^{-\alpha}]
\]

and root system \( R^{m,n} \). Consider (3.3) and set

\[
\mathcal{L} := \sum_{\alpha \in \Phi \setminus \{0\}} \mathcal{L}^\alpha \oplus \sum_{\alpha \in \Phi \setminus \{0\}} [\mathcal{L}^\alpha, \mathcal{L}^{-\alpha}],
\]
It is easy to see that $\mathcal{L}$ has a weight space decomposition $\mathcal{L} = \sum_{\alpha \in \Phi} \mathcal{L}^\alpha$ with respect to $\mathcal{H}$ with

$$\mathcal{L}^\alpha := \left\{ \sum_{\alpha \in \Phi \setminus \{0\}} [\mathcal{L}^\alpha, \mathcal{L}^{-\alpha}] \alpha \in \Phi \setminus \{0\}, \alpha = 0. \right\}$$

This in particular implies that

$$\mathcal{L}^\alpha = \sum_{i \in I} (\mathfrak{g}^{(i)})^\alpha + \sum_{j \in J} (\mathfrak{v}^{(j)})^\alpha + \sum_{t \in T} (\mathfrak{s}^{(t)})^\alpha \quad (\alpha \in \Phi \setminus \{0\}).$$

Moreover, setting

$$\Delta_1 := \text{span}_\mathbb{R} R^m \cap \Delta_a \quad \text{and} \quad \Delta_2 := \text{span}_\mathbb{R} R^m \cap \Delta_s,$$

and using Proposition 1.8 we have the following $\mathcal{G}$-modules

$$\mathcal{G}^{(i)} := \sum_{\alpha \in R^m \setminus \{0\}} (\mathfrak{g}^{(i)})^\alpha + \sum_{\alpha \in R^m \setminus \{0\}} [\mathfrak{g}, (\mathfrak{g}^{(i)})^{-\alpha}],$$

$$\mathcal{U}^{(j)} := \sum_{\alpha \in \Delta_1 \setminus \{0\}} (\mathfrak{v}^{(j)})^\alpha + \sum_{\alpha \in \Delta_1 \setminus \{0\}} [\mathfrak{g}, (\mathfrak{v}^{(j)})^{-\alpha}],$$

$$\mathcal{S}^{(t)} := \sum_{\alpha \in \Delta_2 \setminus \{0\}} (\mathfrak{s}^{(t)})^\alpha + \sum_{\alpha \in \Delta_2 \setminus \{0\}} [\mathfrak{g}, (\mathfrak{s}^{(t)})^{-\alpha}]$$

which are respectively isomorphic to $\mathcal{G}$, to the natural module $\mathcal{U}$ of $\mathcal{G}$ and to the second natural module $\mathcal{S}$ of $\mathcal{G}$. Also it is immediate that

1) $\mathcal{L}$ contains $\mathcal{G}$ as a subalgebra,
2) $\mathcal{L}$ is equipped with a weight space decomposition $\mathcal{L} = \bigoplus_{\alpha \in \Phi} \mathcal{L}^\alpha$, with respect to $\mathcal{H}$,
3) $\mathcal{L}^0 = \bigoplus_{\alpha \in \Phi \setminus \{0\}} \{[\mathcal{L}^\alpha, \mathcal{L}^{-\alpha}] \}

and so as above $\mathcal{L}$ is completely reducible with irreducible constituents isomorphic to $\mathcal{G}$, $\mathcal{U}$, $\mathcal{S}$ or to the trivial module. Since $\sum_{i \in I} \mathcal{G}^{(i)} \oplus \sum_{j \in J} \mathcal{U}^{(j)} \oplus \sum_{t \in T} \mathcal{S}^{(t)}$ is a $\mathcal{G}$-submodule of $\mathcal{L}$, there is a submodule $\mathcal{D}$ of $\mathcal{L}$ such that

$$\mathcal{L} = \sum_{i \in I} \mathcal{G}^{(i)} \oplus \sum_{j \in J} \mathcal{U}^{(j)} \oplus \sum_{t \in T} \mathcal{S}^{(t)} \oplus \mathcal{D}.$$ 

But for each nonzero $\alpha \in \Phi \setminus \{0\}$,

$$\mathcal{L}^\alpha = \sum_{i \in I} (\mathfrak{g}^{(i)})^\alpha \oplus \sum_{j \in J} (\mathfrak{v}^{(j)})^\alpha \oplus \sum_{t \in T} (\mathfrak{s}^{(t)})^\alpha \subseteq \sum_{i \in I} \mathcal{G}^{(i)} \oplus \sum_{j \in J} \mathcal{U}^{(j)} \oplus \sum_{t \in T} \mathcal{S}^{(t)}.$$

This means that $\mathcal{D}$ is a trivial $\mathcal{G}$-module. Now considering [33] and using the fact that vector spaces are flat, we may assume

$$\mathcal{L} = (\mathcal{G} \otimes \mathcal{A}) \oplus (\mathcal{S} \otimes \mathcal{B}) \oplus (\mathcal{U} \otimes \mathcal{C}) \oplus \mathcal{D},$$

in fact we identify $\mathcal{G} \otimes \mathcal{A}$, $\mathcal{S} \otimes \mathcal{B}$ and $\mathcal{U} \otimes \mathcal{C}$ with subspaces of $\mathfrak{g} \otimes \mathcal{A}$, $\mathfrak{s} \otimes \mathcal{B}$ and $\mathfrak{u} \otimes \mathcal{C}$ respectively. Now using the same argument as in [24] Lem. 3.6 and Pro. 3.10], $\mathcal{A} \oplus \mathcal{B} \oplus \mathcal{C}$ is equipped with a superalgebraic structure derived from the Lie superalgebraic structures on $\mathcal{L}$ and $\mathfrak{g}$,

$$\mathcal{L} = ((\mathfrak{g} \otimes \mathcal{A}) \oplus (\mathfrak{u} \otimes \mathcal{B}) \oplus (\mathfrak{s} \otimes \mathcal{C})) \oplus \mathcal{D},$$

and the stated properties in Theorem 3.4 hold.
3.2.3. Proof of Theorem 7.4. We recall that \( I_0 \subseteq I \) and \( J_0 \subseteq J \) are finite subsets with \( |I_0| = m \) and \( |J_0| = n \). Take \( \Lambda \) and \( \Gamma \) to be index sets with a symbol 0 belonging to \( \Lambda \cap \Gamma \) such that \( \{I_\lambda \mid \lambda \in \Lambda\} \) (resp. \( \{J_\gamma \mid \gamma \in \Gamma\} \)) is the set of finite subsets of \( I \) (resp. \( J \)) containing \( I_0 \) (resp. \( J_0 \)). For \((\lambda, \gamma) \in \Lambda \times \Gamma\), set

\[
\Psi^{\lambda,\gamma} := \Psi \cap \text{span}_\mathbb{Z}\{\epsilon_i, \delta_p \mid i \in I_\lambda, p \in J_\gamma\},
\]

\[
\Delta^{\lambda,\gamma}_1 := \Delta_\lambda \cap \text{span}_\mathbb{Z}\{\epsilon_i, \delta_p \mid i \in I_\lambda, p \in J_\gamma\},
\]

\[
R^{\lambda,\gamma} := R \cap \text{span}_\mathbb{Z}\{\epsilon_i, \delta_p \mid i \in I_\lambda, p \in J_\gamma\},
\]

and take

\[
\mathcal{L}^{\lambda,\gamma} := \sum_{a \in \Psi^{\lambda,\gamma}} \mathcal{L}^{\lambda,\gamma}_a + \sum_{a \in \Psi^{\lambda,\gamma}} [\mathcal{L}^{\lambda,\gamma}_a, \mathcal{L}^{\lambda,\gamma}_a],
\]

\[
u^{\lambda,\gamma} := \sum_{a \in \Delta^{\lambda,\gamma}_1} \nu^a + \sum_{a \in \Delta^{\lambda,\gamma}_1} \mathcal{L}^{\lambda,\gamma}_a u^a + \sum_{a \in \Delta^{\lambda,\gamma}_1} \mathcal{L}^{\lambda,\gamma}_a g^a u^{-a},
\]

\[
g^{\lambda,\gamma} := \sum_{a \in R^{\lambda,\gamma}} g^a + \sum_{a \in R^{\lambda,\gamma}} [g^a, g^{-a}],
\]

\[
\tilde{\theta}^{\lambda,\gamma} := \sum_{a \in \Delta^{\lambda,\gamma}_2} \tilde{\theta}^a + \sum_{a \in \Delta^{\lambda,\gamma}_2} \mathcal{L}^{\lambda,\gamma}_a \tilde{\theta}^a g^{-a}.\]

Using the result of Subsection 3.2.2, we find a subsuperalgebra \( D \) of \( \mathcal{L}^{0,0} \) and superspaces \( A, B \) and \( C \) such that the properties stated in Theorem 3.4 are satisfied and

\[
\mathcal{L}^{0,0} = (g^{0,0} \otimes A) \oplus (g^{0,0} \otimes B) \oplus (u^{0,0} \otimes C) \oplus D,
\]

moreover, for \( \lambda \in \Lambda \) and \( \gamma \in \Gamma \),

\[
\mathcal{L}^{\lambda,\gamma} = (g^{\lambda,\gamma} \otimes A) \oplus (g^{\lambda,\gamma} \otimes B) \oplus (u^{\lambda,\gamma} \otimes C) \oplus D.
\]

Now the result follows using the same argument as in [24, Thm. 4.1].

\[\square\]
