Visualization of HTLV-1–Specific Cytotoxic T Lymphocytes in the Spinal Cords of Patients With HTLV-1–Associated Myelopathy/Tropical Spastic Paraparesis

Eiji Matsuura, MD, PhD, Ryuji Kubota, MD, PhD, Yuetsu Tanaka, MD, PhD, Hiroshi Takashima, MD, PhD, and Shuji Izumo, MD, PhD

Abstract

Activated human T-lymphotropic virus type-1 (HTLV-1)–specific CD8-positive cytotoxic T lymphocytes (CTLs) are markedly increased in the periphery of patients with HTLV-1–associated myelopathy/tropical spastic paraparesis (HAM/TSP), an HTLV-1–induced inflammatory disease of the CNS. Although virus-specific CTLs play a pivotal role to eliminate virus-infected cells, the potential role of HTLV-1–specific CTLs in the pathogenesis of HAM/TSP remains unclear. To address this issue, we evaluated the infiltration of HTLV-1–specific CTLs and the expression of HTLV-1 proteins in the spinal cords of 3 patients with HAM/TSP. Confocal laser scanning microscopy with our unique staining procedure made it possible to visualize HTLV-1–specific CTLs infiltrating the CNS of the HAM/TSP patients. The frequency of HTLV-1–specific CTLs was more than 20% of CD8-positive cells infiltrating the CNS. In addition, HTLV-1 proteins were detected in CD4-positive infiltrating T lymphocytes but not CNS resident cells. Although neurons were generally preserved, apoptotic oligodendrocytes were frequently in contact with CD8-positive cells; this likely resulted in demyelination. These findings suggest that the immune responses of the CTLs against HTLV-1–infected CD4-positive lymphocytes migrating into the CNS resulted in bystander neural damage.

Key Words: Apoptosis, Cytotoxic T lymphocyte, Demyelination, HTLV-1–associated myelopathy/tropical spastic paraparesis (HAM/TSP), Human T-lymphotropic virus type-1 (HTLV-1).

INTRODUCTION

Human T-lymphotropic virus type 1 (HTLV-1) infection is estimated to affect 1 to 2 × 10^7 people worldwide. Although HTLV-1 infection is lifelong, the majority of infected individuals remain asymptomatic; only 1% to 2% of these individuals develop HTLV-1–associated diseases, including adult T-cell leukemia/lymphoma (1), and a range of chronic inflammatory diseases, including myelopathy (2–4), uveitis (5), arthritis (6), polymyositis (7, 8), inclusion-body myositis (9, 10), and alveolitis (11). The most recognized inflammatory disease is HTLV-1–associated myelopathy/tropical spastic paraparesis (HAM/TSP), in which CNS lesions correspond to progressive weakness of the lower extremities, with spasticity, urinary incontinence, and mild sensory disturbance. Patients with HAM/TSP exhibit higher HTLV-1 proviral load in the peripheral blood mononuclear cells (PBMCs) than asymptomatic HTLV-1 carriers (12). Furthermore, HTLV-1–infected cells accumulate in the cerebrospinal fluid (CSF) on neurologic exacerbation (13). One of the most striking features of the cellular immune response in patients with HAM/TSP is the highly elevated numbers of HTLV-1–specific CD8-positive cytotoxic T lymphocytes (CTLs) in PBMCs compared with asymptomatic HTLV-1 carriers (14, 15). These CTLs produce proinflammatory cytokines (16, 17). The HTLV-1–specific CTLs are thought to be a key factor in the pathogenesis of HAM/TSP (18, 19). This persistently activated CTL immune response to HTLV-1 provides unequivocal evidence of persistent HTLV-1 antigen expression in vivo. To date, no previous studies have shown CTLs and HTLV-1 proteins in CNS tissues from patients with HAM/TSP.

Although Skinner et al visualized antigen-specific T cells with nonfrozen tissues (20), the method has not been adapted to frozen tissue samples. In this study, we established novel in situ staining methods for detecting virus-specific CTLs and HTLV-1 proteins in frozen human tissue samples. We detected a number of HTLV-1–specific CTLs and HTLV-1–infected CD4-positive cells infiltrating the CNS and verified the bystander hypothesis that the interaction between HTLV-1–specific CTLs and HTLV-1–infected T lymphocytes causes damage to bystander neural cells in the CNS (21).

MATERIALS AND METHODS

Subjects

We obtained autopsied spinal cord tissue from 9 HAM/TSP patients after obtaining written informed consent from their...
family members and stored them at −80°C until use. Human T-lymphotropic virus type 1 Tax11-19 (LLFGYPVYV) and Tax301-309 (SFHSLHLLF) are well-characterized immunodominant epitopes that are restricted to HLA-A*02 and HLA-A*24, respectively (22, 23). Human leukocyte antigen (HLA) typing was performed in all of the autopsied samples (24). Three samples were found suitable for use in this study. The clinical characteristics of the patients are shown in Table 1. This study was approved by the Kagoshima University Ethics Committee.

**Immunohistochemistry**

Primary and secondary antibodies are listed in Table 2. Fresh-frozen spinal cord samples were cut into 8-μm-thick sections, placed on aminosilane-coated slides, and dried for 3 hours. After fixation with 4% paraformaldehyde (PFA) in PBS for 20 minutes at room temperature (RT), the sections were incubated with a primary monoclonal antibody (mAb) for 60 minutes at RT. The samples were washed with PBS after each step.

For immunohistochemistry, the sections were treated with 3% H2O2 in PBS for 20 minutes and subsequently incubated with horseradish peroxidase–labeled polymer-conjugated anti-mouse antibody (Ab) reagent (EnVision+ reagent; Dako, Tokyo, Japan) for 30 minutes at RT. Finally, peroxidase was visualized using 3-amino-9-ethylcarbazole (AEC) substrate as the red color. The sections were counterstained with hematoxylin and analyzed by light microscopy.

For immunofluorescence staining, the sections were incubated with fluorescence-conjugated secondary antibodies for 60 minutes at RT in the dark. The sections were counterstained with 4’,6-diamidino-2-phenylindole (DAPI) and analyzed using a confocal laser scanning microscope (FV500; Olympus, Tokyo, Japan). For double staining, 2 primary antibodies with different colors were used.

**TABLE 2. Primary and Secondary Antibodies Used for Immunohistochemical Studies**

| Antibody | Dilution | Company |
|----------|----------|---------|
| Mouse anti-CD4 mAb (4B12, IgG1) | 50 x | Dako, Tokyo, Japan |
| Rat anti-CD4 mAb (YNB46.1.8, IgG) | 50 x | Abcam, Tokyo, Japan |
| Mouse anti-CD3 mAb (UCHT1, IgG1) | 50 x | Beckman Coulter, Tokyo, Japan |
| Mouse anti-CD8 mAb (DK25, IgG1) | 50 x | Dako |
| Mouse anti-CD68 mAb (KP-1, IgG1) | 400 x | Dako |
| Mouse anti-HTLV-1 Tax mAb (L1-4, IgG3) | 250 x | Not applicable* |
| Mouse anti-HTLV-1 Gag mAb (TP-7, IgG1) | 400 x | Abcam |
| Mouse anti-HTLV-1 Env mAb (65/6C2, IgG1) | 2000 x | Abcam |
| Rabbit anti-Ki-67 Ab (IgG) | 100 x | Abcam |
| Mouse anti-granzyme B mAb (GB11, IgG1) | 50 x | Serotec, Kidlington, UK |
| Mouse anti-INF-γ mAb (45.15, IgG1) | 500 x | Ancell, Bayport, MN |
| Mouse anti-CNPase mAb (11-5B, IgG1) | 400 x | Millipore, Tokyo, Japan |
| Mouse anti-GFAP mAb (6 F2, IgG1) | 250 x | Dako |
| Mouse anti-perforin mAb (8G9, IgG2b) | 200 x | BioVision, Milpitas, CA |
| Rabbit anti-PE Ab | 500 x | BioGenesis, Westminster, CO |
| Rabbit anti-active caspase-3 mAb (E83-77, IgG) | 50 x | Epitomics, Burlingame, CA |
| Rabbit anti-single-stranded DNA (ss DNA) Ab (F7-26) | 50 x | Abcam |
| Alexa Fluor 488-, 594- or 647–conjugated goat anti-mouse IgG1 or IgG3 Abs | 1000 x | Invitrogen, Tokyo, Japan |
| Alexa Fluor 488–conjugated goat anti-rabbit IgG Ab | 1000 x | Invitrogen |
| Alexa Fluor 488–conjugated goat anti-rat IgG Ab | 1000 x | Invitrogen |

*Described in Lee et al (25).
Ab, antibody; CNPase, 2',3'-cyclic-nucleotide 3'-phosphodiesterase; GFAP, glial fibrillary acidic protein; HTLV-1, human T-lymphotropic virus-1; IFN-γ, interferon-γ; mAb, monoclonal antibody.
different immunoglobulin subclasses reacted to the sections simultaneously overnight at 4°C. The sections were incubated with 2 Alexa Fluor–conjugated secondary antibodies for relevant immunoglobulin subclasses. For multicolor staining, we always obtained images by sequentially scanning with each laser line to avoid the fluorescence bleeding. The sections were evaluated by 2 investigators.

In Situ Tetramer Staining

HTLV-1 Tax–specific T lymphocytes were detected with either phycoerythrin (PE)-labeled HLA-A*0201/Tax11-19-tetramer or HLA-A*2402/Tax301-309-tetramer (MBL, Japan) diluted to 1.0 μg/mL. HLA-A*0201/Tax11-19-pentamer was also used to corroborate the results of the tetramer in the staining of the CNS. Phycoerythrin-labeled HLA-A*0201/HIV Gag peptide (SLYNTVATL) tetramer or PE-labeled HLA-A*2402/HIV Env peptide (RYLKDQQLL) tetramer was used as an irrelevant control. The sections were fixed with PBS-buffered 0.1% PFA for 10 minutes and washed with PBS after each step. The sections were incubated with tetramer overnight at 4°C in the presence of protease inhibitors (Roche, Tokyo, Japan) and subsequently fixed again with PBS-buffered 4% PFA for 20 minutes at RT. Rabbit anti-PE Ab (500×; BioGenesis, Westminister, CO) was used as the secondary Ab and incubated with the sections for 60 minutes at RT. The signal was enhanced with the EnVision+ system and visualized with AEC chromogen. For immunofluorescence staining, the sections were incubated with goat anti-rabbit Ab labeled with Alexa Fluor 488 for 60 minutes at RT. For double staining, sections were simultaneously incubated with any of anti-CD8 mAb, anti–granzyme B mAb, anti–interferon-γ (IFN-γ) mAb, or Lt-4 mAb and with Tax-tetramer. After overnight incubation and fixation, the sections were incubated with rabbit anti-PE Ab for 60 minutes. The sections were then incubated with Alexa Fluor 594–conjugated anti–mouse IgG1 or IgG3 Ab and Alexa Fluor 488–conjugated goat anti-rabbit IgG Ab for 60 minutes at RT. 4,6-Diamidino-2-phenylindole was used for counterstaining. To determine the frequency of Tax-tetramer–positive cells among the CD8-positive cells, we counted the cells under full-field observation (400×).

Detection of HTLV-1–Infected Cells in the Tissues

Fresh-frozen spinal cord sections were used to detect HTLV-1–proteins. The sections were dried and fixed with 4% PFA for 20 minutes at RT. Anti–HTLV-1 Tax mAb (Lt-4), anti–HTLV-1 Gag mAb (TP-7), or anti–HTLV-1 Env mAb (65/6C2) was applied to the sections in combination with anti-CD3 mAb, anti-CD4 mAb, or anti–Ki-67 Ab. After the sections were incubated overnight at 4°C, they were incubated with isotype-specific secondary antibodies for 60 minutes at RT in the dark and subsequently counterstained with DAPI.

Detection of Apoptotic Cells

Apoptotic cells were detected with anti–active caspase-3 Ab or anti–single-stranded DNA Ab by light microscopy and confocal laser scanning microscopy. The cells were also detected with TdT-mediated dUTP nick end labeling method according to the manufacturer’s instructions (ApopTag Millipore, Billerica, MA).

RESULTS

General Findings in the CNS of HAM/TSP Patients

Transverse sections of the spinal cords of HAM/TSP patients demonstrated atrophy in the lateral columns with thickened meninges (Fig. 1A–C). Symmetric patchy myelin pallor in Luxol fast blue staining was observed in the affected long tracts, lateral cerebrospinal fasciculus, ventral and dorsal spino cerebellar fasciculi, spinotothalamic fasciculus in the lateral column, and fasciculus gracilis in the posterior columns. The essential histopathologic feature was a chronic progressive inflammatory process with marked parenchymal edema of lymphocytes and macrophages around the vessels (i.e. postcapillary venules) in both the gray and white matter of the spinal cord (Fig. 1D, E). The degree of cellular infiltration was strong in Patients 6315 and 8624, whereas Patient 6664 had no significant cell infiltrates (Table 1). Neurons in the anterior horns were generally preserved (Fig. 1F). Immunohistochemical staining of the spinal cord revealed remarkable infiltration of CD8-positive cells (Fig. 1G, H) and CD4-positive cells (Fig. 1I) and macrophages (data not shown) throughout the parenchyma, especially in perivascular areas. These histochemical findings are consistent with previous reports.

Detection of HTLV-1 Tax–Specific CTLs in the CNS

To validate the in situ tetramer staining procedure for visualization of HTLV-1–specific CTLs, PBMCs of HLA-A*02–positive patients with HAM/TSP were fixed on slides and stained with HLA-A*02/Tax11-19 tetramer and anti-CD8 mAb. The fluorescence pattern of the tetramer exactly colocalized with that of anti-CD8 mAb on the PBMCs (Fig. 2A). This is consistent with the fact that CD8 cells express a T-cell

FIGURE 1. Routine and histochemical study of spinal cords from patients with HTLV-1–associated myelopathy/tropical spastic paraparesis (HAM/TSP) by light microscopy. (A–C) The spinal cord (A, cervical level; B, lower thoracic level; C, lumbar level) of a HAM/TSP patient shows marked atrophy in the lateral columns; original magnification is 40×. The bars indicate 3 mm. (A) Symmetric myelin pallor is noted in the lateral cerebrospinal fasciculus, ventral and dorsal spino cerebellar fasciculi, lateral spinotothalamic fasciculus in the lateral column (arrowhead), anterior spinotothalamic fasciculus in the anterior column (thick arrow), and fasciculus gracilis in the posterior column (thin arrow). (B) There is marked atrophy, particularly of the lateral column. (C) Mild atrophy in the lumbar level. (D) A number of infiltrating cells are scattered throughout the section of the spinal cord. (E) Perivascular and parenchymal mononuclear cell infiltrates. (F) Neurons in the anterior horn are fairly preserved in the atrophied spinal cord. (G, H) Immunohistochemical study revealed that markedly infiltrating CD8-positive cells (red) are scattered in the parenchyma and around a small vessel in the spinal cord. (I) CD4-positive cells (red) are observed around a small vessel in the spinal cord. Nuclei were counterstained with hematoxylin (D-I, blue). Scale bar = 100 μm. (A–C) Luxol fast blue; (D–F) hematoxylin and eosin; (G–I) immunohistochemistry with hematoxylin counterstain.
We could not detect HTLV-1–specific CTLs at all with Tax-tetramer or -pentamer in frozen samples using a reported procedure for nonfrozen samples (20). We tested several modified staining procedures and finally found that prefixing the frozen sections at a very low concentration of PFA was optimal. We selected the sections that stained best with the tetramer or pentamer from several sections from each block. We detected HTLV-1 Tax11-19–specific CTLs in the parenchyma of the spinal cords from an HLA-A*02–positive patient (Fig. 2B) and an HLA-A*24–positive patient (Fig. 2C) with HLA-A*02/Tax-tetramer and HLA-A*24/Tax-tetramer, respectively. The CTLs were also detected in the thickened leptomeninges (Fig. 2D). On the other hand, no cells were detected by HIV Gag-tetramer and influenza-tetramer as tetramer controls (Fig. 2E).

**Accumulation of HTLV-1 Tax–Specific CD8-positive CTLs in the CNS**

To determine the frequency of HTLV-1 Tax–specific CTLs in CD8-positive lymphocytes infiltrating the CNS, we performed double staining for HTLV-1 Tax–specific CTLs and CD8-positive lymphocytes. Tax-specific CTLs stained with Tax-tetramer were frequently noted in the lesions. Double staining revealed that the fluorescence of Tax-tetramer colocalized with that of anti-CD8 mAb in all 3 patients (Fig. 3A–C). Meanwhile, HIV-tetramer restricted by either HLA-A*02 or HLA-A*24 did not bind any CD8-positive cells in the corresponding specimen (Fig. 3D). Next, we evaluated the frequency of Tax-specific CTLs in CD8-positive lymphocytes in 4 sections of the spinal cord from each patient. The percentages of Tax-specific CTLs in CD8-positive cells were 22.1% (62 of 280) and 31.1% (96 of 309) in patients with HLA-A*02–positive and HLA-A*24–positive patients, respectively (Table 3). Patient 6664 had no significant cellular infiltrates, and we only detected 2 HLA-A*24/Tax-tetramer–positive and no HLA-A*02/Tax-tetramer–positive cells in the 4 sections of the spinal cord from that patient. In addition to Tax-tetramer, Tax-pentamer was also used for the staining of the tissues from Patient 8624 to corroborate our results with Tax-tetramer. Similarly, the fluorescence of Tax-pentamer exactly colocalized with that of anti-CD8 mAb; the frequency of Tax-pentamer–positive cells in CD8-positive cells was 31% in the lesion (Fig. 3E).

**Detection of HTLV-1 Proteins in the CNS**

Although the HTLV-1 gene has been detected in CD4-positive lymphocytes, its viral protein has not been detected in freshly isolated lymphocytes. Therefore, we used HTLV-1–infected cell lines in a preliminary study for visualizing HTLV-1 Tax protein. Detected HTLV-1 Tax showed a patchy staining pattern in the nuclei of a human cell line (Figure, Supplemental Digital Content 1, parts A and B, http://links.lww.com/NEN/A676). Although HTLV-1 Tax was not detected in noncultured PBMCs, we detected the protein in PBMCs of patients with HAM/TSP after 8-hour culture (Figure, Supplemental Digital Content 1, part C, http://links.lww.com/NEN/A676).

We next detected 3 HTLV-1 proteins (Tax, Env, and Gag) in the CNS tissues of the HAM-TSP patients. Tax was found in the cells near vessels (Fig. 4A, B) and in the leptomeninges. The nuclear protein Tax showed a patchy staining pattern in the nuclei (Fig. 4C, D, G), whereas Env and Gag were detected in the cell membrane or cytoplasm (Fig. 4E–G). Double staining revealed that the cells expressing Tax, Env, or Gag were CD4-positive lymphocytes (Fig. 4C–F). CD68−, CD8−, CNPase−, and glial fibrillary acidic protein (GFAP)–positive cells were not positive for HTLV-1 Tax (Figure, Supplemental Digital Content 2, http://links.lww.com/NEN/A677). To investigate whether HTLV-1–infected cells proliferate in the CNS, we stained with anti-Tax mAb and anti-Ki-67 Ab (a marker of cell proliferation); however, Ki-67–positive Tax-positive cells were very rare; we detected only 2 cells in the 2 sections (data not shown). To investigate the frequency of HTLV-1–infected cells in the CD4-positive population and the frequency of apoptotic cells in HTLV-1–infected cells, we performed triple staining for CD4, active caspase-3, and HTLV-1 Env protein. The HTLV-1–positive cells in infiltrating CD4-positive cells were 60.3% and 82.4% in Patients 8624 and 6315, respectively (Table 3). More than 50% of infiltrating CD4-positive cells were infected with HTLV-1. Furthermore, HTLV-1–infected cells had a greater tendency to undergo apoptosis than noninfected cells; 36.4% of the infected cells were undergoing apoptosis, whereas 10.3% of noninfected cells were undergoing apoptosis in Patient 8624 (Table 3). Because the sample from Patient 6664 showed only a few cellular infiltrates, we could not evaluate the frequency of apoptosis in that case.

**Functional Molecules of HTLV-1–Specific CD8-Positive CTLs**

To investigate whether HTLV-1 Tax–specific CD8-positive CTLs have the ability to attack HTLV-1–infected CD4-positive cells in the CNS, we attempted to detect functional molecules of CTLs in the CNS. Granzyme B−, perforin−, and IFN-γ−positive cells were detected in both parenchymal and perivascular areas (Fig. 5A–C). Some of the cells stained with Tax-tetramer were positive for granzyme B (Fig. 5D). Furthermore, double staining revealed that CD8-positive cells sometimes were in contact with HTLV-1–infected cells (Fig. 5E), and that some HTLV-1 Tax–specific CTLs were next to HTLV-1–infected cells in the parenchyma (Fig. 5F). Human T-lymphotropic virus type-1 Tax–specific CTLs were not positive for Ki-67 (data not shown).

**Apoptotic Cells**

Next, we determined which cells underwent apoptosis in the CNS of the patients. Active caspase-3–positive cells (apoptotic cells) were frequently observed near CD8-positive cells in the parenchyma of the spinal cord, and some of them were in contact with CD8-positive cells (Fig. 5G–I). Active caspase-3 showed granular staining patterns in our pictures, although it has shown a diffuse cytoplasmic pattern in previous studies. The staining pattern may differ because of the different conditions of the frozen samples. We tried to detect the apoptotic cells with formalin-fixed paraffin-embedded samples by light microscopy. Caspase-3 was detected in the cell cytoplasm in those samples (Fig. 6A). Next, we stained the sections by methods other than the anti–active caspase-3 Ab to corroborate...
the frequent apoptosis in the spinal cord. Using a TdT-mediated dUTP nick end labeling assay, we detected a number of apoptotic cells (Fig. 6B, C). We also stained these spinal cord samples with anti-single-stranded DNA Ab and obtained similar findings (Fig. 6E). Altogether, the 3 staining methods showed frequent apoptosis in the affected spinal cords (Fig. 6).

Double staining revealed that apoptotic cells were CD4-positive or CD68-positive cells (Fig. 7D, E). Interestingly,
oligodendrocytes, which were stained with anti-CNPase mAb (Fig. 7B), were frequently undergoing apoptosis (Fig. 7F). This finding is consistent with the occurrence of demyelination in the spinal cords of HAM/TSP patients. However, oligodendrocytes were not stained with anti-HTLV-1 Tax mAb (data not shown) or anti-HLA-ABC Ab (Fig. 7G). Astrocytes that were stained with anti-GFAP mAb were diffusely distributed throughout the parenchyma (Fig. 7A), whereas GFAP-positive cells
were not positive for active caspase-3 (Fig. 7H). Neurons identified by their size as well as several particles within the neuronal body induced strong autofluorescence but were not positive for active caspase-3 (data not shown).

**DISCUSSION**

One of the most striking features of the cellular immune responses in patients with HAM/TSP is the highly increased numbers of HTLV-1–specific CTLs in PBMCs and CSF (14, 15); however, little is known about CTLs in the CNS. The fixation of human CNS samples with a very low concentration of PFA made it possible to visualize antigen-specific CTLs using tetramers or a pentamer in the CNS. Strikingly, their frequency reached more than 20% in CD8-positive cells that had migrated to the CNS. In a flow cytometric study in our cohort, we detected HTLV-1 Tax11–19–specific and HTLV-1 Tax301–309–specific CTLs in PBMCs from patients with HAM/TSP at 2.25% (0.0%–18.7%) (26) and 4.34% (0.2%–17.6%) (unpublished data), respectively. The present data are consistent with another report in which the frequency of HTLV-1 Tax–specific CTLs was higher in CSF than in PBMCs (18). Although the frequency of the CTLs differs by the case, it may be attributed to the difference in the phase of the disease or the duration of the illness.

Granzyme B and perforin, both known as cytotoxic molecules of CTLs, were detected along with IFN-γ in the parenchyma near the vessels in the CNS. Some CTLs contained granzyme B. Human T-lymphotropic virus type-1–specific CTLs were in contact with HTLV-1–infected cells, and apoptotic cells were frequently noted near the CD8-positive cells. These results strongly suggest that the infiltrating CTLs function as effector cells in the CNS. Interestingly, a considerable number of oligodendrocytes underwent apoptosis in the affected lesions. Meanwhile, the oligodendrocytes neither increase the expression levels of HLA-ABC nor express HTLV-1 proteins. The HTLV-1–positive cells were only infiltrating CD4-positive T cells. These results suggest that HTLV-1–infected CD4-positive T cells, but not oligodendrocytes, are the main targets of HTLV-1–specific CTLs in the CNS, and that an interaction between these infected CD4-positive cells and CTLs may cause bystander damage in oligodendrocytes that is associated with demyelination. Similarly, in a previous study on an animal model of neurotropic mouse coronavirus infection, activated CD8-positive T cells specific to neither the virus nor CNS antigens caused demyelination (27). Mechanisms of demyelination in other viral infections in the CNS, even those exhibiting dense infiltration of activated CTLs such as measles or lymphocytic choriomeningitis virus encephalitis, are unclear. Whereas a CD8-positive CTL has been considered to be beneficial for the host infected by a certain virus by diminishing virus-infected cells, recent studies clearly show that strong CTL responses to a pathogen sometimes induce an immunopathology that is harmful to the host. For example, in a mouse model of CNS lymphocytic choriomeningitis virus infection, the depletion of CD8-positive T cells rescues the animal from a fatal condition (28). In another report, highly activated CD8-positive T cells in the brain were correlated with early CNS dysfunction in simian immunodeficiency virus infection (29). Similarly, markedly increased HTLV-1–specific CTLs in the CNS may induce the development of HAM/TSP.

*Previous studies reported that the HTLV-1 antigen is hardly detected in PBMCs (30, 31), despite a high proviral...*
We also failed to detect any HTLV-1 proteins by the immunohistochemical or flow cytometric study in PBMCs from 20 HAM/TSP patients, even though the proteins became detectable after short-term culturing (Figure, Supplemental Digital Content 1, part C, http://links.lww.com/NEN/A676). Although the evidence of both vigorous persistent CTLs immune responses and increased IgM antibody specific for HTLV-1 in the peripheral blood of HAM/TSP patients have suggested that
FIGURE 5. Cytotoxic T-lymphocyte (CTL) molecules in the CNS. (A–C) Immunohistochemistry shows granzyme B (GzB)–positive cells (A), perforin-positive cells (B), and interferon-γ (IFN-γ)–positive cells (C) in the perivascular area of the spinal cord of Patient 8624. Black bars indicate 100 μm. (D) Double staining with HLA-A*2402/Tax301-309-tetramer (green) and anti-granzyme B monoclonal antibody (mAb) (red) reveals a GzB-positive HTLV-1–specific CTL in the parenchyma of the spinal cord (Patient 6315). (E) A cell expressing HTLV-1 Tax protein is in contact with a CD8-positive cell in the spinal cord of Patient 6315. (F) An HTLV-1 Tax–specific CTL is next to the cell expressing Tax protein in the spinal cord of Patient 8614. (G–I) Double staining for active caspase-3 (Cas3) (green) and CD8 (red, arrows in [H] and [I]) reveals CD8-positive cells in contact with active caspase-3–positive cells in the spinal cord of Patient 8624. Nuclei were counterstained with DAPI. White bars indicate 10 μm.
HTLV-1–infected cells could express viral antigens anywhere in the body of the infected individuals (14, 32), the expression of HTLV-1 proteins in vivo has remained elusive so far.

In this study, we succeeded in detecting HTLV-1 proteins in the CD4-positive T cells infiltrating the CNS. This is consistent with our previous reports in which HTLV-1–infected cells were determined to be CD4-positive lymphocytes in the CNS by in situ hybridization for HTLV-1 mRNA and in situ polymerase chain reaction for HTLV-1 DNA (33, 34). The infiltrating HTLV-1–infected CD4-positive cells may easily express the viral antigens in the CNS, which in turn facilitates the accumulation of HTLV-1–specific CTLs.

Human T-lymphotropic virus type-1 infection causes several organ-specific inflammatory diseases including HAM/TSP (2, 3). Previous reports demonstrating that HTLV-1 proviral loads are high in affected organs such as the muscles, lungs, and CNS suggest that HTLV-1–infected cells accumulate in the organs (13, 35). The pathogenesis model in which both

**FIGURE 6.** Detection of apoptotic cells in the CNS. (A) Some small cells are apoptotic (DAB; brown, arrowheads) detected by anti-active caspase-3 antibody (Ab). (B–D) TdT-mediated dUTP nick end labeling assay. (B) A number of apoptotic cells (DAB; brown) are detected in the spinal cord of a patient with HTLV-1–associated myelopathy/tropical spastic paraparesis (Patient 8624). (C) Some infiltrating small cells around a small vessel (arrowhead) and some relatively large cells in the parenchyma (arrow) are apoptotic. (D) The apoptotic cells are barely detectable in the control spinal cord from an HTLV-1–seronegative patient with hepatoma. (E, F) Anti-single-stranded DNA antibody staining. (E) Numerous apoptotic cells (AEC; red) are detected in the spinal cord (Patient 8624). A higher magnification picture in the inset shows apoptotic cells. (F) Apoptotic cells are barely detectable in the control patient spinal cord. Scale bar = 100 μm.
HTLV-1–infected CD4-positive T cells and the virus-specific CD8-positive CTLs infiltrate the organs from the peripheral blood followed by bystander tissue damage may explain why HTLV-1 infection can cause several chronic inflammatory diseases in various organs. Further studies are needed to determine whether the similar immunopathologic model can be applied to HTLV-1–associated inflammatory diseases in other organs.

**FIGURE 7.** Cell identification of apoptotic cells. (A–C) Astrocytes (A), oligodendrocytes (B), and apoptotic cells (C) were stained with anti–glial fibrillary acidic protein (GFAP) antibody (Ab), anti–2',3'-cyclic-nucleotide 3'-phosphodiesterase (CNPase) monoclonal antibody (mAb), or anti–active caspase-3 Ab, respectively, in the spinal cord of Patient 8624. Nuclei were counterstained with hematoxylin. (D–F, H) Double staining revealed that a CD4-positive cell (red, D), a CD68-positive cell (red, E), and some oligodendrocytes (red, F), but no astrocytes (red, H), were apoptotic (green) (arrowheads) in the spinal cord of Patient 8624. (G) Double staining with anti-CNPase mAb (green) and anti–HLA-ABC mAb (red) revealed that no oligodendrocyte expresses HLA-ABC. There is no double-positive signal (yellow) in the merged image. White bars indicate 20 μm. Cas3, active caspase-3.
