Abstract

As pre-trained language models have gotten larger, there has been growing interest in parameter-efficient methods to apply these models to downstream tasks. Building on the PROMPTUNING approach of Lester et al. (2021), which learns task-specific soft prompts to condition a frozen language model to perform downstream tasks, we propose a novel prompt-based transfer learning approach called SPoT: Soft Prompt Transfer. SPoT first learns a prompt on one or more source tasks and then uses it to initialize the prompt for a target task. We show that SPoT significantly boosts the performance of PROMPTUNING across many tasks. More importantly, SPoT either matches or outperforms MODELUNING, which fine-tunes the entire model on each individual task, across all model sizes while being more parameter-efficient (up to 27,000× fewer task-specific parameters). We further conduct a large-scale study on task transferability with 26 NLP tasks and 160 combinations of source-target tasks, and demonstrate that tasks can often benefit each other via prompt transfer. Finally, we propose a simple yet efficient retrieval approach that interprets task prompts as task embeddings to identify the similarity between tasks and predict the most transferable source tasks for a given novel target task.

1 Introduction

The past few years have seen the rapid development of ever larger pre-trained language models, where it has repeatedly been shown that scaling up the model size is a key ingredient for achieving the best performance (Devlin et al., 2019; Raffel et al., 2020; Brown et al., 2020). While this trend has continued to push the boundaries of possibility across various NLP benchmarks, the sheer size of these models presents a major challenge for their practical application. For 100B+ parameter models, fine-tuning and deploying a separate instance of the model for each downstream task would be prohibitively expensive.

To get around the infeasibility of fine-tuning, Brown et al. (2020) propose PROMPTDESIGN, where every downstream task is cast as a language modeling task and the frozen pre-trained model performs different tasks by conditioning on manual text prompts provided at inference time. Brown et al. (2020) demonstrate impressive few-shot performance with a single frozen GPT-3 model, although its performance depends highly on the choice of the prompt (Zhao et al., 2021) and still lags far behind state-of-the-art fine-tuning results.

More recent work has explored methods for learning soft prompts (Liu et al., 2021b; Qin and Eisner, 2021; Li and Liang, 2021; Lester et al., 2021), which can be seen as additional learnable parameters injected into the language model. Lester...
et al. (2021) propose PromptTuning, a simple method that learns a small task-specific prompt (a sequence of tunable tokens prepended to each example) for each downstream task during adaptation to condition the frozen language model to perform the task. Strikingly, as model capacity increases, PromptTuning becomes competitive with ModelTuning, which fine-tunes the entire model on each downstream task. Nevertheless, at small and moderate model sizes (less than 11B parameters), there are still large gaps between PromptTuning and ModelTuning.

In this paper, we propose SPoT: Soft Prompt Transfer, a novel transfer learning approach in the context of prompt tuning. SPoT first trains a prompt on one or more source tasks and then uses the resulting prompt to initialize the prompt for a target (downstream) task. Our experiments show that SPoT offers significant improvements over PromptTuning across tasks and model sizes. For instance, for the T5 Base (220M parameter) and T5 XXL (11B parameter) models (Raffel et al., 2020), we obtain a +10.1 and +2.4 point average accuracy improvement respectively on the SuperGLUE benchmark (Wang et al., 2019b). More importantly, SPoT performs competitively or significantly better than ModelTuning across all model sizes (see Figure 1).

Motivated by these results, we investigate transferability between tasks, through the lens of task prompts. Our goal is to answer the following questions: (a) For a given target task, when does initializing the prompt to that of a source task help improve performance?; (b) Can we use the task prompts to make more principled choices about which source tasks to use for a given novel target task? To answer (a), we conduct a systematic study of the T5 model using 26 NLP tasks and 160 combinations of source and target tasks. Our results indicate that tasks can often benefit each other via prompt transfer. To address (b), we interpret the learned task prompts as task embeddings to construct a semantic space of tasks and formalize the similarity between tasks. We design an efficient retrieval algorithm that measures task embedding similarity, allowing practitioners to identify source tasks that are likely to yield positive transferability for a given novel target task.

To summarize, our contributions are as follows:

• We propose SPoT, a novel prompt-based transfer learning approach, and show that scale is not necessary for PromptTuning to match the performance of ModelTuning. SPoT yields competitive or significantly better results than ModelTuning across all model sizes.

• We conduct a large-scale and systematic study on task transferability, which demonstrates conditions under which tasks can benefit each other via prompt transfer.

• We propose an efficient retrieval approach that interprets task prompts as task embeddings to construct a semantic space of tasks, and measures task embedding similarity to identify which tasks could benefit each other.

• To facilitate future work on prompt-based learning, we will release our library of task prompts and pre-trained models, and provide practical recommendations for adapting our library to NLP practitioners.

2 Improving PromptTuning with SPoT

To improve performance of PromptTuning, SPoT introduces source prompt tuning, an intermediate training stage between language model pre-training and target prompt tuning (Figure 2, left), to learn a prompt on one or more source tasks (while still keeping the base model frozen), which is then used to initialize the prompt for a target task. Our approach retains all the computational benefits of PromptTuning, i.e., for each target task, it only requires storing a small task-specific prompt while enabling the reuse of a single frozen pre-trained model for all tasks. In this section, we present a task-agnostic SPoT approach where a single transferred prompt is reused for all target tasks. In Section 3, we explore a task-specific approach that retrieves different prompts for different target tasks.

2.1 Experimental setup

Our frozen models are built on top of the pre-trained T5 checkpoints of all sizes: Small, Base, Large, XL, XXL with 60M, 220M, 770M, 3B, and 11B parameters, respectively. In our experiments with SPoT, we leverage the LM adapted version of T5\(^1\), which was found to be easier to optimize for PromptTuning (Lester et al., 2021).

\(^1\)T5 1.1 checkpoints trained for an additional 100K steps using the “prefix LM” objective (Raffel et al., 2020), available at https://github.com/google-research/text-to-text-transfer-transformer/blob/main/released_checkpoints.md
We study downstream performance on a diverse set of tasks from the GLUE (Wang et al., 2019c) and SuperGLUE (Wang et al., 2019b) benchmarks (each with 8 datasets). Due to restricted test set access for GLUE and SuperGLUE, we train for a fixed number of steps and report results on the validation set associated with each dataset.\(^4\)

### 2.1.3 Data for source prompt tuning

As with language model pre-training, the choice of training data is crucial for successful prompt transfer. To investigate the impact of source training data on downstream performance, we compare a diverse set of source tasks.

**A single unsupervised learning task:** We first consider training a prompt on a fraction of the C4 (Colossal Clean Crawled Corpus) dataset (Raffel et al., 2020) using the “prefix LM” objective discussed in Raffel et al. (2020). Although this task was used to pre-train our frozen T5 models already, it could still be helpful for learning a general-purpose prompt.

**A single supervised learning task:** Alternatively, we can train the prompt using a supervised task. We use either MNLI (Williams et al., 2018) or SQuAD (Rajpurkar et al., 2016) as single source tasks. MNLI was shown to be helpful for many sentence-level classification tasks (Phang et al., 2019), while SQuAD was found to generalize well to QA tasks (Talmor and Berant, 2019).

**A multi-task mixture:** So far, we have been training the prompt on a single source task. An alternative approach is multi-task training. Within T5’s unified text-to-text framework, this simply corresponds to mixing different datasets to improve training data access for GLUE and SuperGLUE, we train for a fixed number of steps and report results on the validation set associated with each dataset.\(^4\)

---

\(^3\)These datasets include grammatical acceptability judgments (CoLA (Warstadt et al., 2019)), sentiment analysis (SST-2 (Socher et al., 2013)), paraphrasing/semantic similarity (MRPC (Dolan and Brockett, 2005), STS-B (Cer et al., 2017), QQP (Iyer et al., 2017)), natural language inference (MNLI (Williams et al., 2018), QNLI (Wang et al., 2019c), RTE (Dagan et al., 2005, et seq.), CB (De Marneffe et al., 2019), coreference resolution (WSC (Levesque et al., 2012)), sentence completion (COPA (Roemmele et al., 2011)), word sense disambiguation (WIC (Pilehvar and Camacho-Collados, 2019)), and question answering (MultiRC (Khashabi et al., 2018), ReCoRD (Zhang et al., 2018), BoolQ (Clark et al., 2019)). We exclude the problematic WNLI (Levesque et al., 2012) dataset from GLUE, following Devlin et al. (2020).

\(^4\)For tasks with multiple metrics, we use an average of the metrics.
Together, we explore mixing datasets from different NLP benchmarks or families of tasks, including GLUE, SuperGLUE, natural language inference (NLI), paraphrasing/semantic similarity, sentiment analysis, question answering on MRQA (Fisch et al., 2019), commonsense reasoning on RAINBOW (Lourie et al., 2021), machine translation, summarization, and natural language generation on GEM (Gehrmann et al., 2021). We create a mixture of source tasks from each of the NLP benchmarks/families of tasks above, using the examples-proportional mixing strategy in Raffel et al. (2020) with an artificial dataset size limit \( K = 2^{19} \) training examples. Finally, we include a mixture of C4 and all the labeled datasets in the NLP benchmarks/families of tasks mentioned above (55 datasets).

### 2.1.4 Training details

For both source and target prompt tuning, we closely follow the training procedure in Lester et al. (2021). Specifically, for each target task, the only new parameters introduced during tuning are a shared prompt \( \rho \in \mathbb{R}^{L \times E} \) prepended to each (embedded) input sequence, where \( L, E \) are the prompt length and the embedding size, respectively. In all cases, we set \( L = 100 \) tokens. We tune the prompt with a batch size of 32 for a fixed number of steps \( S \). We use the Adafactor optimizer (Shazeer and Stern, 2018) with default parameters except with a constant learning rate of 0.3, weight decay of \( 1e-5 \), and parameter scaling turned off. The dropout probability is always kept at 0.1. All of our models are implemented using JAX (Bradbury et al., 2018) and Flax (Heek et al., 2020). During source prompt tuning, the prompt tokens are initialized using the \texttt{SAMPLED} scheme (where embeddings are sampled from the 5,000 most common tokens in T5’s vocabulary). During target prompt tuning, we initialize the prompts with the final prompt checkpoint from source prompt tuning. We save a checkpoint every 500 steps and report results on the checkpoint corresponding to the highest validation performance.

For \texttt{PROMPT} tuning, following Lester et al. (2021), we initialize the prompt using the \texttt{CLASS} scheme (where the prompt tokens are initialized with embeddings that represent an enumeration of the output classes) with a back off to the \texttt{SAMPLED} scheme to fill any remaining prompt positions. Training details for model tuning can be found in Appendix A.

**Longer tuning:** While the number of tuning steps \( S \) is set to 30K in Lester et al. (2021), we find that additional tuning is helpful when training on large datasets. As such, we set \( S \) to \( 2^{18} = 262,144 \), following Raffel et al. (2020), with the exception of ablation experiments (rows “— longer tuning”) in Table 1 which use \( S = 30K \).

### 2.2 Effect of \texttt{SPOT}

We compare the results of \texttt{SPOT} and other approaches in Figure 1 and Table 1. Below, we summarize and analyze each of our findings in detail.

text QT5 BASE with different prompt tuning approaches. We report the mean and standard deviation (in the subscript) across three random seeds. \texttt{SPOT} significantly improves performance and stability of \texttt{PROMPT} tuning across the two benchmarks.

Table 1: GLUE and SuperGLUE results achieved by applying T5 \texttt{BASE} with different prompt tuning approaches. We report the mean and standard deviation (in the subscript) across three random seeds. \texttt{SPOT} significantly improves performance and stability of \texttt{PROMPT} tuning across the two benchmarks.

| Method | GLUE | SuperGLUE |
|--------|-------|------------|
| **BASE** | | |
| **PROMPT TUNING** | 81.2\textsubscript{s} | 66.0\textsubscript{s} |
| — longer tuning | 78.4\textsubscript{t} | 63.1\textsubscript{t} |

| **SPOT with different source mixtures** | | |
| GLUE (8 tasks) | 82.8\textsubscript{s} | 73.2\textsubscript{s} |
| — longer tuning | 80.0\textsubscript{t} | 70.7\textsubscript{t} |

| GLUE (8 tasks) & 82.0\textsubscript{s} & 74.0\textsubscript{s} |
| C4 & 82.5\textsubscript{t} & 72.6\textsubscript{t} |
| MNLI & 82.5\textsubscript{t} & 72.6\textsubscript{t} |
| SQuAD & 83.2\textsubscript{t} & 74.0\textsubscript{t} |
| SuperGLUE (8 tasks) & 82.0\textsubscript{s}, & 66.8\textsubscript{s}, |
| NLI (7 tasks) & 82.6\textsubscript{t} & 71.4\textsubscript{t} |
| Paraphrasing/similarity (4 tasks) & 82.2\textsubscript{t} & 69.7\textsubscript{t} |
| Sentiment (5 tasks) & 81.1\textsubscript{t} & 68.6\textsubscript{t} |
| MRQA (6 tasks) & 81.8\textsubscript{t} & 68.4\textsubscript{t} |
| RAINBOW (6 tasks) & 80.3\textsubscript{t} & 64.0\textsubscript{t} |
| Translation (3 tasks) & 82.4\textsubscript{t} & 65.3\textsubscript{t} |
| Summarization (9 tasks) & 80.9\textsubscript{t} & 67.1\textsubscript{t} |
| GEM (8 tasks) & 81.9\textsubscript{t} & 70.5\textsubscript{t} |
| All (C4 + 55 supervised tasks) & 81.8\textsubscript{t} & 67.9\textsubscript{t} |
is complementary to prompt transfer. Additionally, when longer tuning is omitted, we observe that SPOT improves stability across runs.

**Different source mixtures can lead to performance gains:** Within our SPOT approach, we can compare the effectiveness of different source mixtures (see Table 1). Source prompt tuning on GLUE performs best on both GLUE and SuperGLUE, obtaining average scores of 82.8 and 73.2, respectively. Interestingly, unsupervised source prompt tuning on C4 (the same task used to pre-train our frozen models) still yields considerable improvements, even outperforming source prompt tuning on SuperGLUE for SuperGLUE tasks. Additionally, using MNLI or SQuAD as a single source dataset is particularly helpful for both GLUE and SuperGLUE. Finally, other source mixtures can also lead to significant gains, and some NLP benchmarks/families of tasks (e.g., NLIs and paraphrasing/semantic similarity) are more beneficial than others.

**SPOT helps close the gap with ModelTuning across all model sizes:** We compare the performance of different approaches across model sizes on SuperGLUE in Figure 1. For SPOT, we show the performance resulting from source prompt training on a mixture of GLUE tasks. As shown in Lester et al. (2021), ModelTuning becomes more competitive with scale, and at the XXL size (11B parameters), it even matches the performance of ModelTuning. However, at smaller model sizes, there are still large gaps between the two approaches. We show that SPOT helps close these gaps and even exceeds ModelTuning’s performance by a large margin at several model sizes, while retaining all the computational benefits conferred by ModelTuning. Finally, SPOT produces competitive performance to the strong Multi-TaskModelTuning baseline while being more parameter-efficient in both multi-task source tuning and target tuning; at the XXL size, SPOT achieves the best average score of 91.2, +1.1 points better than Multi-TaskModelTuning, despite having 27,000× fewer task-specific parameters.

### Table 2: Tasks used in our task transferability experiments, sorted by training dataset size.

| Name       | Task type       | Train |
|------------|----------------|-------|
| 16 source tasks |                 |       |
| C4         | language modeling | 365M  |
| DocNLI     | NLI             | 942K  |
| Yelp-2     | sentiment analysis | 560K  |
| MNLI       | NLI             | 393K  |
| QQP        | paraphrase detection | 364K  |
| QNL1       | NLI             | 105K  |
| ReCoRD     | QA              | 101K  |
| CxC        | semantic similarity | 88K   |
| SQuAD      | QA              | 88K   |
| DROP       | QA              | 77K   |
| SST-2      | sentiment analysis | 67K   |
| WinoGrande | commonsense reasoning | 40K  |
| HellaSWAG  | commonsense reasoning | 40K  |
| MultiRC    | QA              | 27K   |
| CosmosQA   | commonsense reasoning | 25K  |
| RACE       | QA              | 25K   |
| 10 target tasks |                 |       |
| BoolQ      | QA              | 9K    |
| CoLA       | grammatical acceptability | 9K    |
| STS-B      | semantic similarity | 6K    |
| WiC        | word sense disambiguation | 5K   |
| CR         | sentiment analysis | 4K    |
| MRPC       | paraphrase detection | 4K   |
| RTE        | NLI             | 2K    |
| WSC        | coreference resolution | 554  |
| COPA       | QA              | 400   |
| CB         | NLI             | 250   |

3 Investigating task transferability

Having established that prompt transfer is helpful for prompt tuning, we now shift our focus to investigating task transferability, through the lens of task prompts. To shed light on the transferability between different tasks, we conduct a large-scale empirical study with 26 NLP tasks (including one unsupervised task) and 160 combinations of source and target tasks. We demonstrate that tasks can help each other via prompt transfer in various situations, and task similarity plays an important role in determining transferability. Additionally, we show that by interpreting the task prompts as task embeddings, we can construct a semantic space of tasks and formulate a more rigorous notion of task similarity. Finally, we propose a retrieval algorithm that measures task embedding similarity to choose which source tasks to use for a given novel target task (Figure 2, right).

#### 3.1 Experimental setup

We study a diverse set of 16 source datasets and 10 target datasets (see Table 2). We consider all...
160 possible pairs of source and target datasets, and perform transfer from each source task to each target task.

### 3.1.1 Source and target tasks
The source tasks comprise one unsupervised task (C4) and 15 supervised tasks covering natural language inference (NLI), paraphrasing/semantic similarity, sentiment analysis, question answering (QA), and commonsense reasoning. All source tasks are data-rich or have been shown to yield positive transfer in prior work. To simulate a realistic scenario, we use low-resource tasks (less than 10K training examples) as target tasks. These tasks cover the above types of tasks, and additionally include grammatical acceptability, word sense disambiguation, and coreference resolution.

### 3.1.2 Training details
To limit computational costs, we use T5 base in all of our task transferability experiments. We perform 262,144 prompt tuning steps on each source task. The prompt checkpoint with the highest source task validation performance is selected to initialize prompts for different target tasks. Since the target datasets are small, we only perform 100K prompt tuning steps on each target task. We repeat each experiment three times with different random seeds. Other training details are the same as mentioned in Section 2.1.4.

### 3.1.3 Constructing a semantic space of tasks
Since only the prompt parameters are updated during prompt tuning on specific tasks, the task prompts likely encode task-specific knowledge. This suggests that they could be used to reason about the nature of tasks and their relationships. To test this idea, we interpret task prompts as task embeddings and construct a semantic space of tasks. Note that while we use the best prompt checkpoints from the source tasks for transfer to the target tasks, we use earlier prompt checkpoints as our task embeddings. This enables fast computation of task embeddings for novel target tasks. In our experiments, the task embedding is derived from a fixed prompt checkpoint, i.e., at 10K steps, for every task. We estimate the similarity between two tasks $t^1, t^2$ by measuring the similarity between their corresponding task embeddings $e^1, e^2$, using the following metrics:

\[ \text{Cosine Similarity of Average Tokens:} \quad \text{sim}(t^1, t^2) = \cos\left(\frac{1}{C} \sum_e e^1_i, \frac{1}{C} \sum_e e^2_i\right), \]

where $e^1_i, e^2_i$ denote the respective prompt tokens of $e^1, e^2$, and $\cos$ denotes the cosine similarity.

\[ \text{Per-Token Average Cosine Similarity:} \quad \text{sim}(t^1, t^2) = \frac{1}{C^2} \sum_i \sum_j \cos(e^1_i, e^2_j). \]

### 3.2 Predicting and exploiting transferability
We leverage our task embeddings to predict and exploit task transferability. Specifically, we explore methods to predict the most beneficial source tasks for a given target task and then make use of their prompts to improve performance on the target task. To enlarge our set of source prompts, we use the prompts from all the three different prompt tuning runs on each source task, resulting in 48 source prompts. Given a target task $t$ with task embedding $e^t$, we rank all the source prompts $\rho^s$ in descending order by the similarity between their corresponding task embeddings $e^s$ and the target embedding $e^t$:

\[ \text{sim}(e^s, e^t). \]

We denote the ranked list of source prompts as $\rho^s$, where $r$ denotes the rank ($r = 1, 2, \ldots, 48$). We experiment with the following methods:

**Best of Top-k:** We select the top-$k$ source prompts and use each of them individually to initialize the target prompt. This procedure requires prompt tuning $k$ times on the target task $t$, once for each source prompt. The best individual result is then used for evaluating the effectiveness of this method.

**Top-k Weighted Average:** We initialize the target prompt with a weighted average of the top-$k$ source prompts $\sum_{r=1}^{k} \alpha_r \rho^s$, so that we only perform prompt tuning on the target task $t$ once. The weights $\alpha_r$ are computed as $\alpha_r = \frac{\text{sim}(e^s_r, e^t)}{\sum_{r=1}^{k} \text{sim}(e^s_r, e^t)}$, where $e^s_r$ denotes the corresponding task embedding of $\rho^s$.

**Top-k Multi-task Mixture:** We first identify the source tasks whose prompts are in the top-$k$ prompts and mix their datasets and the target dataset together, using the examples-proportional mixing strategy of Raffel et al. (2020). Then, we
perform source prompt tuning on this multi-task mixture and use the final prompt checkpoint to initialize the prompt for target prompt tuning.

3.2.1 Evaluation

We report the average score across the target tasks achieved by using each of the methods described above. For each target task $t$, we measure the average and standard deviation of performance across the three different prompt tuning runs (which result in different task embeddings $e^t$). For comparison, we report the absolute and relative improvements over the baseline when prompt tuning on each target task from scratch (i.e., without any prompt transfer). Additionally, we include the oracle results achieved by using a brute-force search to identify the best possible out of 48 source prompts for each target task.

3.3 Effect of prompt-based task embeddings

In this section, we first analyze our task transferability results. Then, we demonstrate the effectiveness of using prompt-based task embeddings for representing tasks, and for predicting and exploiting task transferability.

Tasks can help each other via prompt transfer in various scenarios: The results of our task transferability experiments (see Table 4 in Appendix C) indicate that in many cases, transferring the prompt from a source task to a target task (SOURCE $\rightarrow$ TARGET) can provide significant gain on the target task. The transfer MNLI $\rightarrow$ CB yields the largest relative error reduction of 58.9% (from an average score of 92.7 to 97.0), followed by MNLI $\rightarrow$ COPA (29.1%) and ReCoRD $\rightarrow$ WSC (20.0%). Using the best source prompt (out of 48) for each target task dramatically improves the average score across 10 target tasks from 74.7 to 80.7. Overall, our results show effective transfer from large source tasks that involve high-level reasoning about semantic relationships among sentences (e.g., MNLI), or when the source and target tasks are similar (e.g., CxC $\rightarrow$ STS-B). Interestingly, positive transfer can occur in cases where the tasks are relatively dissimilar (e.g., ReCoRD $\rightarrow$ WSC, SQuAD $\rightarrow$ MRPC, CxC $\rightarrow$ WiC).

Task embeddings capture task relationships: Figure 3 shows a hierarchically-clustered heatmap of cosine similarities between the task embeddings of the 26 NLP tasks we study. Our prompt-based task embeddings capture task relationships: similar tasks are grouped together into clusters.

Figure 3: A clustered heatmap of cosine similarities between the task embeddings of the 26 NLP tasks we study. Our prompt-based task embeddings capture task relationships: similar tasks are grouped together into clusters.

![Figure 3](image)

Figure 4: Correlation between task similarity and task transferability. Each point represents a source prompt. Cosine similarity (x-axis) is between that source task embedding and the indicated target task’s embedding (orange title), averaged over three runs for the target task. Relative error reduction (y-axis) measures the improvement on the target task when performing prompt transfer from that source prompt. We include the Pearson correlation coefficient ($r$) and p-value.

![Figure 4](image)

Table 5 in Appendix C contains more cases.
are grouped together into clusters, including question answering (SQuAD, ReCoRD, and DROP; MultiRC and BoolQ), sentiment analysis (Yelp-2, SST-2, and CR), NLI (MNLI and CB; DocNLI and RTE), semantic similarity (STS-B and CxC), paraphrasing (MRPC and QQP), and commonsense reasoning (Winogrande, HellaSWAG, and CosmosQA). We note that QNLI, which is an NLI task built from the SQuAD dataset, is not closely linked to SQuAD; this suggests that our task embeddings are more sensitive to the type of task than domain similarity. Interestingly, they also capture the unintuitive case of ReCoRD’s high transferability to WSC. Additionally, task embeddings that are derived from different prompts of the same task have high similarity scores (see Appendix D).

Correlation between task embedding similarity and task transferability: Figure 4 shows how the relative error reduction on a target task changes as a function of the similarity between the source and target task embeddings. Overall, we find that there is a significantly positive correlation between task embedding similarity and task transferability on four (out of 10) target tasks we study, including STS-B ($p < 0.001$), CB ($p < 0.001$, not shown), WSC ($p < 0.01$), and RTE ($p < 0.05$), while it is less significant on the other tasks.

### Task embeddings can be used to predict and exploit task transferability

| Method | Change | Avg. score |
|-------|--------|------------|
| BASELINE | - | 74.707 |
| BRUTE-FORCE SEARCH ($k = 48$) | $6.0_{0.1}$ | $26.5_{1.1}$ | $80.7_{0.0}$ |
| COSINE SIMILARITY OF AVERAGE TOKENS | | |
| BEST of Top-$k$ | | |
| $k = 1$ | $1.5_{0.3}$ | $11.7_{1.1}$ | $76.2_{0.1}$ |
| $k = 3$ | $2.7_{0.6}$ | $16.6_{1.1}$ | $77.4_{0.3}$ |
| $k = 6$ | $3.8_{0.1}$ | $20.0_{0.1}$ | $78.5_{0.5}$ |
| $k = 9$ | $4.5_{0.1}$ | $22.2_{1.1}$ | $79.2_{0.1}$ |
| $k = 12$ | $5.0_{0.1}$ | $23.6_{2.2}$ | $79.4_{0.4}$ |
| $k = 15$ | $5.4_{0.1}$ | $24.9_{1.8}$ | $80.1_{0.5}$ |
| PER-TOKEN AVERAGE COSINE SIMILARITY | | |
| BEST of Top-$k$ | | |
| $k = 1$ | $2.0_{0.1}$ | $12.1_{1.1}$ | $76.7_{0.7}$ |
| $k = 3$ | $2.9_{0.1}$ | $17.0_{0.1}$ | $77.5_{0.4}$ |
| $k = 6$ | $4.5_{0.1}$ | $22.1_{1.2}$ | $79.2_{0.1}$ |
| $k = 9$ | $4.6_{0.1}$ | $22.6_{0.9}$ | $79.5_{0.2}$ |
| $k = 12$ | $5.0_{0.1}$ | $23.5_{1.4}$ | $79.6_{0.1}$ |
| $k = 15$ | $5.3_{0.1}$ | $24.5_{2.2}$ | $80.0_{0.4}$ |
| TOP-$k$ WEIGHTED AVERAGE | | |
| best $k = 3$ | $1.9_{0.3}$ | $11.5_{0.7}$ | $76.6_{0.1}$ |
| TOP-$k$ MULTI-TASK MIXTURE | | |
| best $k = 12$ | $3.1_{0.3}$ | $15.3_{0.8}$ | $77.8_{0.1}$ |

Table 3: Task embeddings provides an effective means of predicting and exploiting task transferability. Using BEST of Top-$k$ with $k = 3$ improves over the baseline by +2.8 points. With larger values of $k$ ($\leq 15$), we can retain most of the benefits conferred by prompt transfer. For TOP-$k$ WEIGHTED AVERAGE and TOP-$k$ MULTI-TASK MIXTURE, we experiment with different values of $k \in \{3, 6, 9, 12\}$ and report the best results.

Parameter-efficient transfer learning & language model prompting

Pre-trained language models have been shown to be an effective means for improving state-of-the-art results on many NLP benchmarks (Devlin et al., 2019; Liu et al., 2019b; Yang et al., 2019; Lan et al., 2020; Raffel et al., 2020; Brown et al., 2020; He et al., 2021). However, MODEL_TUNING (a.k.a fine-tuning)—the cur-
rent dominant approach for applying these models to downstream tasks—can become impractical, as fine-tuning all of the pre-trained parameters for each task can be prohibitively expensive, especially as model size continues to increase.

To address this issue, early work uses compression techniques, such as knowledge distillation (Sanh et al., 2019; Jiao et al., 2020; Sun et al., 2020) and model pruning (Fan et al., 2020; Sanh et al., 2020; Chen et al., 2020), to obtain lightweight pre-trained models. Other work involves updating only small parts of the language model (Zaken et al., 2021) or training task-specific modules, such as adapters (Houlsby et al., 2019; Karimi Mahabadi et al., 2021) and/or low-rank structures (Mahabadi et al., 2021; Hu et al., 2021), while keeping most or all of the pre-trained parameters fixed. Notably, Brown et al. (2020) demonstrate remarkable few-shot learning performance with a single frozen GPT-3 model using PROMPT DESIGN, where every task is cast as feeding the model a manual text prompt at inference time for context and asking it to produce some output text.

Several efforts have since focused on developing prompt-based learning approaches with carefully handcrafted prompts (Schick and Schütze, 2021), prompt mining and paraphrasing (Jiang et al., 2020b), gradient-based search for improved prompts (Shin et al., 2020), and automatic prompt generation (Gao et al., 2021). The use of hard prompts, however, was found to be sub-optimal and sensitive, i.e., there is no obvious correlation between downstream performance and the prompt format, and minor changes in the prompt can lead to significant differences in downstream performance (Liu et al., 2021b). As such, recent work has shifted toward learning soft prompts (Liu et al., 2021b; Qin and Eisner, 2021; Li and Liang, 2021; Lester et al., 2021), which can be seen as some additional learnable parameters injected into the language model. We refer readers to Liu et al. (2021a) for a recent survey on prompt-based learning research.

Concurrent work (Gu et al., 2021) also explores the effectiveness of prompt pre-training. Their approach uses hand-crafted pre-training tasks tailored to different types of downstream tasks, which limits its application to novel downstream tasks. In contrast, we use existing tasks as source tasks and show that prompt transfer can confer benefits even when there are mismatches (e.g., task type, input/output format) between the source and target tasks. Their work also focuses on the few-shot setting, whereas we work in context of larger datasets. Additionally, we study task transferability and demonstrate that tasks can often help each other via prompt transfer, and task prompts can be interpreted as task embeddings to formalize task similarity to identify which tasks could benefit each other.

**Task transferability**

We also build on existing work on task transferability in NLP (Phang et al., 2019; Wang et al., 2019a; Liu et al., 2019a; Talmor and Berant, 2019; Pruksachatkun et al., 2020; Vu et al., 2020; Poth et al., 2021) and computer vision (Zamir et al., 2018; Achille et al., 2019; Yan et al., 2020). Prior work shows effective transfer from data-rich source tasks (Phang et al., 2019), those that require complex reasoning and inference (Pruksachatkun et al., 2020), or those that are similar to the target task (Vu et al., 2020). There have also been efforts to predict transferability between tasks (Bingel and Søgaard, 2017; Vu et al., 2020; Poth et al., 2021). Vu et al. (2020) use task embeddings derived from either the input text or the diagonal Fisher information matrix of the language model, while Poth et al. (2021) explore adapter-based approaches. Here, our use of T5 allows us to better model the space of tasks, as every task is cast into a unified text-to-text format and the same model (without task-specific components) is used across tasks. Additionally, prompt-based task embeddings are comparatively cheaper to obtain.

**5 Conclusion**

In this paper, we study transfer learning in the context of prompt tuning. We show that scale is not necessary for PROMPT TUNING to match the performance of MODEL TUNING. Our SPOT approach matches or even exceeds the performance of MODEL TUNING by a large margin across model sizes while being more parameter-efficient (up to 27,000× fewer task-specific parameters). Our large-scale study on task transferability indicates that tasks can benefit each other via prompt transfer in various scenarios. Finally, we demonstrate that task prompts can be interpreted as task embeddings to formalize the similarity between tasks. We propose a simple yet efficient retrieval approach that measures task similarity to identify which source tasks could confer benefits to a novel target task. Taken as a whole, we hope that our work will spur more research into prompt-based transfer learning.
Acknowledgements

We thank Mohit Iyyer, Sebastian Ruder, Kalpesh Krishna, Thang Luong, Quoc Le, and the members of the Descartes team for helpful discussion and feedback. We would also like to thank Lucas Dixon, Grady Simon, and Slav Petrov for their comments on this manuscript. Finally, we are grateful to Vamsi Aribandi for his work on preprocessing several datasets used in our experiments.

Appendices

A Additional training details

For model tuning approaches, we use the default hyperparameters for T5 (Raffel et al., 2020), i.e., learning rate 0.001, Adafactor optimizer with pre-training parameter states restored, and dropout probability 0.1. To improve the model tuning baselines, we perform a sweep over the batch size hyperparameter and select $2^{16}$ tokens per batch, following Lester et al. (2021).

B Source datasets used in our SPOT experiments in Section 2

Figure 5 displays the datasets used in our PROMPT-TUNING with SPOT experiments in Section 2. In addition to the C4 unlabeled dataset (Raffel et al., 2020), we use 55 labeled datasets. These datasets come from common NLP benchmarks/families of tasks, namely:

- GLUE (Wang et al., 2019c), including CoLA (Warstadt et al., 2019), SST-2 (Socher et al., 2013), MRPC (Dolan and Brockett, 2005), QQP (Iyer et al., 2017), STS-B (Cer et al., 2017), MNLI (Williams et al., 2018), QNLI (Wang et al., 2019c), and RTE (Dagan et al., 2005, et seq.).

- SuperGLUE (Wang et al., 2019b), including BoolQ (Clark et al., 2019), CB (De Marneffe et al., 2019), COPA (Roemmele et al., 2011), MultiRC (Khashabi et al., 2018), ReCoRD (Zhang et al., 2018), RTE, WiC (Pilehvar and Camacho-Collados, 2019), and WSC (Levesque et al., 2012).

- Natural language inference (NLI), including ANLI (Nie et al., 2020), CB, DocNLI (Yin et al., 2021), MNLI, QNLI, RTE, and SNLI (Bowman et al., 2015).

- Paraphrasing/semantic similarity, including CxC (Parekh et al., 2021), MRPC, QQP, and STS-B.

- Sentiment analysis, including CR (Hu and Liu, 2004), Goemotions (Demszky et al., 2020), Sentiment140 (Go et al., 2009), SST-2, and Yelp-2 (Zhang et al., 2015).

- Question answering on MRQA (Fisch et al., 2019), including SQuAD (Rajpurkar et al., 2016), NewsQA (Trischler et al., 2017), TriviaQA (Joshi et al., 2017), SearchQA (Dunn et al., 2017), HotpotQA (Yang et al., 2018), and NaturalQuestions (NQ (Kwiatkowski et al., 2019)).

- Commonsense reasoning on RAINBOW (Lourie et al., 2021) including αNLI (Bhagavatula et al., 2020), CosmosQA (Huang et al., 2019), Hel-laSWAG (Zellers et al., 2019), PIQA (Bisk et al., 2020), SocialIQA (Sap et al., 2019), and WinoGrande (Sakaguchi et al., 2020).

- Machine translation, including WMT EnDe (Bojar et al., 2014), WMT EnFr (Bojar et al., 2015), and WMT EnRo (Bojar et al., 2016).

- Summarization, including Aeslc (Zhang and Tetreault, 2019), BillSum (Kornilova and Eidelman, 2019), CNN/Dailymail (Hermann et al., 2015; See et al., 2017), Wikilingua (Ladhak et al., 2020), Gigaword (Graff et al., 2003; Rush et al., 2015), MultiNews (Fabbri et al., 2019), Newsroom (Grusky et al., 2018), SAMSum (Gliwa et al., 2019), and XSum (Narayan et al., 2018).

- Natural language generation on GEM (Gehrmann et al., 2021), including CommonGen (Lin et al., 2020), DART (Nan et al., 2021), E2E (Duscek et al., 2019), SGD (Rastogi et al., 2020), WebNLG (Gardent et al., 2017), WikiAuto (Jiang et al., 2020a), XSum, and Wikilingua.

C Task transferability results

The full results of our task transferability experiments can be found in Table 4. We show that in many cases, initializing the prompt to that of a source task can provide significant gain on a target task. Table 5 displays positive transfers with more than 10% relative error reduction on the target task.

D Task embedding similarity

In Figure 6, we show a clustered heatmap of cosine similarities between the task embeddings of the 26 NLP tasks we study in our task transferability experiments. For each task, we include the resulting task embeddings from all the three different prompt tuning runs on the task. As can be seen, our task embeddings capture task relationships: similar tasks...
are grouped together into clusters. Additionally, task embeddings that are derived from different prompts of the same task are linked together.
Figure 5: Datasets used in our PROMPT Tuning with SPOT experiments in Section 2. C4, MNLI, and SQuAD were all used by themselves as single source tasks in addition to being mixed in with other tasks.

| GLUE | NLI | Paraphrasing/Similarity | RAINBOW | SuperGLUE | Sentiment | MRQA | GEM |
|------|-----|-------------------------|---------|-----------|-----------|------|-----|
| CoLA | ANLI | DocNLI | QQP | DocNLI | CR | C4 | ANLI  |
| STS-B | CB | RTE | QQP | QQP | Generator | SST-2 | CB |
| MRPC | RTE | MRPC | HELLESWAG | PIQA | RAINBOW | SocialQA | QQP |
| STS-B | NLI | RTE | cosNLI | OKWNQA | CxC | RAINBOW | PIQA |
| QNLI | SNLI | SNLI | QNLI | WSC | COPA | GEM | PIQA |
| WiC | WSC | COPA | MRPC | CxC | WSC | COPA | GEM |
| RACE | COPA | CxC | HELLESWAG | PIQA | COPA | GEM | PIQA |

Table 4: Tasks can benefit each other via their prompts. The orange-colored row shows the results of prompt tuning T5 BASE on the target tasks without any prompt transfer. Each cell in the other rows represents the target task performance when transferring the prompt from the associated source task (row) to the associated target task (column). Positive transfers are shown in green and the best results are highlighted in bold (green). Numbers in the subscript indicate the standard deviation across 3 random seeds.

| Baseline | CoLA | STS-B | CR | MRPC | RTE | BoolQ | WIC | WSC | COPA | CB |
|----------|------|-------|----|------|-----|-------|-----|-----|------|----|
|          | 52.9 | 88.1  | 93.5 | 86.1 | 68.7 | 73.0  | 63.6 | 71.5 | 56.7 | 92.7 |
