Hadronic production of top-squark pairs with electroweak NLO contributions

Wolfgang Hollik, Monika Kollár, and Maike K. Trenkel

Max-Planck-Institut für Physik, Föhringer Ring 6, D-80805 München, Germany

Abstract: Presented are complete next-to-leading order electroweak (NLO EW) corrections to top-squark pair production at the Large Hadron Collider (LHC) within the Minimal Supersymmetric Standard Model (MSSM). At this order, also effects from the interference of EW and QCD contributions have to be taken into account. Moreover, photon-induced top-squark production is considered as an additional partonic channel, which arises from the non-zero photon density in the proton.

1. Introduction

Within supersymmetric theories top-squarks are the supersymmetric partners of the left- and right-handed top quarks. The two superpartners \( \tilde{t}_L \) and \( \tilde{t}_R \), which belong to chiral supermultiplets \( \tilde{Q} \) and \( \tilde{T} \), in general mix to produce two mass eigenstates \( \tilde{t}_1 \) and \( \tilde{t}_2 \). In many supersymmetric models the lighter mass eigenstate appears as the lightest colored particle \( \tilde{t}_1 \), for reasons related to the large top Yukawa coupling. The large mixing in the stop sector leads to a substantial splitting between the two mass eigenstates, and the evolution from the GUT scale to the electroweak scale yields low values for the stop masses when a universal scalar mass is assumed at the high scale \( \tilde{M}_G \). The search for top-squarks is therefore of particular interest for the coming LHC experiments, where they would be primarily produced in pairs via the strong interaction, with relatively large cross sections.

Current experimental limits on top-squark pair production include searches performed at LEP \( [3] \) reviewed e.g in \( [4] \), and at the Tevatron, done by the CDF and DØ collaborations in approximately 90 pb\(^{-1}\) of Run I data \( [5] \). Extended searches have been done using Run II data samples by both CDF and DØ \( [6] \). Limits on the top-squark mass, depending on the
mass of the lightest neutralino, are provided with the assumption that $\text{BR}(\tilde{t}_1 \rightarrow c\chi^0_1) = 100\%$ in [7].

Experimental searches for the top-squarks have also been done in $ep$ collisions at HERA [8], where only single stop production could be kinematically accessed and hence constraints have been derived essentially on the R-parity violating class of supersymmetric models.

Concerning the theoretical predictions, QCD-based Born-level cross sections for the production of squarks and gluinos in hadron collisions have been calculated in [9]. They have been improved by including NLO corrections in supersymmetric QCD (SUSY-QCD), worked out in [10] with the restriction to final state squarks of the first two generations, and for the stop sector in [11]. The production of top-squark pairs in hadronic collisions is diagonal at lowest order at $O(\alpha_s^3)$. Electroweak (EW) contributions of $O(\alpha^2)$ are suppressed by two orders of magnitude. Also at $O(\alpha_s^3)$ the production mechanism is still diagonal. Non-diagonal production occurs at $O(\alpha_s^4)$, and the cross section is accordingly suppressed. Production of non-diagonal top-squark pairs can also proceed at $O(\alpha^2)$ mediated by $Z$-exchange through $q\bar{q}$ annihilation [12] as well as in $e^+e^-$ annihilation [13].

The LO cross section for diagonal top-squark pair production depends only on the mass of the produced squarks. As a consequence, bounds on the production cross section can easily be translated into lower bounds on the lightest stop mass. At NLO, the cross section becomes considerably changed and dependent on other supersymmetric parameters, like mixing angles, gluino mass, masses of other squarks, etc., which enter through the higher order terms. Once top-squarks are discovered, measurement of their masses and cross sections will provide important observables for testing and constraining the supersymmetric model.

In the following, we study the NLO contributions to diagonal top-squark pair production that arise from the electroweak interaction within the Minimal Supersymmetric Standard Model (MSSM). We assume the MSSM with real parameters, R-parity conservation, and minimal flavor violation. The outline of our paper is as follows. In Section 2, we present analytical expressions for the partonic and hadronic LO cross sections. We also introduce some basic notations used throughout the paper. Section 3 is dedicated to the classification of the NLO EW contributions into virtual and real corrections with the treatment of soft and collinear singularities, and photon-induced contributions. In Section 4, we give a list of input parameters and conventions, followed by our numerical results for the hadronic cross sections and distributions for $pp$ collisions at a center-of-mass energy $\sqrt{S} = 14$ TeV at the LHC. We also investigate the application of kinematical cuts, and we analyze the impact of varying the MSSM parameters.

2. Top-squark eigenstates and LO cross sections

In the MSSM Lagrangian, mixing of the left- and right-handed top-squark eigenstates $\tilde{t}_{L/R}$ into mass eigenstates $\tilde{t}_1/2$ is induced by the trilinear Higgs-stop-stop coupling term $A_t$ and
the Higgs-mixing parameter \( \mu \). The top-squark mass matrix squared is given by 

\[
M^2 = \begin{pmatrix}
    m_t^2 & A_{LL} \\
    m_t B_{LR} & m_t^2 + C_{RR}
\end{pmatrix},
\]

with \( m_t \) denoting the top-quark mass and 

\[
A_{LL} = \left( \frac{1}{2} - \frac{2}{3} \sin^2 \theta_W \right) m_Z^2 \cos 2\beta + m_{\tilde{Q}_3}^2, \\
B_{LR} = A_t - \mu \cot \beta, \\
C_{RR} = \frac{2}{3} \sin^2 \theta_W m_Z^2 \cos 2\beta + m_{\tilde{U}_3}^2.
\]

Here, \( \tan \beta \) is the ratio of the vacuum expectation values of the two Higgs doublets and \( m_{\tilde{Q}_3}, m_{\tilde{U}_3} \) are the soft-breaking mass terms for left- and right-handed top-squarks, respectively.

The top-squark mass eigenvalues are obtained by diagonalizing the mass matrix,

\[
M^2 = \begin{pmatrix}
    m_{\tilde{t}_1}^2 & 0 \\
    0 & m_{\tilde{t}_2}^2
\end{pmatrix}, \quad U = \begin{pmatrix}
    \cos \theta_{\tilde{t}} & \sin \theta_{\tilde{t}} \\
    -\sin \theta_{\tilde{t}} & \cos \theta_{\tilde{t}}
\end{pmatrix},
\]

\[
m_{\tilde{t}_{1,2}}^2 = m_t^2 + \frac{1}{2} \left( A_{LL} + C_{RR} + \sqrt{(A_{LL} - C_{RR})^2 + 4m^2_{\tilde{t}} B_{LR}^2} \right),
\]

and the mixing angle \( \theta_{\tilde{t}} \) is determined by

\[
\tan 2\theta_{\tilde{t}} = \frac{2m_t B_{LR}}{A_{LL} - C_{RR}}.
\]

At hadron colliders, diagonal pairs of top-squarks can be produced at leading order in QCD in two classes of partonic subprocesses,

\[
\begin{align*}
    gg &\rightarrow \tilde{t}_1 \tilde{t}_1^* \\
    q\bar{q} &\rightarrow \tilde{t}_1 \tilde{t}_1^* \quad \text{and} \quad \tilde{t}_2 \tilde{t}_2^*,
\end{align*}
\]

where \( q\bar{q} \) denotes representatively the contributing quark flavors. The corresponding Feynman diagrams for the example of \( \tilde{t}_1 \tilde{t}_1^* \) production are shown in the appendix, Fig. [A.1].

As already mentioned, mixed pairs cannot be produced at lowest order since the \( g \tilde{t}^* \) and \( gg \tilde{t}^* \) vertices are diagonal in the chiral as well as in the mass basis.

The differential partonic cross sections for the subprocesses,

\[
d\hat{\sigma}^{gg,qq}(s) = \frac{1}{16\pi s^2} \sum |\mathcal{M}_0^{gg,qq}(s, \hat{s}, \hat{u})|^2 d\hat{s},
\]

can be expressed in terms of the squared and spin-averaged lowest-order matrix elements, as explicitly given by [10],

\[
\sum |\mathcal{M}_0^{gg}|^2 = \frac{1}{4} \cdot \frac{1}{64} \cdot 32\pi^2 \alpha_s^2 \left( C_0 \left( 1 - \frac{\hat{t}_{\bar{u}} \hat{t}_r}{s^2} \right) - C_K \right) \left[ 1 - \hat{s} m_{\tilde{t}_1}^2 \left( \frac{\hat{t}_r \hat{u}_r}{\hat{t}_{\bar{u}} \hat{u}_r} \right) \right],
\]

\[
\sum |\mathcal{M}_0^{qq}|^2 = \frac{1}{4} \cdot \frac{1}{64} \cdot 32\pi^2 \alpha_s^2 N C_F \frac{\hat{t}_r \hat{u}_r - m_{\tilde{t}_1}^2 \hat{s}}{\hat{s}^2},
\]

where \( \hat{s}, \hat{t}, \hat{u} \) are the Mandelstam variables.
with $\hat{t}_r = \hat{t} - m^2_{\tilde{t}_i}$, $\hat{u}_r = \hat{u} - m^2_{\tilde{u}_i}$, where $\hat{s}$, $\hat{t}$, $\hat{u}$ are the usual Mandelstam variables. $i = 1, 2$ denotes the two mass eigenstates. The $SU(3)$ color factors are given by $N = 3$, $C_0 = N(N^2 - 1)/2 = 24$, $C_K = (N^2 - 1)/N = 8/3$ and $C_F = (N^2 - 1)/(2N) = 4/3$.

The differential cross section at the hadronic level for the process $AB \to \tilde{t}_i \tilde{t}_i^*$, $i = 1, 2$, is related to the partonic cross sections through

$$d\sigma^{AB}(S) = \sum_{a,b} \int_{\tau_0}^{1} d\tau dL_{AB}^{ab} d\hat{\sigma}^{ab}_{0}(\hat{s}), \quad (2.10)$$

with $\tau = \hat{s}/S$, $S$ ($\hat{s}$) being the hadronic (partonic) center-of-mass energy squared and $\tau_0 = 4m^2_{\tilde{t}_i}/S$ is the production threshold. The sum over $a, b$ runs over all possible initial partons. The parton luminosities are given by

$$dL_{ab}^{AB} = \frac{1}{1 + \delta_{ab}} \int_{\tau}^{1} dx \left[ f_{a/A}(x, \mu_F) f_{b/B}(\frac{\tau}{x}, \mu_F) + f_{b/A}(\frac{\tau}{x}, \mu_F) f_{a/B}(x, \mu_F) \right], \quad (2.11)$$

where the parton distribution functions (PDFs) $f_{a/A}(x, \mu_F)$ parameterize the probability of finding a parton $a$ inside a hadron $A$ with fraction $x$ of the hadron momentum at a factorization scale $\mu_F$.

3. Classification of EW NLO corrections

In the following we describe the calculation of EW contributions to top-squark pair production at NLO. For the treatment of the Feynman diagrams and corresponding amplitudes we make use of FeynArts 3.2 [15] and FormCalc 5.2 with LoopTools 2.2 [16], based on Passarino-Veltman reduction techniques for the tensor loop integrals [17], which were further developed for 4-point integrals in [18]. Higgs properties are computed with FeynHiggs 2.5.1 [19].

The supersymmetric final state does not allow to separate the SM-like corrections from the superpartner contributions which are necessary for the cancellation of ultra-violet (UV) singularities. As the photino is not a mass eigenstate of the theory, it is also not possible to split the EW corrections into a QED and a weak part, which is often the case in SM processes. In order to obtain a UV finite result, we have to deal with the complete set of EW virtual corrections including photonic contributions. These are infrared (IR) singular and thus also the real photonic corrections have to be taken into account. In addition, a photon-induced subclass of corrections appears at NLO as an independent production channel.

3.1 Virtual corrections

The virtual corrections arise from self-energy, vertex, box, and counter-term diagrams. These are shown in the appendix, in Fig. A.3 for the $q\bar{q}$ annihilation and and in Fig. A.4 for the gluon fusion channel, respectively. Getting an UV finite result requires renormalization of the involved quarks and top-squarks. The renormalized quark and squark self-energies are obtained from the unrenormalized initial quark self-energies

$$\Sigma^q(p) = \hat{p}_\perp \Sigma_L^q(p^2) + \hat{p}_\perp \Sigma_R^q(p^2) + m_q \Sigma_S^q(p^2), \quad (3.1)$$
according to

\[ \hat{\Sigma}_{q}^L(p^2) = \Sigma_{q}^L(p^2) + \delta Z_{q}^L, \]
\[ \hat{\Sigma}_{R}^q(p^2) = \Sigma_{R}^q(p^2) + \delta Z_{R}^q, \]
\[ \hat{\Sigma}_{S}^q(p^2) = \Sigma_{S}^q(p^2) - \frac{1}{2} \left( \delta Z_{L}^q + \delta Z_{R}^q \right) + \frac{\delta m_{q}}{m_{q}}, \] (3.2)

and from the top-squark self-energies \( \hat{\Sigma}_{\tilde{t}}(k^2) \) (for \( i = 1, 2 \)), according to

\[ \hat{\Sigma}_{\tilde{t}}(k^2) = \Sigma_{\tilde{t}}(k^2) + k^2 \delta Z_{\tilde{t}} - m_{\tilde{t}}^2 \delta Z_{\tilde{t}} - \delta m_{\tilde{t}}^2, \] (3.3)

with the renormalized quantities denoted by the symbol \( \hat{\Sigma} \).

The full set of virtual contributions is UV finite after including the proper counter-terms for self-energies, quark vertices, and squark triple and quartic vertices, as listed in the following set of Feynman rules:

\[ i\delta \Sigma_{\tilde{t}} = i \left( k^2 \delta Z_{\tilde{t}} - m_{\tilde{t}}^2 \delta Z_{\tilde{t}} - \delta m_{\tilde{t}}^2 \right), \] (3.4)

\[ i\delta \Lambda_{\mu} = -ig_{s} T^{c} (k + k')_{\mu} \delta Z_{\tilde{t}}, \] (3.5)

\[ i\delta \Lambda_{S}^{SSVV} = \frac{1}{2} g_{s}^{2} \left( \frac{1}{3} \delta_{ab} + d_{abc} T^{c} \right) g_{\mu\nu} \delta Z_{\tilde{t}}^{c}, \] (3.6)

\[ i\delta \Lambda_{\mu}^{q} = -ig_{s} T^{c} \gamma_{\mu} (\omega_{-} \delta Z_{q}^{L} + \omega_{+} \delta Z_{q}^{R}), \] (3.7)

where \( k, k' \) denote the momenta of top-squarks (in the direction of arrows), \( a, b, \) and \( c \) are the gluonic color indices, \( T^{c} \) and \( d_{abc} \) are the color factors (we skip the fermionic and sfermionic color indices), and \( \omega_{\pm} = (1 \pm \gamma_{5})/2 \) are the projection operators. The renormalization constants are fixed within the on-shell renormalization scheme as follows,

\[ \delta m_{\tilde{t}}^2 = \text{Re} \Sigma_{\tilde{t}}(m_{\tilde{t}}^2), \] (3.8)

\[ \delta Z_{\tilde{t}} = -\frac{d}{dk^2} \text{Re} \Sigma_{\tilde{t}}(k^2) \bigg|_{k^2 = m_{\tilde{t}}^2}, \] (3.9)

\[ \delta Z_{L,R}^q = -\text{Re} \Sigma_{L,R}^q(m_{q}^2) - m_{q}^2 \frac{\partial}{\partial p^2} \text{Re} \left[ \Sigma_{L}^q(p^2) + \Sigma_{R}^q(p^2) + 2\Sigma_{S}^q(p^2) \right] \bigg|_{p^2 = m_{q}^2}. \] (3.10)
There is no renormalization of the gluon field at $O(\alpha)$. Also, the strong coupling constant does not need renormalization since UV singularities cancel in the sum of 3- and 4-point functions and their corresponding counter-terms from quark and squark field renormalization (see Figs. A.3 and A.4 in the appendix).

Loop diagrams involving virtual photons generate IR singularities. According to Bloch-Nordsieck [20], IR singular terms cancel against their counterparts in the real photon corrections. To regularize the IR singularities we introduce a fictitious photon mass $\lambda$. In case of external light quarks, also collinear singularities occur if a photon is radiated off a massless quark in the collinear limit. We therefore keep non-zero initial-state quark masses $m_q$ in the loop integrals. This gives rise to single and double logarithmic contributions of quark masses. The double logarithms cancel in the sum of virtual and real corrections, single logarithms, however, survive and have to be treated by means of the factorization.

In the $gg$ fusion channel, IR singularities originate only from final-state photon radiation, and mass singularities do not occur. In the $q\bar{q}$ annihilation subprocess, the IR singular structure is extended by the contributions related to the gluons which appear in the 4-point UV finite loop integrals. There are two types of IR singular box contributions (Fig. A.3 c). The first group is formed by the gluon–photon box diagrams with two sources of IR singularities, one related to photons, the other to gluons. The second group consists of the gluon–$Z$ box diagrams with IR singularities originating from the gluons only. There is also an IR finite group of $O(\alpha s)$ box diagrams which consists of gluino–neutralino loops (Fig. A.3 d). Owing to the photon-like appearance of the gluon in the box contributions, the gluonic IR singularities can be handled in analogy to the photon IR singularities.

### 3.2 Real corrections

To compensate IR singularities in the virtual EW corrections, contributions with real photon (Fig. A.5 a and c) and real gluon radiation are required. In case of $gg$ fusion, only photon bremsstrahlung is needed, whereas in the $q\bar{q}$ annihilation channel, also gluon bremsstrahlung at the appropriate order $O(\alpha s^2)$ has to be taken into account (Fig. A.6) to cancel the IR singularities related to the gluon. The necessary contributions originate from the interference of QCD and EW Born level diagrams, which vanishes at LO. Not all of the interference terms contribute. Due to the color structure, only the interference between initial and final state gluon radiation is non-zero.

Including the EW–QCD interference in the real corrections does not yet lead to an IR finite result. Also the IR singular QCD-mediated box corrections interfering with the $O(\alpha)$ photon and $Z$-boson tree-level diagrams are needed. Besides the gluonic corrections there are also the IR finite QCD-mediated box corrections, which contain gluinos in the loop. Interfered with the $O(\alpha)$ tree-level diagrams, these also give contributions of the respective order of $O(\alpha s^2)$. The set of all $O(\alpha s^2)$ diagrams is shown in Fig. A.7.

So far we have mentioned only the IR singular bremsstrahlung contributions. However, there are also IR finite real corrections to both gluon fusion and $q\bar{q}$ annihilation processes. In addition to the photon radiation off the off-shell top-squark there are photon radiation contributions originating from the quartic gluon–photon–squark–squark coupling. These contributions do not have to be regularized since they are not singular (Fig. A.5 b and d).
The treatment of IR singular bremsstrahlung is done using the phase space slicing method. Imposing cut-offs $\Delta E$ on the photon/gluon energy and $\Delta \theta$ on the angle between the photon/gluon and radiating fermion, the photonic/gluonic phase space is split into soft and collinear parts which contain singularities and a non-collinear, hard part which is free of singularities and is integrated numerically. The sum of virtual and real contributions, each of them dependent on the cut-off parameters $\Delta E$ and $\Delta \theta$, has to provide a fully independent result. To ensure this we perform numerical checks.

In the singular regions, the squared matrix elements for the radiative processes factorize into the lowest-order squared matrix elements and universal factors containing the singularities.

### 3.2.1 Soft singularities

The soft-photon part of the radiative cross section in the $q\bar{q}$ annihilation channel

$$d\hat{\sigma}_{\text{soft},\gamma}^{qq}(\hat{s}) = \frac{\alpha}{\pi} \left( e_q^2 \delta_{\text{soft}}^{\text{in}} + e_t^2 \delta_{\text{soft}}^{\text{fin}} + 2e_q e_t \delta_{\text{soft}}^{\text{int}} \right) d\hat{\sigma}_0^{qq}(\hat{s}),$$

and in the $gg$ fusion channel

$$d\hat{\sigma}_{\text{soft},\gamma}^{gg}(\hat{s}) = \frac{\alpha}{\pi} e_t^2 \delta_{\text{soft}}^{\text{fin}} d\hat{\sigma}_0^{gg}(\hat{s}),$$

can be expressed using universal factors, $\delta_{\text{soft}}^{\text{in,fin,int}}$, which refer to the initial state radiation, final state radiation or interference of initial and final state radiation, respectively. $d\hat{\sigma}_0^{qq,gg}$ denote the corresponding partonic lowest order cross sections. The singular universal factors, similar to those in [21], read as follows,

$$\delta_{\text{soft}}^{\text{in}} = \left[ \ln \delta_{\text{s}}^2 - \ln \frac{\lambda^2}{\hat{s}} \right] \left[ \ln \frac{\hat{s}}{m_q^2} - 1 \right] - \frac{1}{2} \ln^2 \frac{\hat{s}}{m_q^2} + \ln \frac{\hat{s}}{m_q^2} - \frac{\pi^2}{3},$$

$$\delta_{\text{soft}}^{\text{fin}} = \left[ \ln \delta_{\text{s}}^2 - \ln \frac{\lambda^2}{\hat{s}} \right] \left[ \frac{\hat{s} - 2m_{t_i}^2}{\hat{s}\beta} \ln \left( \frac{1 + \beta}{1 - \beta} \right) - 1 \right] + \frac{1}{\beta} \ln \left( \frac{1 + \beta}{1 - \beta} \right)$$

$$- \frac{\hat{s} - 2m_{t_i}^2}{\hat{s}\beta} \left[ 2\text{Li}_2 \left( \frac{2\beta}{1 + \beta} \right) + \frac{1}{2} \ln^2 \left( \frac{1 + \beta}{1 - \beta} \right) \right],$$

$$\delta_{\text{soft}}^{\text{int}} = \left[ \ln \delta_{\text{s}}^2 - \ln \frac{\lambda^2}{\hat{s}} \right] \ln \left( \frac{1 - \beta \cos \theta}{1 + \beta \cos \theta} \right) - \text{Li}_2 \left( 1 - \frac{\beta}{1 + \beta \cos \theta} \right)$$

$$- \text{Li}_2 \left( 1 - \frac{1 + \beta}{1 - \beta \cos \theta} \right) + \text{Li}_2 \left( 1 - \frac{1 - \beta}{1 + \beta \cos \theta} \right) + \text{Li}_2 \left( 1 - \frac{1 + \beta}{1 + \beta \cos \theta} \right).$$

(3.13)

Here, $e_q$ and $e_t$ are the electric charges of the initial quark and of the top-squark, respectively, and we introduced $\delta_{s} = 2\Delta E/\sqrt{\hat{s}}$, where $\Delta E$ is the slicing parameter for the maximum energy a soft photon may have. For application purposes, it is useful to express Eq. (3.13) in terms of Mandelstam invariants, $\hat{t}$ and $\hat{u}$, using the relations

$$\hat{t}, \hat{u} = m_{t_i}^2 - \frac{\hat{s}}{2} (1 \mp \beta \cos \theta), \quad \beta = \sqrt{1 - \frac{4m_{t_i}^2}{\hat{s}}}. \quad (3.14)$$
The soft-gluon part for the $q\bar{q}$ channel can be written in a way similar to (3.11), but with a different arrangement of the color matrices,

$$
\frac{d\hat{\sigma}_{\text{soft},g}^{q\bar{q}}(\hat{s})}{\hat{s}} = \frac{\alpha_s}{\pi} \delta_{\text{soft}}^{\text{int}} \left[ T_{ij}^a T_{ji}^b T_{lm}^\gamma \tau_{ml}^b \right] \times 2 \text{Re} \sum \left( \tilde{M}_{\bar{u},g}^{q\bar{q}} + \tilde{M}_{\bar{u},\gamma}^{q\bar{q}} + \tilde{M}_{\bar{u},Z}^{q\bar{q}} \right) \frac{d\hat{t}}{16\pi \hat{s}^2},
$$

(3.15)

with $\tilde{M}$ denoting the “Born” matrix elements for $g$, $\gamma$ and $Z$ exchange where the color matrices are factorized off. Explicitly, it can be written as follows,

$$
\frac{d\hat{\sigma}_{\text{soft},g}^{q\bar{q}}(\hat{s})}{\hat{s}} = \frac{\alpha_s}{\pi} \delta_{\text{soft}}^{\text{int}} NC_F \left[ \frac{8e_q e_t}{\hat{s}^2} + \left( \frac{(U_{1t})^2 - 2e_t \sin^2 \theta_W (\epsilon - 4e_q \sin^2 \theta_W)}{\sin^2 \theta_W \cos^2 \theta_W \hat{s} (\hat{s} - m^2_Z)} \right) \right] \times \frac{16\pi^2 \alpha_s}{4 \cdot 9} \left[ (\hat{t} - m_{z_i}^2) (\hat{u} - m_{t_i}^2) - m_{z_i}^2 \hat{s} \right] \frac{d\hat{t}}{16\pi \hat{s}^2},
$$

(3.16)

involving the top-squark mixing matrix of Eq. (2.4), and $\epsilon = \pm 1$ for up- and down-type initial quarks, respectively.

### 3.2.2 Collinear singularities

Collinear singularities arise only from initial-state photon radiation in $q\bar{q}$ annihilation. The collinear part of the $2 \to 3$ cross section is proportional to the Born cross section of the hard process with reduced momentum of one of the partons. Assuming that parton $a$ with momentum $p_a$ radiates off a photon with $p_\gamma = (1 - z)p_a$, the parton momentum available for the hard process is reduced to $zp_a$. Accordingly, the partonic energy of the total process inclusive photon radiation is $\hat{s} = (p_a + p_\gamma)^2 = \hat{\tau} S$, and for the hard process the reduced partonic energy is $\hat{s} = (zp_a + p_b)^2 = \tau S$. The ‘total’ and ‘hard’ variables are thus related by $\hat{s} = z\hat{s}$ and $\tau = z\hat{\tau}$.

Having defined these variables, the partonic cross section in the collinear cones can be written in the following way

$$
\frac{d\hat{\sigma}_{\text{coll}}^{q\bar{q}}(\hat{s})}{\hat{s}} = \frac{\alpha_s}{\pi} e_q^2 \int_0^{1-\delta_\theta} dz \frac{d\hat{\sigma}_{\text{soft}}^{q\bar{q}}(\hat{s})}{\hat{s}} \kappa_{\text{coll}}(z),
$$

(3.17)

with

$$
\kappa_{\text{coll}}(z) = \frac{1}{2} P_{qq}(z) \left[ \ln \left( \frac{\hat{s}}{m_q^2} \frac{\delta_\theta}{2} \right) - 1 \right] + \frac{1}{2}(1 - z),
$$

where $P_{qq}(z) = (1 + z^2)/(1 - z)$ is an Altarelli-Parisi splitting function and $\delta_\theta$ is the cutoff parameter to define the collinear region by $\cos \theta > 1 - \delta_\theta$. The Born cross section refers to the hard scale $\hat{s}$, whereas in the collinear factor the total energy $\hat{s}$ is the scale needed. In order to avoid an overlap with the soft region, the upper limit of the $z$-integration in Eq. (3.17) is reduced from $z = 1$ to $z = 1 - \delta_\theta$.

As already mentioned, after adding virtual and real corrections, the mass singularity in Eq. (3.17) does not cancel and has to be absorbed into the (anti-)quark density functions. This can be formally achieved by a redefinition of the parton density functions (PDFs) at
NLO QED as follows [22, 25, 26],

\[
f_{a/A}(x) \rightarrow f_{a/A}(x, \mu_F) + f_{a/A}(x, \mu_F) \alpha \pi e_q^2 \kappa_{\text{soft}} \int_x^{1-\delta_s} \frac{dz}{z} f_{a/A}(\frac{x}{z}, \mu_F) \kappa_{\text{coll}}(z)
\]

with \( \kappa_{\text{soft}} = -1 + \ln \delta_s + \ln^2 \delta_s - \ln \left( \frac{\mu_F^2}{m_Z^2} \right) \left[ \frac{3}{4} + \ln \delta_s \right] + \frac{1}{4} \lambda_{sc} \left[ 9 + \frac{2\pi^2}{3} + 3 \ln \delta_s - 2 \ln^2 \delta_s \right], \)

\[\kappa_{\text{coll}}(z) = \frac{1}{2} P_{qq}(z) \left[ \ln \left( \frac{m_Z^2 (1-z)^2}{\mu_F^2} \right) + 1 \right] - \frac{1}{2} \lambda_{sc} \left[ P_{qq}(z) \ln \frac{1-z}{z} - \frac{3}{2} \frac{1}{1-z} + 2z + 3 \right]. \]

The QED factorization scheme dependent \( \lambda_{sc} \)-parameter is \( \lambda_{sc} = 0 \) in the \( \overline{\text{MS}} \)-scheme and \( \lambda_{sc} = 1 \) in the \( \text{DIS} \) scheme.

At the hadronic level, we define the collinear part of the real corrections for the case where parton \( a \) radiates off a collinear photon, in the following way by use of Eq. (3.18),

\[
d\sigma_{\text{coll}}(S) = \alpha \pi e_q^2 \int d\tau \int_x^{1-\delta_s} \frac{dz}{z} d\hat{\sigma}_{0}(\hat{s}) \left[ \kappa_{\text{coll}}(z) + \kappa_{\text{coll}}^{\text{DF}}(z) \right] \times \left[ f_{a/A}(\frac{x}{z}, \mu_F) f_{b/B}(\frac{\tau}{x}, \mu_F) + f_{b/A}(\frac{\tau}{x}, \mu_F) f_{a/B}(\frac{x}{z}, \mu_F) \right],
\]

where the lower limit of the \( z \)-integration is constrained to \( x \), since the parton momentum fraction \( x/z \) has to be smaller than unity. The integral is free of any mass singularity,

\[
\kappa_{\text{coll}}(z) + \kappa_{\text{coll}}^{\text{DF}}(z) = \frac{1}{2} P_{qq}(z) \ln \left( \frac{\hat{s} (1-z)^2}{\mu_F^2} \right) \left[ \lambda_{sc} \left[ \frac{1}{2} (1-z) - \frac{1}{2} \frac{1}{1-z} + 2z + 3 \right] \right].
\]

The \( \kappa_{\text{soft}}^{\text{DF}} \)-term in Eq. (3.18) cancels the mass singularities owing to soft photons that remain in the sum of the virtual corrections and the soft correction factor \( \delta_{\text{soft}}^{in} \) in Eq. (3.13).

### 3.3 Photon-induced top-squark pair production

We also consider the photon-induced mechanisms of the top-squark pair production. At the hadronic level, these processes vanish at leading order owing to the non-existence of a photon distribution inside the proton. At NLO in QED, however, a non-zero photon density arises in the proton as a direct consequence of including higher order QED effects into the evolution of PDFs, leading thus to non-zero photon-induced hadronic contributions.

Feynman diagrams corresponding to the photon–gluon partonic process are illustrated in Fig. A.2. Although these are contributions of different order, they are tree-level contributions to the same hadronic final state and thus deserve a closer inspection. The differential
cross section for this subprocess is

\[ d\hat{\sigma}^{g\gamma}_0(\hat{s}) = \frac{1}{16\pi s^2} \sum \left| \mathcal{M}^{g\gamma}_0(\hat{s}, \hat{t}_r, \hat{u}_r) \right|^2 d\hat{t} \left( \frac{\hat{s} m_{\tilde{t}_1}^2}{\hat{t}_r \hat{u}_r} \right) \left( 1 - \frac{\hat{s} m_{\tilde{t}_1}^2}{\hat{t}_r \hat{u}_r} \right), \]

expressed in terms of the reduced Mandelstam variables \( \hat{t}_r = \hat{t} - m_{\tilde{t}_1}^2, \hat{u}_r = \hat{u} - m_{\tilde{t}_1}^2 \). The quark-photon partonic processes represent contributions of higher order and we do not include them in our discussion here.

The photon density is part of the PDFs at NLO QED, which have become available only recently [27]; here we present the first study of these effects on the top-squark pair production.

4. Numerical results

For the numerical discussion we focus on the production of light top-squark pairs \( \tilde{t}_1 \tilde{t}_1 \) in proton-proton collisions for LHC energies. We present the results in terms of the following hadronic observables: the integrated cross section, \( \sigma \), the differential cross section with respect to the (photon inclusive) invariant mass of the top-squark pair, \( (d\sigma/dM_{inv}) \), the differential cross sections with respect to the transverse momentum, \( (d\sigma/dp_T) \), to the rapidity, \( (d\sigma/dy) \), and to the pseudo-rapidity, \( (d\sigma/d\eta) \), of one of the final state top-squarks.

For getting experimentally more realistic results for the cross sections we also apply typical sets of kinematical cuts. A study of the dependence on the various SUSY parameters is given towards the end of this section.

The NLO differential cross section at the hadron level is combined from the contributing partonic cross sections by convolution and summation as follows,

\[ d\sigma^{pp}(S) = \int_{\tau_0}^{1} d\tau \left\{ \sum_i \frac{d\mathcal{L}^{pp}_i}{d\tau} \hat{\sigma}^{q\bar{q}i}(\hat{s}) + \frac{d\mathcal{L}^{gg}}{d\tau} \hat{\sigma}^{gg}(\hat{s}) + \frac{d\mathcal{L}^{g\gamma}}{d\tau} \hat{\sigma}^{g\gamma}_0(\hat{s}) \right\}, \]

where \( d\hat{\sigma}^{q\bar{q}i} \) and \( d\hat{\sigma}^{gg} \) represent full one-loop results, including complete virtual and real corrections, and \( d\hat{\sigma}^{g\gamma}_0 \) is given in Eq. (3.21). The respective parton luminosities refer to Eq. (2.11).

One has to take care of the fact that each top-squark observed in the laboratory system under a certain angle \( \theta \) can originate from two different constellations at parton level: parton \( a(b) \) out of hadron \( A(B) \) and vice-versa, corresponding to \( \theta \rightarrow (\pi - \theta) \). Both parton level configurations have to be added correctly for hadronic distributions (for explicit formulas see e.g. [28]). Note that the two boost factors \( \beta \) relating the two partonic center-of-mass (c.m.) systems with the laboratory system differ by a relative sign, as do the rapidity and the pseudo-rapidity of each particle.

Assuming that the forward-scattered parton \( a \) carries the momentum fraction \( x \) of hadron \( A \) and the backward-scattered parton \( b \) the momentum fraction \( \tau/x \) of hadron \( B \),

\[ \hat{t}_r = \hat{t} - m_{\tilde{t}_1}^2, \hat{u}_r = \hat{u} - m_{\tilde{t}_1}^2. \]
the boost factor $\beta$ is given by

$$\beta = \frac{x - \tau / x}{x + \tau / x}. \quad (4.2)$$

The rapidity of one of the final state top-squarks in the laboratory system, $y(\equiv y_{\tilde{t}_1}^*)$, is related to the rapidity in the partonic c.m. frame, $y^{cm} = \text{artanh}(p_z^{cm}/E^{cm})$, via a Lorentz transformation,

$$y = y^{cm} - \text{artanh}(-\beta) = y^{cm} + \frac{1}{2} \ln \frac{x^2}{\tau}. \quad (4.3)$$

The pseudo-rapidity $\eta$ is related to $\eta^{cm} = -\ln(\tan(\theta^{cm}/2)$ in the c.m. frame via

$$\eta = \text{arsinh} \left( \frac{1}{2} \sqrt{\frac{m_{\tilde{t}_1}^2}{p_T^2} + \cosh^2(\eta^{cm}) \left( \frac{x}{\sqrt{\tau}} - \frac{\sqrt{\tau}}{x} \right)} + \frac{1}{2} \sinh \eta^{cm} \left( \frac{\sqrt{\tau}}{x} + \frac{x}{\sqrt{\tau}} \right) \right), \quad (4.4)$$

which can be derived using the representation

$$p = \left( \sqrt{m_{\tilde{t}_1}^2 + p_T^2 \cosh^2 \eta}, 0, p_T, p_T \sinh \eta \right) \quad (4.5)$$

for the top-squark momentum $p \equiv p_{\tilde{t}_1}$. Since the final state particles are massive, rapidity and pseudo-rapidity do not coincide; in the limit $m \rightarrow 0$ one obtains $\eta = y$.

### 4.1 Input parameters and conventions

Our Standard Model input parameters are chosen in correspondence with [29],

$$M_Z = 91.1876 \text{ GeV}, \quad M_W = 80.403 \text{ GeV},$$

$$\alpha^{-1} = 137.036, \quad \alpha(M_Z)^{-1} = 127.934, \quad G_F = 1.1664 \times 10^{-5} \text{ GeV}^{-2}, \quad (4.6)$$

$$m_t = 172.7 \text{ GeV}, \quad m_b = 4.7 \text{ GeV}, \quad m_b(m_b) = 4.2 \text{ GeV}. \quad$$

All lepton and all other quark masses are set to zero unless where they are used for regularization. As a reference we consider the SPA SUSY parameter point SPS 1a’ [29], unless stated otherwise. The current value of the top-quark mass, $m_t = 170.9 \pm 1.9 \text{ GeV}$ [30], increases the top-squark mass $m_{\tilde{t}_1}$ by 0.2%, which reduces the total cross section by $\approx 1\%$. The changes for the relative corrections are completely negligible.

For the parton distributions, we use the set MRST 2004 QED [27], as already mentioned previously. Factorization and renormalization scales are chosen equal, $\mu_F = \mu_R = 2m_{\tilde{t}_1}$. 

### 4.2 Hadronic cross sections and distributions

In Table 1 we show results for the cross section for top-squark pair production at the LHC within four different scenarios, chosen out of the SPS benchmark scenarios of the minimal SUGRA type [29, 31]. The integrated hadronic cross sections at leading order, $\sigma^{LO}$, the absolute size of the EW corrections corresponding to the difference between the LO and NLO cross sections, $\Delta \sigma^{NLO}$, and the relative corrections, $\delta$, given as the ratio of NLO corrections to the respective LO contributions, are presented for the gg fusion, the
Table 1: Numerical results for the integrated cross sections for light top-squark pair production at the LHC within different SPS scenarios [29, 31].

| Scenario | Channel | $\sigma^{LO}$ [fb] | $\Delta\sigma^{NLO}$ [fb] | $\delta = \frac{\Delta\sigma^{NLO}}{\sigma^{LO}}$ |

|          | **Total**   | **34860**        | **891**           | **2.6%**          |

$q\bar{q}$ annihilation, and the $g\gamma$ fusion channel separately. The $g\gamma$ channel contributes only at NLO. For the $q\bar{q}$ channel, also the numbers for the $O(\alpha^2)$ pure electroweak Born level contributions are given in brackets. These are typically smaller by one order of magnitude compared to the EW NLO corrections.

In scenarios where the top-squark $\tilde{t}_1$ is of intermediate or high mass (as SPS 1a, SPS 1a’, and SPS 2) the NLO contributions are below 1%. The corrections to the $q\bar{q}$ and the $gg$ channels are negative, whereas the $g\gamma$ contribution is always positive and of the same size as the other corrections or even larger. The situation is different in scenarios where the top-squark is very light, i.e. lighter than half of $m_{H^0}$, the mass of the heavier neutral Higgs boson $H^0$, where a large fraction of the squarks appears through production and decay of $H^0$ particles. This is the case in the SPS 5 scenario [$m_{\tilde{t}_1} = 204$ GeV, $m_{H^0} = 694$ GeV and $\Gamma(H^0) = 9.7$ GeV derived from FeynHiggs [19]]. The electroweak contributions in the $gg$ channel are positive and slightly larger than the $g\gamma$ fusion contribution.

The interplay of the three production channels is illustrated in Fig. 1 where the absolute EW contributions $\Delta\sigma$ per channel are shown as distributions with respect to $p_T$, $M_{inv}$, $y$, or $\eta$. Owing to the alternating signs, compensations occur where in particular the $g\gamma$ channel plays an important role.

For realistic experimental analyses, cuts on the kinematically allowed phase space of
Figure 1: Comparison of EW NLO contributions from the various parton channels, for the distributions of transverse momentum $p_T(\tilde{t})$, invariant mass of the stop pair, rapidity $y(\tilde{t})$, and pseudo-rapidity $\eta(\tilde{t})$ (from upper left to lower right). $y$ and $\eta$ are given in the laboratory frame. For $gg$ fusion and $q\bar{q}$ annihilation, $\Delta$ denotes the difference between NLO and LO distributions ($\Delta\sigma \equiv \Delta\sigma^{NLO} \equiv \sigma_0^{NLO}$), for $g\gamma$ one has $\Delta\sigma \equiv \sigma_0^{g\gamma}$.

For the top-squarks to be applied. They can be realized by a lower cut on the transverse momenta of the final-state particles to focus on high-$p_T$ jets. Moreover, detectability of the final state particles requires a minimal angle between the particles and the beam axis. Therefore, we set a cut on the pseudo-rapidity of the top-squarks restricting the scattering angle $\theta$ to a central region. Two exemplary sets of cuts are applied in the following figures (Figs. 2 – 5),

- cuts 1: $p_T \geq 150$ GeV and $|\eta| \leq 2.5$ (i.e. $9.4^o \leq \theta \leq 170.6^o$),
- cuts 2: $p_T \geq 250$ GeV and $|\eta| \leq 2.5$.

The differential cross sections and the influence of cuts are the content of Figs. 2 and 3. Displayed are the hadronic cross-sections at NLO, differential with respect to $p_T$, $M_{inv}$ and to $y$, $\eta$, respectively. Both the full (unconstrained) distributions and the distributions with cuts applied are shown. The reduction of the integrated cross section owing to the application of cuts is summarized in Table 2.
Figure 2: Comparison of EW NLO differential hadronic cross sections (solid lines) and the distributions where kinematical cuts on the final top-squarks are applied for all three production channels, $gg$ fusion (upper red plots), $q\bar{q}$ channels (middle blue plots), and $g\gamma$ fusion (lower green plots). Cuts 1 (dashed lines): $p_T \geq 150$ GeV, $|\eta| \leq 2.5$, cuts 2 (dotted lines): $p_T \geq 250$ GeV, $|\eta| \leq 2.5$. Distributions with respect to the transverse momentum $p_T$ ($\tilde{t}_1$) (left) and the invariant mass of the stop pair (right) are shown for $\tilde{t}_1\tilde{t}_1$ pair production at the LHC within the SPS 1a’ scenario.

The application of cuts reduces the $gg$ and $g\gamma$ channels strongly, cutting off the peak of the $p_T$-distributions. The reduction is less pronounced in the $q\bar{q}$ channels where the $p_T$-distribution is harder. The $p_T$-cuts also shift the threshold of the invariant mass distributions towards higher values affecting again mainly the $gg$ and $g\gamma$ channels in height and shape. The situation for the rapidity distribution is similar. In the $q\bar{q}$ channel, the harder $p_T$-distribution goes along with a narrower $\eta$-distribution, as shown in the right panels of Fig. 2. Most of the top-squarks produced via $q\bar{q}$ annihilation can be found in the central region. In contrast, top-squarks from $gg$ or $g\gamma$ fusion are often produced in the strong
Figure 3: Same as Fig. 2, but with respect to the rapidity \( y(\tilde{t}_1^*) \) (left) and the pseudo-rapidity \( \eta(\tilde{t}_1^*) \) (right).

forward (or backward) direction, and the application of cuts on the pseudo-rapidity thus reduces the number of \( gg \) or \( g\gamma \) based events significantly.

In order to illustrate the numerical impact of the NLO contributions on the LO cross section, we show in Fig. 4 \( K \) factors \( K = \sigma^{NLO}/\sigma^{LO} \) for the \( gg \) and the \( q\bar{q} \) channel, respectively, as distributions with respect to \( p_T \) and \( M_{inv} \). The application of cuts influences the \( K \) factors only at low values of \( p_T \) and \( M_{inv} \). The EW corrections in the \( p_T \)-distribution reach typically \(-10\%\) in the \( gg \) channel, and \(-20\%\) in the \( q\bar{q} \) channel, for large values of \( p_T \). In the invariant mass distributions, they are somewhat smaller, but still sizeable, at the 10\% level for large \( M_{inv} \). The large effects at high \( p_T \) and \( M_{inv} \) are dominated by the double logarithmic contributions arising from virtual \( W \) and \( Z \) bosons in loop diagrams.

The small peaks visible in the \( gg \) invariant mass distribution correspond to two-particle thresholds related to \( \tilde{b}_1^*\tilde{b}_1, \tilde{b}_2^*\tilde{b}_2, \) and \( \tilde{t}_1^*\tilde{t}_2 \) pairs in \( gg \) vertex and box diagrams, illustrated
Table 2: Integrated hadronic cross section at NLO within the SPS 1a’ scenario for the different production channels. Comparison of the full (unconstrained) results and cross sections where cuts on the pseudo-rapidities $\eta$ and on the transverse momenta $p_T$ of the outgoing top-squarks are applied. The relative changes compared to the full results are given in brackets.

| channel | full result | $p_T < 150$ GeV & $|\eta| < 2.5$ [fb] | $p_T < 250$ GeV & $|\eta| < 2.5$ [fb] |
|---------|-------------|--------------------------------------|--------------------------------------|
| $gg$    | 3280        | 1643 ($-50\%$)                      | 778 ($-76\%$)                       |
| $g\bar{q}$ | 427        | 373 ($-13\%$)                       | 280 ($-34\%$)                       |
| $g\gamma$ | 58.5       | 30.6 ($-48\%$)                      | 16.2 ($-72\%$)                      |

in Fig. A.4 in the SPS 1a’ scenario, the masses of the involved squarks are $m_{\tilde{b}_1} = 460.7$ GeV, $m_{\tilde{b}_2} = 514.8$ GeV, $m_{\tilde{t}_2} = 569.4$ GeV. Thresholds from the squarks of the first two generations are CKM suppressed. The threshold effects appear also in the $p_T$-distribution, around 300 GeV, but they are smeared out and much less pronounced.

Fig. 5 shows total $K$ factors, defined as $K = (\sigma_{gg}^{NLO} + \sigma_{q\bar{q}}^{NLO} + \sigma_{g\gamma}^{NLO})/(\sigma_{gg}^{LO} + \sigma_{q\bar{q}}^{LO})$. It is obvious that, although small for the total cross section, the EW higher order contributions cannot be neglected for differential distributions where, in the high-$p_T$ and high-$M_{inv}$ range, they are of the same order of magnitude as the SUSY-QCD corrections [10].

![Figure 4](image-url)  

**Figure 4:** Same as Fig. 2, but shown are the $K$ factors, $K = \sigma_{gg}^{NLO}/\sigma_{gg}^{LO}$, for $gg$ fusion (upper plots) and $q\bar{q}$ channels (lower plots).
4.3 SUSY parameter dependence

In order to study the dependence of the EW contributions on the various SUSY parameters in more detail, we consider the ratio of the NLO contribution in each channel to the combined $gg + q\bar{q}$ Born cross section, $\delta_{tot} = \frac{\Delta \sigma_{NLO}^{gg, q\bar{q}, g\gamma}}{\sigma_{LO}^{tot}}$. We focus on those parameters that determine the top-squark mass, cf. Eq. (2.4), and vary each quantity out of the set $\tilde{m}_Q^3, \tilde{m}_U^3, \tan\beta, A_t, \mu$ around its SPS 1a' value while keeping all other parameters fixed to those of the default SPS 1a' scenario. The results are displayed in the left panels of Figs. 6 – 10. Simultaneously, we show the mass of the light top-squark $\tilde{t}_1$ as a function of the varied parameter in the respective right panels (black solid lines). The parameter configuration of the SPS 1a' scenario is marked by a vertical gray dotted line in all the figures.

We find the following general behaviors. The $g\gamma$ contributions are from tree level diagrams and the only relevant parameter is thus the top-squark mass $m_{\tilde{t}_1}$. In all scenarios, the $g\gamma$ fusion channel is as important as the EW corrections to the $q\bar{q}$ and $gg$ processes. The $q\bar{q}$ corrections, being practically always negative, involve many different SUSY particles in the loops, although the relative corrections show only small variations. The $gg$ contributions are more sensitive to the considered SUSY parameters. The plots show striking peaks (some of them are also visible in $q\bar{q}$ annihilation), which correspond to threshold effects and can be explained by the SUSY particle masses displayed at the right panels of Figs. 6 – 10. They occur in the Higgs-exchange diagrams when $m_{\tilde{t}_1} = m_{H^0}/2$ (red long-dashed lines in the figures), and in the top-squark wave function renormalization when $m_{\tilde{t}_1}$ equals the sum of masses of a neutralino and the top-quark (green dash-dotted lines) or of a chargino and the bottom-quark (blue dashed lines). The chargino-induced peaks are less pronounced than those from neutralinos and not visible in Fig. 6 and Fig. 10.

Outside of such singular parameter configurations, over a wide range of SUSY parameters, the combined EW contributions to top-squark pair production are only weakly parameter dependent.
Figure 6: Left: Relative EW corrections as a function of the soft-breaking parameter $m_{\tilde{Q}_3}$ for each of the indicated channels compared to the combined $(gg + q\bar{q})$ LO cross section in the SPS 1a’ scenario where $m_{\tilde{Q}_3}$ is varied around the SPS1a’ value (gray dotted line). Right: Mass of $\tilde{t}_1$, half of the mass of $H^0$, sums of the masses of the top-quark and $\tilde{\chi}_1^0$, $\tilde{\chi}_2^0$, and $\tilde{\chi}_3^0$, respectively, and sum of the masses of the bottom-quark and $\tilde{\chi}_2^+$ as a function of $m_{\tilde{Q}_3}$. All other parameters are chosen according to the SPS1a’ scenario.

Figure 7: Same as Fig. 6, but for variation of the soft-breaking parameter $m_{\tilde{U}_3}$.
Figure 8: Same as Fig. 6 but for variation of tan $\beta$.

Figure 9: Same as Fig. 7 but for variation of trilinear coupling parameter $A_t$.

Figure 10: Same as Fig. 8 but for variation of the Higgs parameter $\mu$. 
5. Conclusions

We have completed the NLO calculation for the $\tilde{t}\tilde{t}^\ast$ production at hadron colliders by providing the complete EW corrections at the one-loop level.

To obtain a consistent and IR-finite result, we have considered the interference terms between QCD and EW NLO terms for both virtual and real contributions. Also, a new class of photon-induced partonic processes of $\tilde{t}\tilde{t}^\ast$ production occurs, which was found to yield considerable contributions, comparable in size to the corrections to $q\bar{q}$ annihilation and $gg$ fusion or even larger.

In total, the NLO EW contributions reach in size the 10-20% level in the $p_T$ and invariant-mass distributions and are thus significant. Outside singular parameter configurations associated with thresholds, the dependence on the MSSM parameters is rather smooth.

Recently, a preprint appeared on the same topic [32], where the authors consider virtual corrections and the soft part of the real corrections, both for the $gg$ fusion channel; the hard part of the real corrections, as well as the contributions from the other channels are missing. The numerical results can therefore not directly be compared with ours at this stage.

Acknowledgments

The authors want to thank Tilman Plehn for helpful discussions and Edoardo Mirabella for cross-checking parts of the results.

Appendix

A. Feynman diagrams

We show here generic Feynman Diagrams for the pair production of lighter top-squark at $O(\alpha\alpha_s^2)$. Diagrams for $\tilde{t}_2^\ast\tilde{t}_2$ production can be constructed in complete analogy. The $q\bar{q}$ annihilation channels are exemplified by $u\bar{u}$ annihilation. Furthermore, the label $S^0$ refers to all neutral Higgs (and Goldstone) bosons $h^0$, $H^0$, $A^0$, $G^0$, and the label $S$ to all charged Higgs (and Goldstone) bosons $H^\pm$, $G^\pm$. 
Figure A.1: Feynman diagrams for top-squark pair production at the Born level via $gg$ fusion (left) and $q\bar{q}$ annihilation (right), here shown for $u$-quarks. As in the following figures, diagrams with crossed final states are not shown explicitly.

Figure A.2: Feynman diagrams for gluon-photon fusion.

Figure A.3: Feynman diagrams for virtual corrections to top-squark pair production via $q\bar{q}$ annihilation (here for $u$-quarks). The label $S^0$ refers to all neutral Higgs bosons $h^0$, $H^0$, $A^0$, $G^0$, the label $S$ to all charged Higgs bosons $H^\pm$, $G^\pm$. (a) counter-term diagrams, (b) vertex corrections, (c) IR singular box diagrams, (d) IR finite box diagram.
Figure A.4: Feynman diagrams for virtual corrections to top-squark pair production via $gg$ fusion, diagrams with crossed final states are not explicitly shown. The label $S^0$ refers to all neutral Higgs bosons $h^0, H^0, A^0, G^0$, the label $S$ to all charged Higgs bosons $H^\pm, G^\pm$. (a) counter-term diagrams, (b) vertex corrections, (c) self-energy corrections, (d) box diagrams.
Figure A.5: Feynman diagrams for real photon radiation. (a) IR divergent – (b) IR finite contributions for the $gg$ channel; (c) IR divergent – (d) IR finite contributions for the $q\bar{q}$ channels. Feynman diagrams with photon radiation off the other quark or squark and with crossed final states are not shown explicitly.

Figure A.6: Feynman diagrams for gluon bremsstrahlung from the QCD and EW Born diagrams (radiation from upper legs is not explicitly shown). Only interference terms between initial and final state gluon radiation are non-vanishing.

Figure A.7: Feynman diagrams for box contributions of $\mathcal{O}(\alpha_s^2)$ (left) interfering with electroweak Born graphs (right), here for $u\bar{u}$ annihilation.
